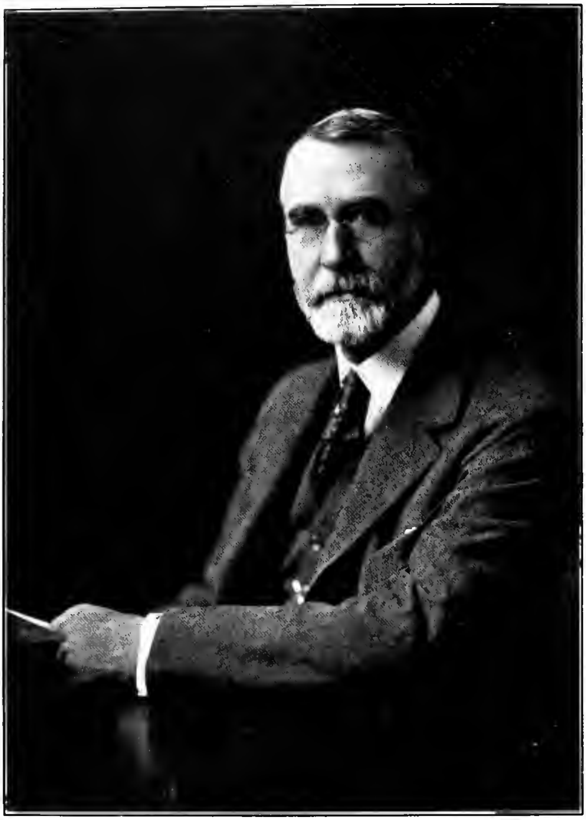
THE ENGINEERING SOCIETIES BUILDING

SHOWING THE THREE ADDED STORIES



CHARLES THOMAS MAIN

PRESIDENT 1918

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

THE JOURNAL OF

THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS

Volume 40 January 1918 Number 1

THE ANNUAL MEETING

SOME of the general meetings of the Society have excelled in the number of members and guests in attendance, some in the notable speakers and papers, some in the activity of the discussions, some in the timeliness of the topics on the program, some in the distinguished receptions held by the Society and some in the signal advances in the Society's policies; but the 38th Annual Meeting held in the Engineering Societies Building from December 4 to 7, 1917, will go down in the annals of the Society as having excelled in all of these, and in one other—the outspoken patriotism evoked by the nation's crisis in which engineers are playing no small part.

The note of patriotism sent forth by Dr. Ira N. Hollis, President of the Society for 1917, at the opening session was echoed again and again throughout the meeting and imparted to the entire proceedings the nature of a War Convention, which is likely to have a far-reaching effect upon the relations of the engineer to the Government in this emergency.

Opening Session

At the beginning of the session on Tuesday evening, President Hollis said it had been decided to omit the regular presidential address in order that there might be time to listen to one who had been honored by this nation, Hon. William H. Taft, Ex-President of the United States; and to confer Honorary Membership on one who had constructed the greatest engineering work on earth, Major-General George W. Goethals. Continuing, Dr. Hollis said:

"The Committee on Meetings decided in the late summer to change the character of our convention this year on account of the exceptional conditions in which we find ourselves. It is our first annual meeting held during a war in which we are participants. Many of our members have gone already, and many are going to voluntary service in the earnest hope of making themselvea useful to their country. Three of the Council are officers in the army: Major John H. Barr, Major William B. Gregory and Major Max Toltz; and others are serving well in civilian capacities. So much time is given by the engineers to invention, research, and manufacture for war purposes, that we could not, if we wished, conduct the usual technical program. Thus, by force of circumstances, as well as by the cheerful acquiescence of the Council and members, we turn our thoughts to public service and to discussion that will help us to see our way more clearly through this black calamity that has overtaken all the world.

"As American citizens, we hold our country to be the asylum for the oppressed, the home of opportunity for the lowly, and the land of faith in honor, truth and justice among nations, as well as among individuals.

"As engineers, our creed knows no compromise between might and right. It knows no pacifism that requires us to turn the other cheek to the assassin of all that humanity has held dear. The right to live was given to us by the Almighty, and we believe that 'they who take the sword shall perish with the sword.' Unhappily, all who are led by them share the same fate. We also believe in the justice of that penalty. We now hold the sword of the Lord and of Gideon in our hands, to use with all our strength against the barbarians of this twentieth century, so that science may be made safe for all mankind. And we have

"'Never doubted clouds would break,
Never dreamed, though right were worsted, wrong would triumph.'

"We have asked one who has held the highest office in this country, and another who has completed the greatest engineering feat on earth, to assist us in giving ourselves anew to the service of our country; but I should fail my purpose if I did not call attention to one aspect of the war.

"What are we to get out of this war? Not land, not booty, not empire, for we have disclaimed all these. We have gone in for humanity, making the great sacrifice of ourselves in the hope that the next generation may find itself the better for our share in this struggle. Our resources will be wasted on the unessentials of civilization; the blood of our young men will be shed on many battlefields, and our old people will spend their declining years in sorrow, some even in misery, as a consequence of our participation in this war. What, then, are we to get out of it?

"When we stop to think of the willingness with which thousands of men and women are working under hard conditions to train themselves for war, we find a new dignity in labor, and we gather from it a new force that can be made to supply the solvent of future struggles between capital and labor. There are many employers serving now on the battle line and many more employees serving under them, where the hardships and the deadly routine are infinitely greater than in any of the old industries. Yet the suspicions and the bitter antagonisms are gone. The relation between a good commander and his soldiers is exactly what we should have between employer and employee. Those who have been involved in a

common risk and a common service in face of death, will find a new conception of industrialism after the war is over.

"Can the virtues of war, the comradeship of the battlefield, not be made to survive in the peace that will come some day? Is it not possible to learn from this struggle that the age-long war between employer and employee never was necessary and never should have existed? Is it not possible to learn that all mankind are involved in a common fate made happier and better by mutual understanding and mutual service? Is it not possible to learn further that the power of wealth can be enjoyed only through the use to which it is put? If not, our country is sentenced to militarism for generations to come, and democracy will never be safe for any nation.

"I have been struck by a description that should stand to us as the pattern by which we may well hope to plan our lives. It is that of The Beloved Captain in one of the war books, whose career on the battle front carries a lesson to all who are leaders of other men.

'He came in the early days when we were still at recruit drills. Tall, erect, smiling, so we first saw him, and so he remained to the end. He had a smile for almost everyone, but we thought he had a different smile for us. We looked for it, and we were never disappointed. It meant that we were his men and that he was proud of us and sure that we were going to do well, and it made us determined that we would. No trouble of ours was too small for him to attend to. When we started route marches, for instance, and our feet were blistered and sore, as they often were at first, you would have thought that they were his own feet, from the trouble he took. He came into our rooms and if anyone had a sore foot, he would kneel down on the floor and look at it as carefully as if he had been a doctor. Then he would prescribe, and the remedies were ready at hand, being borne by the sergeant. There was no affectation about this, no striving after effect. It was simply that he felt that our feet were important and that he knew that we were pretty careless. Nevertheless, there was, in our eyes, something almost religious about this care for our feet. It seemed to have the touch of Christ about it and we loved and honored him the more. We knew that we should lose him, and so it proved. If ever there were a moment of danger, he was on the spot. No one would shirk if he were there. There was not one of us but would gladly have died for him. One day a torpedo fell into the trench and buried some of our chaps. The fellows next to them ran to dig them out. Of course, he was one of the first; and then came another torpedo in the same place. That was the end.

'Somehow he lives, and we who knew him do not forget. We feel his eyes are on us. We still work for that wonderful smile of his. There are not many of the old lot left now, but I think that those who "went West" have seen him. When they got to the other side, I think they were met. Some one said, "Well done, good and faithful servant," and, as they kneeled before that gracious, pierced Figure, I reckon they saw nearby the captain's smile. Anyway, in that faith let me die, if death should come my way, and so I think I shall die content.'

"Donald Hankey, who wrote that, had his wish. He joined his beloved captain when he was killed on the western front October 26, 1916.

"The best that we have survives in such memories. They are worth all the triumphs in politics, business and war. The truest measure of George Washington's greatness is not found in the surrender of Cornwallis, but in the tears of his officers when he gave up the command of the American Army. And Abraham Lincoln will last through the centuries, not as the President of a triumphant Union, but as the man who freed the slaves, and who in one short speech at Gettysburg dedicated this nation for all time to the freedom and brotherhood of man. The noble gentleman who is sitting here on the stage with us will be remembered by our children not on account of his great acts while President, but for the faith and love his gentle, generous kindness have inspired in the heart of every American citizen.

"Is there any man in this room who does not envy the beloved captain? There are few employers in America who would not exchange places with him, who would not willingly trade that memory for a thousand victories in the strikes that have wasted energies. There are few men in the unions who would not surrender to an employer like that. The poorest inheritance of the war will be material gain and the pride that glories in greater wealth and greater power. Its most precious heritage will be the memories that teach the value of work well done in behalf of those in our command. That I believe to be fundamentally the faith of the American engineer, and that I hope may become the practical ideal of every captain of industry. There are many such men in America, and if this war only reveals them to us, we may find some compensation for the lives that we must give.

"We all know men who are, under the right conditions, capable of becoming beloved captains. In their unselfish modesty we sometimes forget the qualities they possess, and the power of expressing to them our understanding is often denied us.

Introduction of the President-Elect

At the conclusion of these remarks, Dr. Hollis introduced to the membership President-Elect Charles T. Main, who was then escorted to the platform. In presenting him to the audience Dr. Hollis said:

"Happily, my opportunity has come tonight in presenting to this company one who in another year will be known to our whole family, as he is already known and understood by a few of us. I could not have hoped for a better fate than to have my year of service buttressed up by two such men as the quiet, unassuming gentleman who preceded me in office, and the next President of The American Society of Mechanical Engineers, Charles T. Main."

In acknowledging the introduction, the President-Elect thanked the members of the Society for conferring upon him such a great honor of leading the Society through a period of great effort and responsibility. He continued:

"During the past year, under the leadership of our beloved captain, many things have been accomplished, but far less than he has wished could have been done. I shall endeavor to maintain and uphold the traditions of our Society and to carry on his good work, but nothing worthy of mention will be accomplished without the support of the whole membership. The work of one man, or the life of one man, is a mere drop in the bucket in the great work which we have to do for the cause of humanity.

"The record of the engineering profession and the work which it has done in the past year is worthy of mention, but I feel that we have hardly begun to bear the full measure of the work which we should do, and I trust that in the next year we may do something which is commensurate with our responsibilities.

"This is not a time to discuss future policies, and it would be impossible to do so owing to the rapidly changing conditions. But there is, however, one ruling and central motive which every member of this Society and every citizen of this country should set up, the concentration of intellect, strength, resources and life, if necessary, to a satisfactory ending of this great war."

Honorary Membership for General Goethals

Following the introduction of Mr. Main was the conferring of Honorary Membership upon Major-General George W. Goethals. In presenting Major-General Goethals Dr. Hollis very happily recalled a little personal incident:

"A few years ago I spent a week on the Isthmus with our newest member. He had as butler a conglomerate wreck of all the Latin races, named Benoit. Whatever happened to the organization of the Canal, Benoit went with the house of the commanding officer. He held his office against all comers by means of a carving knife, and the Colonel could not discharge him. In fact, it lay between the two which would discharge the other. That was the one weakness of the Canal administration. I reveal this now lest you think him more than human.

"We who see him here know his stronger side, and we welcome him as a brother engineer in whose great accomplishment we take a pride. He belongs peculiarly to us, for his talents have been expended on the essentials of modern civilization rather than on the destructive elements of war.

"Honorary membership expresses for the members of our Society the highest gift we can bestow, and we give it to George W: Goethals in recognition of his great work as an engineer and of his fearless execution of duty in carrying the Panama Canal to its completion."

Major-General Goethals, in accepting the honor, said:

"Mr. President, Ladies and Gentlemen: It is generally believed that I built the Panama Canal. That is a mistake. The man who dug it claims to have built it, his successor in office claims to have built it, and I claim to have been one of fifty thousand men who built it. I learned exactly where I came in, in a trip that I took across the Canal in a Panama Railroad train, when a foreman describing the Canal to a visitor led the visitor to understand that he was doing pretty much all of it. The visitor finally turned to him and said, 'What is the old man, as you call him, doing?' The foreman replied, 'Oh, he comes around, and sees us doing it, jollies us a bit, and then goes back and sits in the office and entertains visitors.'

"Those of you who visited the Canal during the construction period must have appreciated the part performed by the mechanical engineers in the machinery that we used for the work, and must have appreciated the mechanical work done in the states in order that we might carry it forward. Those of you who have visited the Canal since its completion, and have seen the satisfactory working of the machinery of the locks, the dredging equipment used in the removal of the slides, and the various other appliances, must have appreciated the work of the mechanical engineers in the designing and construction of that machinery; and, realizing the assistance that they gave in the work, during its constructive period, and appreciating this assistance in its operative period, you may perhaps form some idea of the appreciation I have for the honor that this Society has conferred upon me, by electing me an honorary member, and I want to thank you heartily for this honor."

Spirit of the Annual Meeting

There is one ruling and one central motive which every member of this Society and every citizen of this country should set up, the concentration of intellect, strength, resources and life, if necessary, to a satisfactory ending of this great war.

Mr. Charles T. Main

In the changes that are coming, the engineer can no longer dwell within his technical shell, and he must prepare himself to become a citizen of the world upon whose shoulders great economic and social burdens are placed.

Dr. Ira N. Hollis

If we have not at this moment a clear vision of whither we are tending, now is the time of all times to take stock of ourselves and to redirect our course, whether this course is in conformity with time-honored definitions or not. Change is not necessarily synonymous with progress, but there is no progress without change. No one can doubt that the scientist and the engineer are to be the most important industrial figures of the near future. If we are faithful to our duties we shall be of greater importance politically and socially, but to accomplish this we must broaden our vision and get about our business, which is the industrial organization of our country.

Prof. Dexter S. Kimball

You engineers, all, constitute one of the two professions that are indispensable to the country in the carrying on of the struggle to which the people of the United States are about to devote themselves, yours and the medical profession. . . . the engineer students and the medical students should be required to go on and complete their preparation as engineers and physicians, so that they may become engineers and doctors, and then be gathered into the service of the Government in this war. . . .

Hon. William H. Taft

Address by Ex-President Taft

In introducing Hon. William H. Taft, Ex-President of the United States, who delivered a stirring address on the nation's call to the professional man, published in full in this issue, Dr. Hollis could not resist relating a little personal experience, saying:

"Last year I came to the annual session fresh from a meeting in Worcester, which I attempted to attend with our ex-president, by way of a freight elevator. The elevator went down, not up, and we stuck until we had unloaded a few of the heavy men into a dark cellar. I was there struck with the admirable good nature of this evening's speaker in assisting to tide over the embarrassment of the elevator man, and of his escort to the platform. His wide sympathies cover a vast range, from the administration of a nation's business to the simplest affairs of daily life. He is equally at home with a school boy on the train as with the representative of a great empire. He can say, in the words of Terence, '*Homo sum, et humani a me nil alienum puto*,' a free translation of which: 'I am a man, and nothing that relates to man can be foreign to my heart,' expresses him exactly.

"We welcome him here as one of ourselves, as an agent of mercy in this war, and as the finest example of citizenship in a republic, Mr. William H. Taft."

Before beginning his address, Mr. Taft said: "I find that I have come to the meeting of this Society to hear a good deal that I have to defend myself against. This suggestion that the elevator went down because I was in it is not correct—that

is not the reason — that elevator was in the region where the collegiate institution, that fine school over which your President presides, conducts instruction in the matter of mechanical engineering (loud laughter) — he just had not calculated the load, that was all."

The Engineer and the War

On Wednesday began the professional sessions of the meeting, starting with the all-day war session, at which was given a series of remarkable addresses on the great engineering problems of the war. The opening address by President Hollis on Universal Public Service in Peace and War sounded the keynote. The large audience was responsive to the point of enthusiasm, and reflected the fine spirit of patriotism which was so strongly characteristic of the opening session on the previous evening.

Several of the sessions throughout the convention were inspired by the conditions existing in this time of crisis. In fact, the first meeting, that of the Gage Committee, on Tuesday afternoon, was of this character. Many delegates were in attendance representing departments of the Government, gage manufacturers, manufacturers of munitions in this country and Canada, the Canadian Munitions Board, etc. Questions of the certification of gages and the maintenance of standards in order to promote rapid and accurate manufacturing methods were thoroughly discussed.

One session under the direction of the Sub-Committee on Machine Shop Practice was devoted to the question of Inspection, with particular reference to the manufacture of munitions. Another session dealt with new problems of management incident to the war—namely, the employment of women in the skilled industries, and particularly in machine shops; and the training of crippled soldiers, preparations for which are now being made by the Government, in order that maimed or crippled men returning from the front may continue to be useful, self-supporting elements in society.

Professor Kimball's Address

The character of the whole convention was strikingly summarized by Prof. D. S. Kimball in his address on The Relation of Industrial Management to Engineering, who at the luncheon said that "engineering was broadening to include fields formerly not considered related to the profession, and its ramifications are now so extensive that redefining the aims of the Society would be appropriate."

In speaking of the broadening scope of mechanical engineering, and of engineering in general, Professor Kimball mentioned various subjects which cannot be placed in any definite department, but, nevertheless, must be dealt with by engineers as such. He said he would like to have an inquiry made into the aims and objects of our Society . . . in a statesmanlike manner without reference to persons or groups of persons, but with the sole object of finding out what is best for the Society and what will insure to it an enduring future.

"There will never be a better or more opportune time to consider this subject. Every loyal American is now asking himself what are his duties and responsibilities. Every technical body is facing a reorientation of its purposes and aims. As a nation we are facing a period of self analysis that may result in changing some of our fundamental policies. I am not so sure, for instance, that we shall continue to be a 'refuge for the oppressed of the earth' unless we are quite sure that the aforesaid oppressed are really in pursuit of the liberty and happiness that we all hold so dear. Americanization may indeed be a part of the work of all organized bodies that are interested in the existence of the Republic."

General Sessions

At the Business Meeting, President Hollis's address dealt with the activities of the Society for 1917, and was in the nature of a report. Following it was the presentation by Mr. W. M. McFarland of a bust of Rear-Admiral B. F. Isherwood, late Honorary Member of the Society. Amendments to the Constitution and By-Laws were presented and voted on for issue in letter-ballot, and other business transacted as recounted elsewhere in this number.

Besides these distinctly war sessions there were technical sessions of the usual high order of merit on the Power Plant, Textile Subjects, the Protection of Industrial Workers, and general topics. In fact, there has never been so wide a diversity of subjects discussed at a convention, and subjects of so great importance, as at the meeting just closed.

On Friday the sessions were fittingly brought to a close by the beginning of one of the most important undertakings in the history of the Society. This was the public hearing of the Power Test Committee, attended by official representatives from various engineering societies, college laboratories, governmental departments, railroads and manufacturing firms. The present Power Test Codes of the Society were discussed and suggestions offered for their comprehensive revision.

Entertainment Features

The entertainment features of the convention consisted of a "get-together" meeting for members, at which the members did as they were instructed—forgot the cares of life and joined in general good-fellowship. Past-President John R. Freeman held the interest of the audience by his amusing and enlightening anecdotes of his trip to the Orient last winter. There were other entertaining features provided by the New York Committee. On Thursday evening, Dr. John A. Brashear gave his remarkably fine lecture on the Science of the Beautiful in Commonplace Things, which was followed by a reunion and dance, at which everyone thoroughly enjoyed himself. This lecture was accompanied by many striking demonstrations which appealed strongly to the sense of the beautiful, and which will long be remembered by the large audience of personal friends who greeted "Uncle John." There was also a ladies reception and tea on Wednesday afternoon.

Registration

The total registration was 1965, of which 1115 were members and 850 were guests. This registration exceeded last year's by 88, and was representative of all parts of the country. The national character of the Society, however, was quite as strongly emphasized by the delegates present from the various Local Sections of the Society, of which 19 had representatives in attendance. Important features of the meeting were a Sections' Session, a Sections' luncheon and a Sections' conference.

In this number of The Journal will be found an account of the sessions devoted to subjects relating to the war, including the address by Ex-President Wm. H. Taft; the business transactions; Sections' Sessions, and Entertainment Features. The address by Prof. Kimball and the account of the strictly technical sessions and of the Power Test hearing will be given in the next issue.

ADDRESS OF HON. WM. H. TAFT

Delivered at the Opening Session of the 38th Annual Meeting and Setting Forth to the Professional Men of America What the Country is Fighting For

IT is a great honor and pleasure to be here in this company to take part, if I may so say, in your act of recognition of one of the world-reputed members of the general profession of engineering. Major Goethals, as he was when I first knew him, did build the Panama Canal, whatever he says and whatever he claims. I am able to testify to it, because I was there for eight years and saw him do it, and I know the trouble he had. I know the struggle he had. I know the power of the man in meeting difficulties. I know his tenacity of purpose. I know from its results, not from my professional knowledge, but from its results, his wonderful ability as an engineer in all the fields of engineering, because that task commanded a knowledge of every branch of engineering. I know his power for managing men. I know of his genius of common sense, without which it would have been impossible for him, in face of the difficulties, to discharge the task which he did discharge, and I may say, because an ex-President out of office can say anything—so long as it is truthful—that I am profoundly regretful that the United States and the people of the United States in this great juncture, in this great crisis, have not the benefit of the great ability and great experience of General Goethals. (Loud applause.)

I was a lawyer and I was a Judge, and I was sent to the Philippines. I was sent there—well, I don't know why, but there was more excuse for sending a man there who did not know anything about the subjects with which he was to deal in the Philippine Islands, because there were very few men who did, than there is for putting any man in a position now who does not know a great deal about the subject in respect to which he is to discharge his functions. But, as I say, I went to the Philippines, and while there it fell to my lot to be responsible for some engineering tasks.

We had to do a good deal of engineering in the Philippines, and I came in contact with that very distinguished body of men who have vindicated their existence many a time, and have inspired great confidence in them on the part of the people of the United States—the Engineers of the United States Army (applause), of which General Goethals is a world leader.

And then, when I came here as Secretary of War it fell to my lot to be associated with engineers, civil engineers, who were called in to assist in the determination of a problem that had to be met and solved in the construction of the Canal, and I look back upon my association with men like Alfred Noble; Stearns, of Boston; Freeman, of Providence; Randolph, of Chicago; Parsons, of New York, who is now at the front, and other engineers, with profound satisfaction. (Applause.)

Engineers and Medical Men Indispensable

Now, you engineers, all, constitute one of the two professions that are indispensable to the country in the carrying on of the struggle to which the people of the United States are about to devote themselves, yours and the medical profession; you as the constructors of all the material and all the equipment of which so much is needed now in modern warfare to make effective the work of our boys at the front, and the medical profession to furnish, so far as may be, the aid in restoring to the ranks those whom the fortunes of war disable.

We have a conscription law, which is justified on the ground that it was a selective draft, and we know that under that law those whose services can be most useful to the country in the trenches will be sent over, and those whose services can be most useful to the country in preparing and in saving men and material will be retained in their places at home so that they may not be wasted in the trenches and elsewhere, in which others could do just as good work as they, others who could not discharge the services required of engineers or physicians.

England has, as you know, made mistakes in her great work that she has done. I do not think we have praised England enough. I do not think we realize how much she has really accomplished. But we should profit by the mistakes which England made in allowing her doctors and her medical students, her engineers and her engineer students to go into the ranks and be sacrificed. Because of this, England has reduced the supply of those indispensable persons, so that she is embarrassed, and greatly embarrassed.

Now, my friends, we ought not to make the same mistake. Congress and the Administration should see to it that the medical students and the engineer students should be reserved for the work for which they are particularly fitted; that the engineer students and the medical students should be required to go on and complete their preparation as engineers and physicians, so that they may become engineers and doctors, and then be gathered into the service of the Government in this war to help the Government in those places in which, as I say, they are indispensable. (Applause.)

Now, there has been a difficulty—there seems to have been a fear that temporary exemptions would mean favoritism, and Congress and the Administration have not been as prudent as they should have been with reference to these invaluable agencies which we should make as strong and as full as possible. Congress is now in session, and therefore Congress ought to take steps to give power, if power is lacking, to the Secretary of War, to the Secretary of the Navy, the Secretary of War particularly, to deal with embryo engineers and embryo medical students, so that we may have as many engineers and doctors as we can possibly have, because we shall need them all.

Of course, other professions are helping too, lawyers and ministers, we are likely to have enough of them (laughter)—and I do not see why exemption should be claimed for them—and being a lawyer I can say so. I do not mean to say that lawyers are not patriotic, that lawyers are not being called upon now for gratuitous services which they are rendering in connection with this draft, but I do say that as a permanent thing their services are not likely directly to promote the winning of a battle like Cambrai, whereas the engineers may help; and it thrills one's American heart to know that the members of your profession, now tonight, are engaged in exposing themselves and fighting for the great cause, in which this Republic is so much interested, and to which the greater part of the world is so devoted.

MUST TALK ABOUT THE WAR

I was not quite sure what I ought to talk about when I came here. What I have said up to this point, like the President's few remarks, has not been my speech. One cannot come before an intelligent audience like this and fail to talk about the war. I have talked about the war a good deal in various parts of the country and I have been impressed with the feeling that the war could be talked about a good deal more about the country, throughout the country, to the people of the country, with very great advantage. There are so many who are doubtful they are for the Government and they are for the war, but they are walking interrogation marks as to whether we did not make a mistake here, or did not make a mistake there, or whether we are fully and rightfully in the war, that I think an evangel ought to be preached on the subject to demonstrate that we are rightfully in the war, that we never have done anything that was not justified, and that the cause now presented to us is so righteous that if we are the people we claim to be we must win it if it costs the last man and the last dollar that we have. (Prolonged applause.)

You meet men who are now, after we have decided to go into the war, and after we are in it, who are now "judicially-minded"—that is to say, they do not say they are neutral, but they are judicially-minded. While I am in favor of being judicially-minded, I am not in favor of masquerading under a judicial mind a lack of that fine edge of loyal patriotism that we need to carry this country through the war. (Applause.) I am opposed to apathy; I am in favor of team work, and of knowing why we are in, and what we are going to do, and in favor of being determined to do it. (Applause.)

GERMANY'S BREACHES OF INTERNATIONAL LAW

You will find this judicially-minded person suggest that we were unneutral during the three years that we were not in the war, because we furnished ammunition and other supplies to the Allies. Well, we had a right to do that, under international law. Germany herself had agreed to that rule of international law with respect to the power and duties of neutrals—not that neutral governments could furnish such supplies, but that neutral governments could permit their citizens to do so, the citizens taking the risk of confiscation of those articles as contraband if found upon the high seas. And there were those who sympathized with Germany after the German commercial marine had been driven from the seas, and they said it was unneutral for us to furnish one side.

The fortune of war was not our fault. The President was right in insisting that we should stand by the rule of international law in that regard, because if by our acquiescence the rule of international law were to be changed, requiring every neutral government to suppress its citizens from carrying on such a trade, it would only make overwhelming the advantages of a military nation that devoted itself, as Germany did for fifty years, to getting ready for this war, and which has piled up the ammunition and supplies needed to carry her through years of war. We, if subjected to a war-[illegible], would never be ready. We would always be unprepared, and as a consequence, when forced into war, we would have to look about to prepare suddenly, and then find denied to us the right to get our material and supplies from the citizens of neutral nations, under the new rule suggested. Therefore, it would have been the wildest lunacy for us to consent to a change of international law in that regard, and the merits were wholly with the President in taking that position.

But, notwithstanding the fact that we pursued the path of neutrality as laid down by the law, Germany sank an English commercial liner having three thousand persons on board, and sent to their death 114 American citizens by the murderous torpedo which her submarine hurled at this vessel. Then for a year we continued a discussion, arising from Germany's unfounded claim that the vessel was armed; then she sank another vessel under similar circumstances; then we said that we would sever our relations with Germany; then she said that she would discontinue that method of warfare until further notice; then on the 31st of January last Germany notified us, as she notified the world, that she intended to resume the ruthless submarine warfare; then shortly afterwards we severed our diplomatic relations with Germany; then she sank four or five American vessels, returning to this country in ballast, and sent to their death some twenty-five or thirty American sailors; and then we declared that a state of war existed.

OUR DUTY AS A GOVERNMENT

Now, my friends, is there anything else that we could do but that? That is where your judicially-minded person would come in. The answer to my question depends, first, on the proposition of what were our rights, and what were the rights of our citizens? and secondly, what was our duty as a Government with respect to those rights? International law is indefinite in certain respects, but it is as definite as the law of promissory notes with reference to the rule of the capture of commercial vessels at sea. A belligerent may capture the commercial vessel of its enemy and sink that vessel. It may capture, under certain circumstances, a neutral vessel, violating a blockade, and possibly may sink it, but an incontestible rule for a hundred years has been that that right of capture and right of destruction is subject to one limitation, namely, that the ship's company of the captured vessel shall always be put in a place of safety before the vessel is sunk.

Admiral Semmes in the Civil War sank perhaps four hundred or five hundred vessels of the United States commercial marine, but he prided himself that in all that destruction not one single human life was lost. He was an international lawyer of repute; he was also a naval commander, and his course in that regard is the strongest evidence of what international law is on that point. Therefore, Germany violated the rights of those citizens whom she exposed to death and whom she sent to death. When a man kills another deliberately, without right, it is murder, and there is no other word nor any other term in international law that can be applied to a case where a nation kills men and women and children without right. (Applause.)

GERMANY'S WARNING OF MURDER

Ah, but it is said these people had notice. That distinguished and eminent Christian statesman, Count von Bernstorff, had whispered over the telephone and had intimated very enigmatically that any one who went aboard the Lusitania would run the risk of being torpedoed, and it is stated that those who went down in ships sunk afterward knew that Germany was on the sea with these murderous instruments. Well, that is a fine plea. Suppose a man in New York should warn a neighbor that he could not go down into the street upon which his house abutted, because if he did he would kill

him; and suppose this man who was warned was a courageous American citizen, who knew what his rights were and he went down into the street, and the threatener did kill him. Suppose that man was indicted and haled into court and called upon to plead, and he pleaded "Not guilty" on the ground that he had notified this man that if he would come down into the street he would kill him, and therefore he was not guilty because the man himself was guilty of contributory negligence in running into a bullet whose presence he ought to have anticipated on the street. (Applause.)

But Senator La Follette says—(hisses on the part of some persons in the audience), oh, don't hiss, it never helps to call names, no matter how poor an opinion you have of a man, it does not help the argument—but Senator La Follette says it is true they had the right to be where they were, but those were technical rights. It is too bad when a senator in Congress, sworn to obey the Constitution, should regard the right of those poor victims on board the Lusitania to life and the right to protection against the invasion of a murderous nation as a technical right.

What Was Our Duty?

We will now assume, therefore, that this was murder of our citizens. What was our duty? The Constitution as interpreted by the Supreme Court, indeed our general knowledge of government, would teach us that while we owe service, military and civil, to the Government, the Government owes us as a primary consideration, protection. Government is nothing but a partnership in which we are all members, and we all agree to contribute to the objects of a partnership by service; and then the partnership is to help us in enabling us to enjoy our rights. Therefore, when these citizens were actually deprived of their rights, why, it is very plain that it was the business of the Government to call for reparation in respect to those whose rights had been taken away, and security and an announcement of the policy which would prevent subsequent interference with similar rights of our citizens. Otherwise, if not, then we ought to go out of the government business, because that is the object of government.

Now, Germany announced that she not only justified what she had done, but intended to continue to murder our citizens on the high seas. Our citizens are entitled to the protection of the Government at home and on the high seas, and abroad. Abroad there is some qualification, because they voluntarily submit to another jurisdiction, but on the high seas, on an American vessel, and under an American flag, on that great road of the nations, they are just as much within the jurisdiction and within the protection of the Government at home as if they stood on the shores of New York, or Massachusetts, or New Jersey, and an invasion of their rights on the high seas by a foreign government is just as much an invasion as if Germany had landed a Uhlan regiment on our shores and shot into the homes of American citizens and killed them.

Therefore, if we were to continue business as a government, there was nothing else for us to do—Germany did not leave it open—except to measure swords with her in protection of those rights. If this act had been committed by Venezuela or Costa Rica, if either of those countries had sunk an American ship with a loss of one hundred lives, the President would have promptly sent a message demanding reparation and security against further invasion, and might have sent a warship down to convey the message, just by way of suggestion, and every man, woman and child, Senator La Follette, and every pacifist, would have said, "Well done." Well, now, what is the difference between that case and the one we are considering? There is not any in principle, but there is this real difference, that Germany is the greatest military power in the world, and Venezuela is not, and therefore we are very urgently and strongly in favor of the protection of the rights of American citizens when invaded by a foreign country, provided the country is little enough, but when it is a great power—the greatest military power—then the rights are "technical." (Applause.)

Oh, my friends, there was not anything for us to do except to declare war, and a pacifist or anyone else who says otherwise or intimates otherwise, does not understand. The President has set a precedent by calling them stupid, and, after such an authority, I am willing to say I agree.

Now that brought us into the war, but when we got into the war we found what possibly we ought to have known before—some did know—that the particular cause which brought us in was only a phase of the far greater cause which the Allies were engaged in fighting. We found ourselves in the beginning ranged with democracies against autocracies. I know that our judically-minded friend will suggest that England is a monarchy and so is Italy. Yes, that is true, but a democracy is a country in which the people rule, in which the policies of the government are determined by the popular will. The proof of the pudding is in the eating of it. Any one who knows anything about England and Italy cannot say otherwise than that the people rule in these countries, and where that is the case they are democracies. Where that is the case, the question of kings is only a question of taste. As a matter of fact, the King of Italy and the King of Great Britain have not any more to do in determining acute questions of the policies of their respective countries than an ex-President of the United States has. (Applause.)

The Meaning of Democracy

Now, the President has said that we are fighting this war to make the world safe for democracy. That is a truly exact statement. But it has been misconstrued. It does not mean that we are to force democracy on other countries, that we claim to have a patent for our form of government that we are going to drive down the throats of other people. That is not what it means. It only means that the power of a people with a military and foreign policy such as that of the Imperial German Empire, is dangerous to the continued and safe existence of smaller and less powerful countries that desire to have democracies and to work out the happiness of their people through that kind of government. That is what it means.

We Must Understand German Character

We cannot understand the issues at stake without understanding the character of the German people. We cannot understand their character without following their training in the last fifty or sixty years. We all have known Germans. We have liked them. When in Germany we have enjoyed seeing them. They are a kindly people; at least they were some years ago when I visited Germany. They are a kindly people, who love their homes, they love their families, they love music and they love poetry, of which they have some of the greatest exponents in the world. They conform to authority with a kind of pleasure. They are an intellectual people, they are an earnest people, a little lacking in a sense of humor, but a great people, people capable of great effort.

The truth is, while I have a profound admiration for the

English people and the history of England, because having been educated as a lawyer I believe she laid the foundations of true constitutional liberty, nevertheless, I am bound to say that when I went to Europe and traveled in Europe, I would a great deal rather be closed up in a railway carriage with a German than with an Englishman; because the Englishman—I mean the regular Englishman—was constantly engaged in an affirmative effort to convince me that he did not know I was in the carriage, whereas the German was always courteous and friendly and anxious to engage in conversation.

Some Glances at German History

The Germans for a long time were divided into twenty-eight different States, Austria the greatest of them, Prussia the next, and twenty-six others, and every one who longed for an improvement in the world, and an improvement among the Germans, wished for unity among them. There were liberty-loving Germans, and in '48 they rebelled against the Divine Right of Kings, and they had revolutions. They were not successful. They did get a constitutional monarchy for a little while in Prussia, and offered the crown to Frederick William, the great-uncle of the present Emperor, and he said he would not take it, because he got it from God, and did not purpose to take it back again out of the mud, showing that the Divine Right of Kings came honestly down that line to its present exponent.

A large number of these liberty-loving Germans were driven out of Germany and came to this country, and made one of the most valuable elements of our citizenship here (applause), and when the Civil War came on, loving liberty as they did and hating slavery, they went into the war, enlisted in great numbers, and on every battlefield in that war the blood of our German citizens was shed.

Their descendants and others who have come here since have continued to make a valuable part of our citizenship, and during these three years when we were neutral they have naturally, because of their pride in the success and prosperity of their brethren at home, had a sympathy with Germany and listened to the arguments in her behalf which have been put forth in this war. And now the war between America and Germany has come on, and their allegiance requires them to be loyal, and they are put in a sad position, and one in respect to which we should be considerate of them. But they are loyal, they have enlisted, they have gone into the draft, and contributed to the great patriotic funds; and while they are not vociferous—we could hardly expect them to be so—that they are going to be loyal I have not the slightest doubt (applause), and one of the things we ought to be most thankful for is that very thing. The reason why Germany treated us as she did was because she counted on dissension among our people, growing out of the disloyalty of that very element, and she has been disappointed in that regard as she has been disappointed in so many of those instances where she has attempted to read the motives of other people.

Instead of founding a constitutional monarchy, with representative institutions, and bringing about unity, as those leaders of German thought, Carl Schurz and others hoped for, there came into the history of Germany a very different individual, Prince von Bismarck, who was the Premier of Prussia in 1862. His theory was that he would conquer and unite the German nation by blood and iron, and he developed the army, always a well-controlled body in Prussia, and he made the nation into an army, and an army into the nation, and then he planned the wars upon which he founded the unity of Germany. He became involved in a quarrel with Denmark, and induced Austria to go in with him, and took away Schleswig-Holstein from Denmark; and then when he got it, he found it was so easy that he annexed it forcibly to Prussia; and when Austria asked, in a diplomatic way, just what there had been in that war for her, he said there was not anything. And then he got into war with Austria, as he had intended, and in six weeks he wiped her off the map of Germany. Then in that war he annexed forcibly Hanover and Frankfort, and made an offensive and defensive alliance with Württemberg, and Baden, and several other German countries; and then he sat down to wait until that fakir, Napoleon III, in his pirouetting, would bring about an appearance of a war of aggression against Germany, which was exactly what Bismarck was waiting for, and he only had to wait four years for that; and if you will read his memoirs you will see how he brought that about. You will be interested in reading, I am sure, that interview between himself and von Roon and von Moltke. They received a telegram from the Emperor outlining an interview between him and Beneditti, Napoleon's Ambassador, and they were thrown into gloom, because the interview was one which seemed so pacific to them that they thought its publication would prevent war; and Bismarck sat down and, without changing the body of the message, changed a few words in it and published it; and then von Moltke said—"Now we will have war." He said—"That telegram, when it came, sounded like a parley. As you have changed it, it sounds like the rattle of a drum." This was stated by Bismarck himself. So, true to his plan, Napoleon declared war, and then, in a short time, Bismarck defeated France and took Alsace-Lorraine and an indemnity of a billion dollars, which the Germans put into the army, and Bismarck crowned a Prussian King Emperor of Germany at Versailles, and he went back to Berlin and sat down as the head of the Empire to digest the pieces of territory he had bitten off in the last three wars.

Bismarck's Seeds of Kultur

He was not in favor of world dominion. He wanted to raise Germany to a great power in Europe, and he succeeded. He made fun of the ideal of world dominion, but there was held out to the German people the idea that all the rest of the world would try to get back from them this territory which had been taken, and therefore they must defend themselves, and so they went on and provided greater and greater armies.

They also adopted in their wonderful way, as you gentlemen of science know, the principles of science to the manufacture of everything, and to every field of industry and business. They introduced a system which they called Kultur, and which brought about a prosperity in competition with the world that attracted the admiration of the world. Their population increased and pressed upon their borders, and with their marvelous successes in the three wars, with their wonderful administration and the demonstration of their efficiency in their prosperity, and with their increase of population, they acquired megalomania, and they learned to think that they were supermen. They believed they had invented Kultur, and it was their duty to spread it over the world and enlarge their borders and conquer the world for the purpose of spreading that Kultur.

And they soon, by reason of their elevation as a people, associated themselves with God. They regarded themselves as the agents of God. They are a people of an inexorable logic. If they begin with a false premise, as they often do, their confidence in logic is such that they wipe out any fact

that is inconsistent with the conclusion reached by that logic. You remember the story of the old German who was in the California gold diggings and met a man out there whom he had seen only recently in New York; and anxious to find out how he had gotten there he asked: "You came the plains across?" The man replied, "No." "Then you have come the Isthmus over?" "No." "Oh, then you come the Straits of Magellan through?" "No." "Oh, I see, you were seasick coming the Horn around?" The man replied, "No," and then the German's eyes opened and he looked at the man for a minute and he said: "Well, then, you have not arrived!" (Laughter and applause.)

Having established that Kultur was necessary for the world, and that they had invented it, they believed that they were the people to spread it; and then, with that inexorable logic, all of these other conclusions followed. The State, the German State, was to spread Kultur. It was to do God's work. Therefore, every consideration must yield to the doing of that work. The State was above everything. The State, engaged in this work, could do no wrong. Therefore, these considerations of honor and decency, and the performance of obligation, could play no part. International morality was eliminated. The only sin of a State was weakness; its virtue was power. And that doctrine, or its elements, the idea that Germany was over all, was preached in the schools, in the academies, in the universities, by the great lecturers, by the military writers; and the conviction grew with the people, first, that they must protect and defend themselves and give everything to the Army necessary to accomplish that, and, secondly, that they must base their State on force and maintain that force in order that they should spread Kultur to the world by domination and conquest. They eliminated, as I say, international morality.

Now, that is the nation and that is the people that we are engaged in fighting. They are obsessed as with insanity, otherwise you cannot explain what you see and read and know. "Why is it," you ask, "we did not know this before we got into the war?" Well, we read excerpts from the lectures and military writings, but we have cranks of our own—I need not mention them—but certainly we do not want to be held responsible for their writings and their statements and their actions, and we assumed that these people, thus speaking among the Germans, belonged to that necessary and conspicuous, but we hope with us unimportant, element. But it was not so in the case of Germany, and you can read now the books that have been prepared impartially showing these sermons and lectures, and showing that these lectures spoke for all the people. Consider, for a moment, that there was a writer who in one of his writings incorporated a prayer like this:

> Oh, Thou, who presides over all, up above, high in the skies, up above the Cherubim and Seraphim—and the Zeppelins—

Now, that association, if it did not shock your feelings as irreverent, would suggest a humorous view; but to the German mind, with the idea of what the zeppelin was do to in spreading Kultur, it was the agency of God; the association between the cherubim and seraphim, which are supposed to be God's agents, with the zeppelins, was entirely proper. They preached sermons on the German God.

We Are Fighting the German People

It is the people of Germany we are fighting, with the characteristic they have of subordination to the authority of the Prussian military regime and the Kaiser, and we must not assume they are compelled against their will to do this fighting. They have made too many heroic sacrifices in loyalty to this false idea, and in loyalty to the leadership of the Kaiser, and therefore what the President says must not be misconstrued. What we are trying to do is to separate the people of Germany from the rulers of Germany, but the only way we can separate them from their rulers is by hitting them on the head with a club so that the psychology of the situation will be brought home to them. (Great and prolonged applause.)

If you look for proof of this position of Germany with reference to the abolition of international morality you can find it in their method of warfare. I do not think it necessary to go into a detail recital of the awful atrocities that have been proven before you can arrive at a general conclusion as to their violation of every rule of warfare. They bombarded unfortified towns, an act which is forbidden by international law, and the men who bombarded these unfortified towns on the east Coast of England were rewarded by being decorated with the Iron Cross.

The Hague Conference provided certain rules with respect to the carrying on of war by means of aircraft, one of which was that belligerents were not to drop explosives from aircrafts on undefended towns; and the Germans promptly sent their zeppelins, that were assembled for the purpose of carrying on war, and to which they turned for the purpose of carrying on the war, and they sent these zeppelins to England and slaughtered innocent non-combatants. Of the thousands of victims of the zeppelin raids, possibly not more than fifty soldiers and sailors were hit, and only one or two arsenals, but the great body of the victims is composed of women and children, and old men. The men who navigated the zeppelins in these air raids were also rewarded with Iron Crosses.

The Path of Kultur

When the Germans entered Belgium they violated their treaties through which they had given their plighted faith for sixty years with the other nations. You would think, when they went into Belgium, under those circumstances, they would treat the people with some consideration, even in spite of their obsession. Did they? No. What they did was to take a district in Belgium and direct their soldiers to pursue the policy of Schrecklichkeit, that is, to stand up against a wall the leading citizens and shoot them, as well as the women and children. You ask for proof? Well, read the report of Lord Bryce. He is a lawyer, an able lawyer, and an historian, and he was on the Committee with other lawyers and Judges, and they took the evidence and dissected it and analyzed it. They rejected all the evidence as to the sporadic brutalities by soldiery which you encounter in every war, and took only the evidence of cases that could not have been committed except by the order of officers, and they showed that this was part of the military policy of Germany in terrorizing the rest of the innocent Belgians by such cruel atrocities in respect to the families of this particular little district.

But the worst thing they have done has been with respect to Armenia. When England brought over the Indian troops to help that small regular army of hers, and they came and made good soldiers, showing they had been well treated, the Germans held up their hands in holy horror and said, "They are sending Mohammedans to fight Christians," all the time having that eminently Christian Monarch, the Sultan of

Turkey, in alliance with them. And after the alliance was secure, then Turkey proceeded to carry out a purpose that she had partially attempted to carry out years before in ridding herself of Armenian Christians in her Empire. She proceeded, with Germany looking on, and with officers of the German Army at hand, through her regular soldiery and her irregular soldiery, to murder eight hundred thousand Armenians because they were Christians. Now, that is an evidence of the false philosophy, the horrid philosophy, that there is no international morality, and that nothing should stand in the way of military success and the advance of the State in the spread of kultur.

That is the kind of enemy we have to fight. That is the psychological state of the German people, and the only way in which we can change it, as I say, is by defeating them. If we defeat them, then they will appreciate the falseness of a philosophy which can only be justified by victory, and then when they are defeated, as we must defeat them, then they will relegate the Kaiser—it will not need any action on our part—they will relegate the Kaiser and the Prussian military regime to the place where they ought to go. (Applause.)

It is a very satisfactory thing to see that the sin of the Germans in this regard has found them out. When the war began, good Christians hesitated about believing in a good God, when they saw that so many innocent men could be hurled into a vortex of destruction, agony, suffering and death like this. Now the thing is cleared away, and what we see is that the world has been suffering from a cancer of militarism, and Germany has been responsible for it, and she has led the world on to these great armies, and on her hands is the blood of this awful war—this war with fifteen or twenty times the number of men engaged in it, and with an equally increased amount of suffering and agony, compared with any other war—with 40,000,000 men engaged, 7,000,000 men dead, 6,000,000 men in the hospitals, and 6,000,000 men in prison camps. That is due to Germany. The causes cannot be cut out but by suffering. God works by inexorable laws, and the penalty of sin must be paid.

This is a German war of aggression as any schoolboy can now see. The White Paper did not show any communications between Germany and Austria during that anxious time, and they have never been disclosed, but we know now that Russia was not prepared, and England not any more prepared than we are today, and France was very lacking in her preparation, and yet we are to believe that these three countries conspired to attack Germany who was ready to the last cannon and the last reservist. Why, that is enough to make a horse laugh. It is true that Germany did not advise the killing of the Crown Prince and his Consort. That is not the way Germany has begun her wars. She gets ready. She plans a war. She gets ready, and then she waits for the opportunity so that it shall seem to be a war of aggression by other powers. That is true in every war she has waged since Prussia has been in power.

Germany's Woeful Blunders

So to go back to this sin of Germany finding her out. She has been perfect in military preparation; she has been perfect in military strategy, but where has she made her blunders? She has made her blunders, and her great blunders, in misreading other peoples, in her diplomacy, and she has made these blunders because she has eliminated from her own soul considerations of morality and motives of good, motives of service and allegiance and unselfishness, and therefore she has eliminated those from her judgment when she goes to judge of what other people will do. So she made a mistake about Great Britain, and her conscience in respect to Belgium. She made a mistake as to the British possessions—I mean those independent dominions—she said, "The tie which binds the dominions to the mother country is very light. There is no reason why they should go in, there is nothing in it for them," and she was indignant and exasperated when she found that her judgment in that regard was wrong. That is because she could not appreciate the filial relation between those countries and Great Britain. She could not appreciate the daughter's loyalty to her mother that had protected her. Is there anything more noble in this world war than the way in which Canada and Australia have responded to the call of the mother country? Canada has sent 420,000 men, and Australia 400,000 men, Australia having a population of five millions and Canada six or seven millions. In proportion, we would have to send an army of seven millions. And then France. Germany said France was decadent, permeated with socialism, no patriotism, and deeply affected with frivolity. France was not prepared, but she rallied her legions, and is it not inspiring to think of the fight that she made, knowing that the German military staff was attempting to crush France first, and she stood up, and with that thin line of the British regular Army, she hurled back the German hordes at the Marne and saved the world. (Great applause.)

The biggest mistake she has made has been with respect to this country. I remember some of the things the papers said—they said we were a tangoing nation. They said we were too fat to go into the trenches. They had a contempt for us because we had not prepared for war. They assumed our citizenship of German origin would prevent the war, and political considerations would divide the people in that regard. They were also obsessed with the idea that they could end the war with this murderous weapon, this weapon they could not use except by accompanying its use with the murder of neutral people. So they went in.

Now, ten, fifteen or twenty years hence, when our grandchildren go to their fathers, after having read a history of this war, they will say—"Papa, why in the name of common sense did Germany force the United States into this war?" And papa will have a hard time to tell, unless he goes into all of the circumstances and treats the subject from a psychological standpoint, because the boy will say, any child would say—"Why they had been fighting this war for three years, exhausting as no other war has been before, so that they were all not exhausted, but nearly so, and at that time they deliberately forced into the war against them that gigantic young nation that could furnish what is absolutely necessary, and what must determine victory in the war, more food, more money, more fighting men than any nation in the world."

Now, that is what they have done, and nothing can explain it except the obsession that I have referred to—their failure to see things in other people, because they have eliminated from their own consideration those moral motives. Now what are we going to do about it? I have said, potentially, we are the greatest power in the world. We are a potential military power, and we have got to make that thing which is potential actual, and that is no mean job. We have before us a war of two, three or four years. We have got to raise an army of five million or seven million, or possibly more. It is man-power that is going to win this war. Russia has become a pulpy mass, and it has got to work out its own salvation. There is one feature about that situation, and that is that the

Germans will not know any more about what is going to happen in Russia than we do, but it is going to enable the Germans to bring back, doubtless, many of her divisions to the Western front; and we must fight the war out on the Western front, and it may be that the Western front will reach from the North Sea to the Adriatic. We have got to furnish to our Allies not only food, not only money, but we have got to furnish them the man-power that will give a predominance that will win this war. We have got to wear them out, it may be by attrition, as Grant wore Lee out, but we have got to do it, because civilization depends upon it, because our own independence depends upon it. The war is not in our souls yet, not as it will be when our boys are shot down, and when we consult the casualty lists to see whether those dear to us have suffered. One of the great satisfactions is that when we are in it, when we meet disaster, as we are going to meet disaster, and we find there have been blunders, as there will be blunders—but from these blunders and from these disasters the American people are so constituted, with their inherited traits, that those disasters and blunders and defeats and humiliations will only make us stronger to carry out the struggle that is essential to liberty and Christian civilization. (Loud applause.)

KEYNOTE SESSION

An All-Day Meeting on the Service of the Engineer to the Public in Times of Crises, with a Series of Addresses on Great Engineering Problems of the War

THE topic now uppermost in the minds of everyone, and engineers in particular—the war—served as the basis for an all-day session in the Auditorium on Wednesday, December 5, which attracted large and deeply attentive audiences both in the morning and afternoon.

Promptly at the opening hour, President Hollis, after a few preliminary remarks, called Vice-President Charles H. Benjamin to the chair and then launched into his stirring opening address on Universal Public Service in Peace and War, in which he sounded the keynote of the day's discussions in his illuminating development of the thesis that training for citizenship is the safeguard of democracy, and emphasized the relations and duties of the engineer to the state in the present great emergency. Four additional addresses were delivered before the luncheon intermission, as follows:

The Engineering Societies in the National Defense, Gano Dunn.
Special Education in Time of War, Dr. Charles S. Howe.
Engineering Research, C. E. Skinner.
The Agricultural Problem, L. H. Bailey.

The afternoon session began promptly at 2 p. m., Vice-President Charles T. Plunkett officiating as chairman on the invitation of President Hollis. Five addresses were delivered at this session, namely:

The Fuel Problem, Prof. L. P. Breckenridge.
Motor Transportation, William P. Kennedy.
Army Transportation, Major L. B. Moody.
The Aircraft Problem, Prof. W. F. Durand.
The Solution of the Cantonment Construction Problem, Leonard Metcalf.

The texts of these ten addresses immediately follow.

UNIVERSAL PUBLIC SERVICE IN PEACE AND WAR

By DR. IRA N. HOLLIS, WORCESTER, MASS.

OUR profession has long been classed as one concerned only with the application of science. It covers a very wide range reaching, on the one hand, from invention and construction that affect the whole history of this race, on the other hand, to the little things that add only to convenience and comfort in our daily lives. Transportation, for instance, in opening to every nation the products of all others, and in permitting the ready ebb and flow of travel, has had a profound influence upon industry and upon the world outlook of men. Our thoughts have sprung beyond national barriers. This war is a temporary setback, but we shall come out of it stronger than ever for human brotherhood.

In the changes that are coming, the engineer can no longer dwell within his technical shell and he must prepare himself to become a citizen of the world upon whose shoulders great economic and social burdens are placed. He must study history, the science of government, and the problems of labor, that he may grow to the maximum of his possibilities. His training has fitted him for anything, providing he does not stop all the humanities after leaving college. His work will be better done for conscientious performance of civic duties and, if thereby he is drawn away from technicalities, his education will have justified itself. At this time there is nothing more important to him than a clarification of his thoughts on government and public service. He cannot afford to remain outside the life of the nation, and he must exert himself to do and to know. For that reason, it is a happy thought on the part of the Meetings Committee to set apart this day for public questions. The first thing in any discussion is a courageous look into our shortcomings as a nation. We have the faults of youth, not because our form of government is inferior, but because it is superior. We impose only as much government on the individual as is absolutely necessary to hold society together.

The great difference between the Allies and the Central Powers lies in the attitude of the individual toward the state. Two conceptions are found in modern times; one springing out of Rousseau's revolutionary doctrine that government is derived from the consent of the governed, and the other from the ancient divine right, under which the governed derive their privileges from the consent of a ruling class, or of a crowned head.

In the first case, society regulates itself and the state is wholly a possession of individual citizens. In the second case, society is regulated by those set above, and the individual belongs entirely to the state, in whose service anything may become justified. These two ideas lead to characteristic failure when carried to extremes: as, for instance, in a democracy, liberty unchecked by public opinion is likely to become license, and freedom may mean simply the power to do as the individual pleases, without reference to the common welfare; equality would be nothing but a dead level of property under this theory that would render democracy the most oppressive socialism. In an autocracy, the individual, as the

property of the state, may become a murderer, a liar, a thief, and the lowest of conspirators without loss of station, provided his deviltry is committed at the behest of the ruling power. Secret diplomacy against the well being of other states will always flourish under a military autocracy.

In the first of these cases you have the destruction of individual conscience as related to the state; in the other, the complete breakdown of national morality in relation to the world. We have these two extremes at the present time side by side in Europe: Prussia with the unbridled license of the ruling classes to do evil, that their good may spring from it, and Russia with a complete collapse of state morality in the hands of ignorant socialism.

Training for Public Office

Extremes in government are always wrong, and wise men have studied for ages how to check that tendency. It is perhaps the most important problem that we have in our own country, where every individual can express his views freely without fear of being arrested for adverse criticism against a dynasty. Every public officer is a public possession, and can be dissected without any hindrance on the part of the law. This implies for success in government a self-control that comes only with training, and the American people may well pause to think more seriously about training for public office and for citizenship in a democracy. We have had very loose views on this subject ever since the formation of the Republic. Anyone may be put into any office on the principle that American common-sense will somehow muddle through. Hence this subject is more than timely. It is the psychological moment when all people, especially the engineers, should strike a good blow toward the education of men and women for service under the state, and for that kind of self-control and sacrifice that produces efficiency in a republic.

As a matter of fact, this whole subject is of vastly greater importance at this session of The American Society of Mechanical Engineers than any technical or professional paper could possibly be. While a single invention may often change the whole course of human history, the freedom of man for his own development is so dependent upon his training, or education, that we as engineers ought now to turn our minds entirely away from technicalities of science to the fundamental rules upon which all society must be based. We are citizens first, and engineers afterwards, and while we know that the externals of civilization have only kept pace with the progress of our profession, we know also that the spiritual side of man's nature is a development of the geologic ages. Short periods of history disclose relatively little change. During nineteen hundred years of great material growth, humanity as a whole has not taken a single step toward the realization of human brotherhood, except, perhaps, in the surrender of legal ownership in slaves. The mechanic who works for us lives in a style that a monarch of the middle ages might have envied. A traveler four thousand years ago coming out from Egypt would have written a book about his adventures in crossing the little arm of the Mediterranean, called in ancient times the Syrian Sea. But we moderns have many in America who consider a journey around the world only an event worthy of an evening's conversation with a few friends. Through engineering we know the world and every corner of it, as our grandfathers could not have known it. We know how nation has come to be dependent upon nation. Yet ethically we are still as blind as the money changers who were driven from the temple by Jesus Christ, and we are fighting the most horrible war in all history.

Engineer's Task in War

Every war has its roots deep down in the history of the race, and it is often very difficult to trace the causes. In our Spanish War the immediate cause, or the immediate event, that brought about the war, was the sinking of the *Maine* in Havana Harbor under circumstances that seemed to put the responsibility on the Spaniards. The real basis of the war dated back for generations, and was only the result of many struggles against the autocratic power of a nation exploiting American colonies for its own benefit, without any reference to the good of those who were exploited. This war too is the result of great forces that seem always to have existed. It is made more horrible by the inventions that began with James Watt's improvement of the steam engine into a workable machine. While it is not caused by the work of the engineer, it is essentially an engineer's war, in the respect that it uses all of his talent toward making the war more terrible. It is the culmination of the century of invention that followed Watt, and represents a struggle between those who have deliberately conspired to make use of all human resources and invention for securing dominion over the world, and those who believe that man advances in true happiness under individual freedom far better than under the direction of autocracy.

It is our task as engineers to assist in making the world safe against the forces that we have unloosened, so that the century may not close with a total failure of the civilization of Christian races. It is we who have developed the applications of science, and it is we who are using it to destroy one another, forced into the struggle by the rulers of a nation that knows no right except might, and no mercy except that which is taught them by the sword. Our great problem will be, not how to develop further, but how to tame what we have. Unless some conscience is aroused that science is not to be used against man, but for him, then it will never be safe for this world. It will always be an explosive ready to go off and destroy. The poisoning of wells is nothing beside the reversal of preventive medicine into a destructive agency. Every practical invention can be turned into evil for destroying the white races in favor of the yellow and black men, who have no science.

Best Training is Educated Conscience

We as engineers must take our share in quickening the conscience of the American people toward the danger of unlimited, unchecked forces, and in preaching night and day the importance of an educated conscience. That is, after all, the most effective training for public service, and the best antidote against the unholy advance of scientific brutality.

It is a curious thing that James Watt should have been prevented from practising a trade that he had learned in London by the trade guilds of Glasgow. The potent influence over his life and over human history sprang out of his having been driven to take refuge in a university as mathematical instrument maker, where he was called upon to do all kinds of odd jobs in connection with a physical laboratory. By a strange irony he improved the steam engine and thereby let loose the forces of labor-saving against the trade unions, thus creating problems infinitely more difficult than anything connected with labor a century and a half ago.

In what respect is democracy to be preferred to an autocracy which safeguards the material welfare of its citizens, and provides through state regulation for their comfort? That question is an important one before the American people, and we

should study it in order to understand and buttress our own institutions. Our education has taught us that there is only one answer, and we believe that science is safe only in a democracy such as ours.

Efficiency has come to mean something new to us, and by it we can make an adequate comparison between the two forms of government, but we must take efficiency in the most comprehensive sense of the word. It is nothing to mankind if by reducing the labor required to produce the necessities of life, it simply enables a country to support a larger population. The thing worth while is righteousness and satisfaction in our lives, not a larger number of human beings on this planet. One can express but little sympathy with certain exaggerated notions about race suicide. There is no such thing. There is an ebb and flow and a divine law under which some families gradually die out and others come up to the great places of the world. Race suicide, if it existed, would be found in unsanitary conditions of life and in the recklessness by which children are often born into the world.

The best definition of efficiency, if it is to be used as a measure of civilization, has an ethical as well as a material sense. Germany has undoubtedly made an enormous advance in material wealth and in the applications of science. Her ruling classes have also provided for the welfare of the masses, perhaps better than any other nation. It is the concession that they had to make in order to keep a large population contented with their lot. That is their share in the government. But Germany is not efficient in the best sense of the word. Her scholars and her statesmen have betrayed her. One has only to read the paper signed by a number of professors to reach the conclusion that there is too much professor in Germany and too little humanity. The world has been hypnotized up to within a very recent period by Germany's own claim of preëminence and the shock of this war's disclosure is as much a sense of disappointment as it is a revulsion against the professors' claims.

Some Woeful German Weaknesses

Germany is not efficient in her relations with other nations. She is not even efficient in her spy system, for her spies are but children in the hands of Americans. Germany is not even efficient in her science and literature. She is woefully behind the English and the French, except in those applications that bring wealth and power.

In some article President Eliot has well stated what he calls "the precious lesson of the war." "Toward every kind of national efficiency, discipline is good and coöperation is good; but for the highest efficiency, both should be consented to in liberty." We are now going to prove this with the blood of our sons, and unless we succeed against Prussia our constitution will be subject to modification, and we must begin again, like Sisyphus, to roll the rock up the hill in the hope that next time it will not slip away from us to roll back.

A power of initiative in a free government and a power of initiative of its citizens is certain, in the long run, to triumph over a national organization created by a few who have carefully directed the thoughts of the masses. If we put Kaiser Wilhelm alongside of Abraham Lincoln, we see in his royal person only a belated barbarian come back out of a shuddering past to destroy all that humanity has gained in the fight against slavery. We know that the heart of man beats for the freedom of the individual, and that only the drum beats for the divine right of kings. Not one word that Lincoln has uttered is false to the doctrine of Christ. Scarcely one thing of the Kaiser's might not have been said by a heathen king. The whole Christian religion is based on the right of the individual to a life of his own, subject to a true adjustment to the Almighty's laws. Democracy is a final form of government. It may have its failures, and if it fails now it will come again and again until the whole earth is freed from the privilege by birth and the rule of a few.

What Americans Also Lack

All preparation for public service must be based upon a foundation of good citizenship in our whole country, if our officials are to serve well in this republic. A human pyramid can be formed only with strong men at the bottom, and no first-rate public service can ever be built up on a flabby, careless attitude toward civic duties. America is young yet. It is like a boy who has grown far too rapidly, loose-jointed and tall, with unlimited possibilities after his frame shall have been knit into a solid mass. One hundred and twenty-eight years is not enough to bring a nation to its majority, especially one made up of such diverse elements as ours, the dumping ground of all the world for the oppressed and the poor.

Our neighborhood and our international ideals are sound. They are found in the Bible. At the same time we lack cohesion and public conscience in relation to our own Government. Every individual must be regarded as part of the public service, and the first thing he must acquire, whether he be native born or immigrant, is public conscience. In some way the ordinary citizen too often argues that because this is a government by the people and for the people the state owes him something. In that respect, our patriotism is in part a sham, and we have plenty of evidence to prove it. A considerable fraction of the annual appropriation in Congress is the result of a trade among localities, each of which wants something out of the general treasury. The pension bills have been only too often the sop for voters, and capital and labor have already shown us more than once how little they care for the great mass of people whom they class as the public. In the lynching of criminals, and sometimes of innocent people, we find nothing but a total disregard for the good name of the state. These are our failures and we must get rid of them, in order that the beauty of democracy may not be hidden beneath its excrescences. In the matter of public conscience we need a religious revival, and the churches ought to take a share in this. It is their task, as well as ours, to lift this side of our national life.

Elements of American Citizenship

The first demand of our republic is, then, an educated public conscience. No man should expect more from his country than he is willing to give it. Those who whine about injustice in modern society are usually getting about what they deserve.

The second demand on every citizen should be a knowledge of our institutions and the method of government. It goes without saying that the English language is an absolutely essential foundation for this. Most failures in citizenship proceed from ignorance and carelessness, rather than from viciousness. The normal American is right-minded and is morally upright, but slack in his responsibilities to the public. The moonshiner in the Cumberlands makes whiskey because he neither knows his relation to the body politic, nor the evil effects of drink. His whole conception of government makes it something separate and apart from himself, an attitude of mind that, if carried to its logical conclusion, breaks down all government and ends in the ghastly travesty set up by the ignorant peasants and workingmen of Russia under the cor-

rupting influence of the German and of money. The first thing to learn is that freedom does not mean emancipation from all responsibility to others. It means the self-control that permits reasonable surrender to the needs of all men. War has given America the dim vision of a new freedom. In the fall of 1914 no one would have thought it in any way akin to our Civil War, and yet we see it now in its true perspective as the great struggle for freedom, as the struggle for the union of all nations, so that war may never come again. Yet we must have no illusions. Rousseau's doctrine, that man is born free, is false unless the word free is defined in some better sense than that in the dictionary. Men are never free. From the cradle to the grave they have to yield, and every individual lacks freedom in just the proportion in which he has to learn to live with other people. He must think of the wishes and the interests of others. When he has learned how to surrender himself and has learned obedience to the law, then he is truly free. Freedom is no more a natural inheritance than flying or riding a bicycle, but it must be learned if it is to be of any value in a republic. It demands training, hard discipline, self-sacrifice in daily life, especially on the part of those who are chosen to transact the great business of the nation and to lead in the maintenance of our democratic government.

Another much misunderstood word is equality. In its distorted sense, it has encouraged that fatal kind of socialism that would permit no individual to stand out from his fellows in mental or material possessions, and it would eventually kill any form of government; for a nation grows great only on its inequalities, if they be not the type that set up false standards and destroy the soul. The true application of the word is found in opportunity. We are equal, and we ought to be equal as to the opportunity to make ourselves mentally and morally superior. We glory in the greatness and superiority of Abraham Lincoln, and in that equality of opportunity that permitted him to go from a log cabin to the White House. Our most important lesson, then, in connection with American institutions, is the meaning of the two words "free" and "equal." Only when every man, woman and child understands them will democracy be safe.

I venture to state that only a small fraction of the people in the United States know anything about the growth of the Constitution or the reason for adopting the articles fixing a definite relation between executive, legislative, and judicial functions. The Supreme Court has been called the greatest instrument for free government in the world. Why? The most powerful element of citizenship is found in the answer to that question. It involves obedience to law, respect for judicial decisions, and the supremacy of reason over brute force. How many of our citizens grasp the significance of this in the training for public as well as private virtue? It is second only to conscience in the making of good citizens and an atmosphere in which the public can be properly served. The two, conscience and civic education, create the kind of patriotism that would lead a man to refuse a public office for which he had no training. Such a thing as a cabinet officer's resigning because he turned out to be a misfit is unheard of, either because we have not learned what a misfit is, or because our people have not been taught what to give of themselves and what to demand in Washington.

The third element of citizenship is found in true history, not that garble of victories in war, calculated to fill the breast with false pride that cannot see over an imaginary wall surrounding county, state, or nation. Germany is a victim of exaggerated ego, because her historians and writers have totally misrepresented the place of the German in modern life. God has not selected any nation for the dominion of the world. His laws undoubtedly have established ideals that dominate humanity, but never for the purpose of surrendering to some brutal ruling-class domination over men. Bad history, then, may promote bad citizenship. The history of our Revolutionary War usually emphasizes Bunker Hill and Yorktown at the expense of a proper perspective of the tremendous struggle against autocracy and the divine right of kings culminating in the French Revolution. We were fighting against George III and his Germans from 1776 to 1783, and the Declaration of Independence probably had more friends than enemies in England. The outcome of the Revolution was in the interest of democracy for the entire Anglo-Saxon race. It remains to be seen whether this war is the final blow to the old system or not. We might paraphrase Lincoln's words by saying that the world cannot longer exist half democracy and half autocracy. We must smash the autocracy in order that the world at large may recover a conscience and nations may hold a true and wholesome relation to one another. This is why history should be more carefully written and better taught in our schools.

A fourth element toward the foundation for public virtue in office is the education of foreigners in true Americanism. There are millions who must be turned into the kind of citizens found in the old colonies, the men who laid the successful and enduring foundation for free government. Could the American Constitution be written now? Have we the public men capable of striking off such a document? I believe we have, and that many of them have been created out of the children of foreigners. Through our workshops and our schools, and through associations, we should teach ideals of citizenship. This is more important than importing into the United States great examples of art in Europe. The statue of Frederick the Great, set up in front of the War College in Washington, is not a good example of citizenship. His system has ended in teaching good men that brutality is better in the will to force their *kultur* upon other men, than gentleness and love, and his work must all be undone if our conception of human freedom is to be extended over the whole earth. The perpetuation of German or other foreign societies in America is unthinkable, and we ought to break that down in one way or another. Usually the peaceful education of children in our public schools is the best method of proceeding. But we have not done enough by other methods. There should be a great organization within the United States for Americanism, and it ought to be used to counteract all other influence by public speaking and by a more effective propaganda than the Germans can ever again set up in America. This is the melting pot, and it is our duty to make sure that, when the whole mass is fused, it remains an American democracy firm in its convictions and in its demands on public service.

What is Public Service?

What is public service? Almost everything we do that brings us into contact with our fellow man is public, and we are likely to be too narrow in our definition.

Our relation to the government may roughly be divided under four heads:

1 The civil routine or conduct of business in government
2 Civil research and publicity for the benefit of citizens
3 Military training in peace
4 Military training in war.

The Civil Routine or Conduct of Business in Government

This necessarily includes everything relating to the administration, Congress and the judiciary. It is remarkable how little appreciation our people have of government business. No firm or corporation could exist under the present system in every department at Washington. In many cases the appointments, even when based on civil-service examinations, have not sufficient reference to the work to be done. In the higher offices, like the men who constitute the cabinet for the advice of the President of the United States, it is often only by chance that a man well fitted for the position is appointed. The War and Navy Departments may be included under the civilian departments so far as the secretaries and the clerks are concerned, and it is the rarest thing in the world to find, for instance, the secretary of the navy who knows anything about his business. Many million dollars and four years' incumbency are usually required to educate the man in office, and at the end of that time he goes out. Even though a few of the cabinet officers may fit into their positions, fewer still have any knowledge of government or the science of government.

When we come to the legislative branch the matter is even worse, because men are elected to represent constituencies on issues that have often no relation whatever to the transaction of the government's business. Congressmen when elected have their principal interests at home and very generally do not feel under any obligations whatever to make a study of government. Their votes are cast too often without knowing anything about the subject on which they are voting. It may be said that this is also true of legislative assemblies the world over, but it ought to be better under a democracy that throws responsibility on the individual, the responsibility for fitness and for citizenship. The lack of conscience in connection with our legislation is often disclosed in the Congressional joker. A bill that has passed the House of Representatives and the Senate may go to conference on some differences, and there have inserted by some congressman either without intelligence or without conscience certain things that were never in the original bills and never had been discussed. In our appropriation bill there is wholly a lack of system. Attention has been called to this time and time again by men who have held high office and are well acquainted with our methods. Millions of dollars are squandered because there is no budget and no plan, just as millions of lives may be lost through the failure of concerted action by the Allies in this war.

Another feature of this shows a lack of understanding on the part of our people or a lack of enterprise on the part of the engineering profession. A very large part of the business of this country relates to industries, transportation and engineering enterprises, and yet there is hardly a man in all Congress who has any grasp of the engineering matters. The curious part of all this is that our Congress does not know that it doesn't know. What would be self-evident to a scientific man must be beaten into a congressman by means of a trip-hammer, and yet our people put up with it.

We have every reason to feel confidence and pride in our judiciary, so far as the Supreme Court judges of the United States and of the states are concerned, but the courts have already been too much criticized by their own judges and lawyers to render it necessary for me to make any explanations whatever on the lack of training for doing business. Many cases have been known to hang on for years. Trials that should have been dismissed in two days have been exploited before the public for weeks. The Thaw case that was tried in New York was a disgrace to any community. The newspapers without public conscience at all published broadcast the most nauseating details calculated to satisfy only a morbid curiosity or to degrade the moral and literary taste of our youth. The difficulty with this is that the courts permit it to continue on the grounds that the newspapers publish what the public wants, the same grounds that would permit the sale of poison because the public wants poison.

Research and Publicity for the Benefit of Citizens

In our scientific departments of the government, we have in a way emancipated ourselves from the accusation of inefficiency, although much useless stuff is published. The Bureau of Standards, the Agricultural Department, the Geological Survey, the Bureau of Mines, are unquestionably helping to educate our professions, our workmen and our farmers into higher efficiency. The men appointed to office under these different departments are usually well-trained men. They can naturally be classified by some kind of civil-service examination as the men in the business departments cannot.

Every state and every community unquestionably feels the effect of what we may call publicity at this time. The food-conservation program carried out by a mining engineer is really creating a revolution because the American people have been exceedingly wasteful and they are learning now something of the moral effect of saving. Mr. Hoover is only an instance of what can be accomplished by putting a trained man at the head of a department. Mr. Scott at the head of the War Industries Board and Mr. Coffin at the head of the great industrial survey, were other examples of what our profession may contribute to the success of the government. Too often, however, the profession of engineering does not realize its usefulness. We belong to all departments, those of business as well as those of scientific research, but it is the latter that claims us and we should be ready at all times, for this our highest function in the service of the people. Few engineers confess themselves able to speak on engineering and governmental subjects. We hold a duty to this republic, and we ought to fulfill it by learning.

Military Training in Peace

One of the most astonishing phenomena in modern times is the ease with which the conscription bill passed Congress and the extreme ease by which it was enforced. Practically no objection has been raised except by a few malcontents and crazy people, and, yet, a few years ago no one was ready to listen to the words *military training*. Perhaps the speakers on the subject emphasized the words too much and gave the impression that they meant a large standing army, which we shall never want. If there is to be service in war, the whole nation, every individual, man, woman and child, must share in the sacrifice, and must be prepared. The hiring of volunteers is no longer moral. Only time will indicate how much we owe to Leonard Wood for his untiring effort to wake up the country to the importance of military preparation. The whole matter of training officers has been formed directly around his Plattsburg camp, and it is not too much to say that the training of all our men for service abroad is based on his theories. We listened too closely to the politician a few years ago and we have been fed up with three or four thoughts that would destroy the discipline and the correct reasoning of any nation if that nation believed them. The springing to arms of a million men in a single night is that peculiar kind of idiocy that is accepted in the remote agricultural regions where

ignorance of history is the dominant note. We engineers are not too proud to fight. We do not want peace without victory. We were not kept out of war and we do not want to be kept out until little Belgium has all that belongs to her again, all except the dead and the virtue that has been outraged by a brutal soldiery. I have never been a believer in the German system, because it gave too much control into the hands of a comparatively small number of officers constituting the German general staff. The idea of service beneath that system is, however, good. It makes for the education of young men and for obedience to law. Our country is not built up on the idea of obedience to individuals. It should, however, learn that liberty is based on law, and can never be anything else. It is hardly necessary at this time to dwell long on military training in time of peace. We have had our lesson and we shall probably never go back to the old system of a small standing army and a smaller militia of more or less efficiency, usually less. The conception of public service has been drilled into the people by stern necessity to maintain the liberties of the world, so that we shall probably have some kind of military training long after this war is over. Everyone has noticed what a difference the camps make in the slouchy individual who enters, to come out the trim, erect soldier.

The old pioneer days when every man was trained to use a musket have long ago passed, except in a few places not yet settled. We cannot possibly depend on the initiative of communities to teach our boys how to shoot and in fifty years from now a gun of any kind will be as little understood as the archaic engine put into operation by James Watt. Consequently, we must necessarily have some artificial methods of teaching the youths how to shoot and how to act in coöperation with other young men.

Military training is probably the best method we have of Americanizing the young men who come to us from foreign countries, and every one of them ought to be required to take his turn of service. It is not necessary that a foreign citizen making his home here, should be required to bear arms against his old country, but he should, for the sake of teaching him American ideals and American institutions, be obliged to take his place in the camps with young Americans, if he is permitted to make his living on our soil. The simplest of military training is learning how to keep step and that is a great moral influence. We need it beyond everything else in this country, where the forces are so pronouncedly centrifugal. Keep step! That does not mean that the men have to think alike. It does mean that they must act together for the good of our country, by a willing obedience to the control of men selected to manage the affairs of government. Keep step! The great leveler between the rich and the poor who must work together, whatever their homes may have been. It is the great simplifier of human relations. Keep step! The collective action that will put our public servants into a higher standard of training and education for their job. Keep step! There is nothing more inspiring, more beautiful than the march by of an American regiment. There is no goose step about it. It is the free swing of a free people that will never be trammeled by military dictation.

Military Training in War

This nation already has that definitely planned out and our conscription bill has called many thousands to the colors. The selective feature of the bill has been more or less lost sight of, and its spirit has been violated up to the present time. Selection on June 5 amounted simply to a lottery method of choosing men for the service and little attention was paid to selecting them for special positions, in such a way that an army might be formed most quickly. Our young men are graduating from the schools, colleges and technical institutions. Many of them have a training similar to that found at West Point and Annapolis, but comparatively little use has been made of this fact. There are new training schools established that will eventually turn out men for specialized service, but here are, and were, many young men all ready for special service flung into the ranks. We have had warning of this in the mistakes of England at the outset of the war, and we have done nothing about it until now. One of the very curious anomalies in connection with even temporary exemption, is found in the recognition of the special importance of dentistry and the study for the ministry, while the industries have been recognized only so far as their workmen are concerned. If the present system is maintained, our engineering colleges are going to disappear in a comparatively short time, and the government will have to set up special schools which will take years to fit men for the places that the engineering schools can fill. Training in war is very quickly seen to be the heir of mistakes in training during peace. Inasmuch as we had no training before this war came on, we are heir to nothing and all of it will have to be learned.

The most serious part of this whole business is that training in time of peace is of no use whatever unless something is done about a supply of munitions and weapons to be used in time of war. In that respect we were worse off than any of the belligerents except little Serbia or perhaps little Portugal, whose standard we just about reached at the outbreak of the war. That is what rising over night with a million men always means in the mouth of those ignorant of history, even though they be in high places.

Need Greater War Publicity

The training for the present war has a very important corollary that we seem for the time being to have lost sight of. A press bureau is established in Washington for the dissemination of information and its duties have been too narrowly defined. We need now extensive propaganda on what we are actually fighting for. The President well stated the case in his reply to the Pope's proposals for peace, but the people know only the call for troops and for money. A few pacifists and their friends, the German traitors, are concealing the great moral issue behind this business. We must have concerted and widespread publicity of a more penetrating kind. What do the Central powers stand for, the Prussians, the Germans, the Hungarians, the Bulgarians and the Turks? They are all banded together under the compulsion of the Prussians, whose ideas of war as a good thing and brutality as the justifiable method of striking terror into the rest of the world are wholly abhorrent to us. Their success means our failure and we must bring this home to every American, instead of taking things placidly while the German newspapers are fooling the public. We must, as engineers, carry back home the determination to awaken the country whether we are organized for that purpose or not. Every bit of camouflage should be torn off so that we Americans can see the vision of death beneath it. The old Persian proverb, "He that knows not and knows not that he knows not, he is a child, teach him," tells us the daily work of all our spare moments.

As part of the general publicity we must dwell on saving for the war. Economy in food, fuel and clothing is the moral duty of everyone. One of the saddest sights in an American

community is the organization of merchants to tell people to go on in their former mode of life and to buy. Carry this idea to its logical end and we shall lose the war. Prosperity has not come. All boosting of prices is blood money, and the men who are taking advantage of the country's need will be tainted all their lives. One of the most necessary distinctions in business is the priority of essential industries. All unessentials must go and all excess profits must be saved for the success of the country in war.

Engineers Must Kill Conspiracy

The twentieth century is still young, and we do not yet know what it will represent to the future historian. Will it be the debauch of science or will it mean a new birth to Christianity? It is our task to decide this. There are two tendencies; one toward greater comfort and luxury, and one towards greater service. The first can plunge us only deeper and deeper into war for the control of a commercial output. It can only bring us more firmly under a governing class derived either by birth or by commercial success. The second means the complete emancipation of the individual trained to think of service as the chief source of good government and happiness in life. The only theory that will hold men together is that of service. All others, like the control, for instance, under an overlord, are but the cracked shells of old doctrine. This war is their last stand against a modern world, and our work as engineers and citizens is to help prepare for the new day when the rule of kings shall have been swept away. Our profession has been morally responsible for America under the century of invention just passed, as it is we who have created the applications of energy and it is we who have given the wealth of the world into the possession of a few men. This war will create many millionaires. It will place vast power in the hands of the strongest and most ruthless. It will strengthen the trade unions into autocratic groups defining what each individual shall be permitted to do, and what wages each shall receive. Are we to stand by and accept this? Are we to remain forever blind to our own power? There is only one answer to that. We must, as engineers, go forward with our own countrymen to kill this conspiracy against freedom and, then, we must give our lives to fight, that science may never again be employed as a destructive agent in the hands of a few unscrupulous men.

What Can Our Society Do?

What does our Society stand for in the scheme of this world's affairs? We know that there must be more or less selfishness and there will be often a great difference in the general fundamental principle underlying organization. Coöperation may have as its motive one of two ideas; first, the desire to benefit others, and second, the desire to benefit the organization. Sometimes it is difficult to classify under either of these, as the benefit to an association is often benefit to the public, in lifting the general average. And yet when things are traced back to their origins, it is possible to place most associations in their true category. For instance, the missionary societies—and we may with equal propriety say the churches—are altruistic in their origin, and, in the main, they remain so. Charitable organizations, hospitals and colleges are unselfish, and grow out of a sincere desire to give one's self to the service of others. Our own Society belongs to that class which benefits others as it benefits itself, for it is essentially educational in its purpose. As the years have passed, we have come nearer and nearer to a true conception of what our public relations should be, and this war has brought about a sudden large vision of our duties. They are not to be found in reforms put forward by the weak, or by self-seeking manipulators of public opinion, either within or without our Society, but rather through a state of mind. We owe it to our country to think clearly and rightly, and to throw the whole weight of our Society into the scale for sound legislation, good government, and public conscience. The engineer's philosophy is shown in his actions rather than in his words, because he has never learned to explain himself. It is expressed in the desire to serve. No profession can claim a higher motive than the silent men who fill our ranks.

We believe our Constitution to be the best instrument of government ever produced, and that under it all mistakes and imperfections tend to correct themselves. Our advantage is that conspiracy can never thrive, and there can never be a policy fatal to other nations. We can discuss any question of national policy and we can always have publicity against any hurtful tendency. The newspapers have always exhibited a high degree of patriotism when the need comes for discretion, and we may depend on them in times like this to stand behind every program for the good of our country. However sensational the headlines may be, we know that behind them is always a sincere desire for the greatest good to every citizen. Whatever our faults may be, they are always in the open and, like bacilli exposed to the sunlight, they die. That is, after all, the reason why a republic or some form of democracy is always superior to an empire under a few men.

Our country is the home that we love and, as engineers, we must feel a deep responsibility for its welfare. It is given into our hands by our forefathers and we know its virtue, and, God willing, we shall strive to make it the perfect example of what life on this planet shall become when wars are past.

THE ENGINEERING SOCIETIES IN THE NATIONAL DEFENSE

By Gano Dunn, New York, N. Y.

Engineers are, indeed, coming into glory and honor—glory in the things we were reading about in yesterday's and today's papers, as to the behavior of the very men which our national engineering societies recruited in New York through the agency of the Military Engineering Committee only a few months ago, and honor in the ways that were referred to by your president in his address in which he mentioned the fact that the engineering profession and the corporate societies representing them are having an ever-growing opportunity to do their bit for the Government at this critical time. The spirit, the intelligence, the usefulness of the engineer is a matter of common comment. I have talked with several university presidents who remarked upon the high percentage of enlistments and volunteering for service, particularly of the men in the engineering schools, and Dr. Hollis has not exaggerated the part that engineers are playing, and are yet to play, in respect to the things in this great war which we have only just begun to appreciate and understand.

I should desire this morning to bring to your attention some of the things that are now being done by engineers and engineering societies. Adequately to treat of what the engineers are doing would take days, if not longer, and I can only refer to it. One has only to be in the atmosphere of Washington a short time to see that the whole Government of the United

States in respe[illegible] and [illegible]al preparation rests upon a foundation of [illegible]ness.

My task is encyclopedi[illegible], and I beg your indulgence if I but hastily skim over it. I wrote to the representatives of thirty-two different engineering bodies that are now in contact with the Government, asking them to give me authoritatively, although briefly, a résumé of what they were doing in connection with the national defense and with the war. It is beyond our time for me even to go through the replies, but I hope to put them in the record, and they are certainly a scroll of real honor to our credit.

To begin with, there is the Naval Consulting Board. The Naval Consulting Board was intended to bring formally to the service of the Government the scientific and technical ability of a group of the best advisers on engineering lines in the country, and the Government had the conception that if it asked the engineering societies to select these advisers the selection would be better made than if it itself attempted to make the selection. Consequently, two representatives from each of the different engineering bodies were nominated, and under that nomination appointed by the Secretary of the Navy, and that board has been doing able service since the time it was appointed, starting with the Committee on Industrial Preparedness, which took an inventory of all of the industrial resources of the United States. Later it proceeded to report to the Government on the needs of the experimental development of improved devices, and finally it established connections whereby its services might be made available and useful to the Army as well as to the Navy.

It now holds an honored position in Washington, where it acts as a Board on Inventions, and substantially all newly invented devices that are brought to the attention of the Council of National Defense, through various channels, are now referred to the Naval Consulting Board to be passed by, or turned down if they are not useful, or given attention if they are valuable. The Naval Consulting Board has offices at 15 Park Row, in New York City, and has a large force of clerks. The devoted services of its members are constantly given to going through thousands upon thousands of suggested devices from engineers, citizens, and others all over the country.

The Naval Consulting Board was created long before the war. The next body in order was the National Research Council. The National Research Council was started because it was seen that, just as in the Civil War, such help as was given by the National Academy of Sciences, created by President Lincoln, and is now being given by the national engineering societies, would be again needed. The Government acted, therefore, under the Charter of Congress granted in 1864 to the National Academy of Sciences, among the provisions of which were the requirements that the members of the Academy who then represented what we now represent, the engineering as well as the scientific intelligence of the country, serve the Government on request, in whatever direction called upon, without compensation. And they did an unusual amount of service at the time of the Civil War.

Between that time and now, entirely aside from their scientific functions, they have reported on about sixty different questions to the Government. It was seen that this body could be made of great use at this time.. and consequently President Wilson requested that it enlarge its scope and bring itself, as it were, down to date, and include the increasing branches of science that were not known in the old days, including engineering, and to do everything to put at the service of the Government the scientific talent of the nation.

In accordance with this request the National Academy of Sciences organized the National Research Council which may be described as being partly a federation and partly a creation, through which there comes to one single focus every important scientific agency in the United States. It reaches the universities, it reaches the industrial laboratories, it reaches the engineering societies, it reaches the isolated workers in pure science, but the keynote of the National Research Council is science rather than engineering, and engineering plays a part in it only as it deals with pure science aand applied science, in short, what we call engineering research.

When the war broke out it was only natural that the Council of National Defense should request a connection to be made between that body, which had existed for nearly a year, and itself, and since the war the National Research Council has almost dropped all other activities and directed its whole efforts to the problems in science that have been handed down to it by the Council of National Defense.

The next body in order of creation was the General Engineering Committee of the Council of National Defense. When the war broke out, our Society, in common with other engineering societies, immediately, and with a patriotic devotion, offered the services of engineers to the United States, directly to the President; and I do not think any of us realized at that time just what we were offering—quite a little confusion has arisen since as to what it was, but I do know that when we made the offer we did not intend to limit it merely to our engineering service, but we meant to go to any lengths that might be necessary.

Later on it came to be obvious that through this offer to the President we had not intended to convey the offer of our military services, and among other things we all remembered then that we were members of an even greater society than The American Society of Mechanical Engineers, we were members of the Society of American Citizenship, and that through membership in that greater society there came to us calls for military services and other things, and consequently the offer to the President of the services which we made through our Society was regarded as conveying only the offer of engineering service.

The President turned our offer over to the Council of National Defense, and from Dr. Hollis Godfrey of the Advisory Commission of the Council, an invitation was received to appoint representatives to form an Engineering Societies' Section of the Engineering Committee of the Commission. The Society acted officially upon that invitation and sent representatives to a conference in Washington, who met together with representatives from other societies.

From my point of view, this General Engineering Committee as it stands now is the official connection of our societies with the National Government; but the spirit among the engineers who want to serve the Government in more ways than this Committee renders possible, has caused the springing up on all hands of numerous other committees. I am going to read to you a list of the committees of engineering bodies which were in existence at a time, a short while ago, when outwardly and from the point of view of the Government there seemed to be so many committees that they were crowding each other, overlapping, and in their actual relations to the Government carried with them a certain degree of possible confusion, which was brought to our attention and which some of the members of our societies have been endeavoring to remedy.

These committees or engineering bodies are: Naval Consulting Board, American Engineering Standards Committee, Engineering Committee of the National Research Council, Com-

mittee on Gas and Electric Service, Emergency Construction Committee of the War Industries Board, the Intercollegiate Intelligence Bureau, the War Committee of the Technical Societies, the Engineering Council, the American Engineering Service Committee, the Aircraft Production Board, the Aircrafts Standardization Committee, the Aeronautics Committee of the National Research Council, the United Engineering Society, the Engineering Foundation, the American Society of Civil Engineers, The American Society of Mechanical Engineers, the American Institute of Mining Engineers, the American Institute of Electrical Engineers, the American Society for Testing Materials, the American Society of Automotive Engineers, the American Electrochemical Society, the Illuminating Engineering Society, the American Chemical Society, the American Gas Institute, the American Society of Refrigerating Engineers, the American Water Works Association, the National Electric Light Association, and the Association of Edison Illuminating Companies.

The mere enumeration of these engineering bodies itself is a bright light on what the engineers, as societies, have been doing for the Government. It does not begin to be a token of what engineers as individuals are doing for the Government.

As societies, however, there has been some confusion among the various societies, due to overlapping, and there has been also some lack of distinction between engineering services on the part of individuals and corporate services on the part of societies. For instance, one of the great services which no single individual could render the Government, but which a union of societies could wonderfully render the Government, is the question of engineering personnel. So great has been the demand in Washington for competent engineers for this, that and the other service that they have not known where to go to find the men. They first went to their personal friends, to the members of the engineering profession already in the departments, and to those whom they were acquainted with, but soon the supply of acquaintances of these men and the men with whom they were in contact was exhausted, and the authorities were simply at the end of their capacity.

It has been very obvious that at least one of the functions that the national engineering societies could perform was to serve as a center to which the Government could go and find an adequate roster properly classified of all of the men who could render service to the Government, so that the services of these men promptly could be called upon. Through a misconception, the responsibility for which I will not attempt to go into, the General Engineering Committee, which, as I have said, in my view is the official connection of the societies with the Government, declined to furnish the required roster of the personnel. I ought to say that it declined to do it on the recommendation of its chairman, Dr. Hollis Godfrey, who at the time was under some instruction from another branch of the Council of National Defense, which had in view the classifying of engineering service or labor generally, and consequently had in view the grouping and listing of this service in another department of the Council of National Defense, where it was hoped there would be a much broader and more general listing of labor than that which we now usually consider as labor, but be it as it was, the General Engineering Committee declined what, in my opinion, is the principal opportunity to be of service to the Government.

There then sprang up the Intercollegiate Intelligence Bureau for the purpose of making good this deficiency to a certain extent. Its origin was not in the engineering societies, but through an engineer, one of the prominent members of the American Institute of Electrical Engineers, Dr. William McClellan; he organized 170 colleges into a sort of league to supply to the Government men of technical training and engineering qualifications. He went at it through the colleges, because he is president of the Wharton School, and also because he felt that through them he could get in contact with a greater number of engineers and could accomplish better work than in the other direction.

The Engineering Council, which is a body destined to represent not only the great national engineering societies which are members of the United Engineering Society, but all of the great national engineering societies, also took up the question of personnel. It conceived its function to be a very broad one and organized in an endeavor to make certain contacts with the Government, leading up to that through the Naval Consulting Board, through the National Research Council, and through the General Engineering Committee, and there was also created under the Engineering Council the War Committee of the Technical Societies, and also a committee known as the American Engineering Service Committee; Dr. Brunton is chairman of the former and Mr. Foran is chairman of the latter.

These committees went to work vigorously, headed by Dr. Hollis in the Engineering Council, and from the beginning have seen the importance of a registry of engineers and they actually started to accomplish a registry of that kind. When representations as to what these committees had done and were doing were made to the Government, and now speaking from my own point of view, and with the hope not of producing controversy, but of allaying it, the committees were not fully aware of what had been done already by the Naval Consulting Board, by the National Research Council and by the General Engineering Committee, all of which bodies had been in efficient contact with the Government, contact through channels that had been grooved more or less bright by use, and therefore the newer committees wrote to numerous agencies of the Government and interviewed them, and from the Government point of view canvassed the Government as to what channels they should use in their relations with these various activities.

The confusion that arose, although not serious, required straightening out. For instance, the National Engineering Society, as such, had nothing to do with the appointment of the National Committee on Gas and Electric Service. They were more or less unfamiliar with that committee and its work, yet of all the committees in Washington that committee has probably done as much as, if not more than, any other committee in specific and concrete service rendered to the Government. That committee is a committee representing public utilities, or rather it represents the Council of National Defense—it is a committee of the Council of National Defense itself—but it instructs them and knows about the public utilities, and so today is charged with questions of coal supply and of power supply, questions of keeping the industries going that are engaged in munitions manufacture, questions of cantonment inspection and cantonment supplies.

The gist of the matter was that a certain member of our Society, Mr. Swasey, the Father Abraham of the Engineering profession, was down in Washington and learned of some of these things. He endeavored to bring about coöperation and understanding among the thirty-two different engineering agencies. He called a meeting of the representatives of these organizations, and they all most promptly responded and met in Washington. That meeting was an eventful one in the history of the relation of the engineering societies of the

country to the Government, for the knowledge was there brought out of the vast amount of service that was being rendered to the Government by engineers, and everyone present at that meeting was astounded at hearing how much everyone else had been doing, and the mere getting together of these committees is a thing that is going to solve the temporary and minor difficulty of a unified relation of the engineering societies to the Government.

For instance, at that conference we heard the representative of the Society of Automotive Engineers say what his committee had been doing. That Society has been intensely vigorous it has been of actual, concrete and real service to the Government in a way that cannot be known: in fact, one reason why the members of the societies have felt impatient at their Washington relations is because the work, as such, cannot be dwelt upon in detail among them. The Government requires that almost all the work of these various committees and societies be confidential and shall be kept to themselves, and that is one reason why the membership of the Societies have felt that they were not doing their bit, when in fact they were doing all that the Government so far had called upon them to do.

The status of the matter at present is that that joint meeting in Washington appointed a sub-committee to confer with the Engineering Council and with the governing bodies of the national societies, with a view of reporting back some general plan whereby the chairman of the War Board, for instance, would not be receiving four different letters from engineering bodies, each inviting him to take up problems of a certain kind through that particular committee. It is confusing to that chairman to receive such letters, and moreover it shakes his confidence in the ability of the engineers to organize their work effectively and to do the things that they most want to do.

I am afraid I have omitted ninety per cent of the things I wanted to say in regard to the activities of certain of these committees, and I perhaps ought to speak about the War Committee of the Technical Societies. That committee was intended originally to be a vehicle of information between various Governmental activities and the membership of the national societies. It was intended to be of service both ways. It was intended to satisfy this demand on the part of the membership by knowing as far as possible what was going on. It has recently established a connection with the Naval Consulting Board, and the general view of the engineers now interested in the Washington relations is that there never can be too much service in Washington, and that there is room for every committee. Colonel Carty, who presided over the conference called by Mr. Swasey, said that the whole thing is too big to be controlled by any one committee, and it is realized that the more there are of these committees that represent real service, the better it will be, and all that is needed is a little better directive force and a little more inquiry and coöperation before taking up with the Government questions that may have already been settled, in fact, by other agencies.

The situation as it stands now is one in which we may all take great pride. The General Engineering Committee of the Council of National Defense is in the awkward position of being asked by its chairman to resign. This is through, as I understand it, a fancied conclusion that service on that committee is incompatible with the ruling of the Attorney-General to the effect that men may not serve on committees of the Council of National Defense when they have other business relations with the Government. The business relations of the men in the engineering profession serving the Government are so numerous that if that principle were really carried out in fact, the Government would be deprived of the service of engineers; or, on the other hand, the industries, the engineering projects, and the very great works that are now being accomplished for the Government would be robbed of the directing heads that are producing them. Neither of these alternatives is for a moment conceivably possible.

This opinion of the Attorney-General has been interpreted by the Secretary of War to mean that no man may sit on a board in Washington when that board is engaged in deliberating upon the award of a contract to a company in which that man is interested. That is only common sense. It has gone one step further, and says that no man may sit on a board when that board is making recommendations to another board, which other board may be empowered to award contracts, except, in this case, the man is not forbidden to sit on that board, but if he sits he must file with the second board a statement of his complete relation to the contract that is under consideration, and state what other interests he may have with it.

I think one reason for the general resignations that have occurred in the Council of National Defense has gone a good deal further than this technical situation. The Committee has been overgrown, overgrowth indicating rather a lack of authority, which the springing up of so many committees always indicates. The authorities wanted to reorganize the whole matter, and certainly that reorganization is now in force, but whether it will take the form of continuing to ask for the resignations of the members of the General Engineering Committee of the Council of National Defense, or whether that committee can be regarded as an exception, because it is a non-commercial committee, and whether that committee can be permitted to retain its relation there with the Advisory Commission, or establish new relations directly with the Council of National Defense, the same relation that has been established by the National Research Council, is not yet to be known. However, whatever it is, the principal thing which is now to be settled is not the relations of the twenty-eight of the thirty-two committees, whose names I have read; their relations are very satisfactory; they are doing splendid work for the Government: they are a credit to the societies that have created them and the men who are in them. They are one of the good right arms of the authorities in Washington. Any confusion that may have existed lies in respect to the relations of the engineering societies, as such, to the Government; in other words, our own corporate relations to the Government for those things which we as societies may do, which we as engineers do not do, and under the leadership of Mr. Swasey that general question is now being happily and kindly worked out and thought out in a way which will result in the Government continuing to get not only the service it has been getting, but such increased service as the near future will lead it to demand.

We are not yet really in the war. Times are coming—they are predicting it in Washington—when the service we have so far rendered will be like but a little cloud on the horizon. Our duties will increase: our opportunities will increase. I do not think the patriotism of the engineering societies can increase. It has been at par from the beginning.

But, gentlemen, those of us who felt that because they were not yet called upon they were not going to have a place in this great war; those of us who have felt that because of some defect in the machinery at the top they were not being put in touch with the things they could do; those of us who have felt that way, I think, will soon, and very soon, have a

call for everything that they can render. In Washington, the views of the authorities are all in one accord as to the patriotism, the usefulness, the distinguished service and the ability of the engineering societies and their representatives in the national service. We have been a credit to ourselves in a big and fundamental way, even if some of our superficial relations have not been quite as orderly as we might have liked to have them. I have been told there is not yet on record a single case where the Government has actually asked an engineer to do a service for it where he has not responded, and that is a badge of honor which for our profession I hold very high.

SPECIAL EDUCATION IN TIME OF WAR

By DR. CHARLES S. HOWE,[1] CLEVELAND, OHIO

I AM asked to talk to you about some of the problems facing the engineering colleges. These problems are definitely connected with two questions, which I do not propose to discuss at any length. The first is: Does the country need engineers in time of war? And the second is: Have we enough engineers now to supply the need during the war and after the war is over?

It would be needless to mention these questions were it not for the fact that if the present methods are carried out there will be no teaching in engineering colleges after a few months have passed, and the engineering colleges are the only places where systematic education in engineering is given. Engineering instruction is carried on to some extent in some shops, and very efficiently carried on, but there is no systematic attempt made over the entire country to give engineering education in the shop. Hence the colleges of engineering are the institutions to which we must look for engineers in the future if we need them.

It is surely not necessary for me to answer the first question after you have listened to the address of President Hollis and the address of Mr. Dunn, and it will be especially unnecessary after you have listened to the other speakers of today. I shall not attempt to discuss that question.

As to the number of engineers needed, it seems to me that all of you will agree with me that we do need to continue the supply of engineers, because we shall need more while the war is going on than we have now, and we shall certainly need them after the war is over. You have found in your business the drain upon the supply of engineers now. You know in a good many cases it has been difficult to get men for engineering work in the firms with which you are connected. We in the colleges know we cannot supply any of the engineers that are demanded now and asked for every day, that it is utterly impossible to send a man to any place unless we take some one who already has some position, and that the demand now is larger than it ever has been before, and we believe it is going to continue.

Therefore, it seems necessary to train engineers for the future. But the drain upon the engineering colleges has been very great. As soon as war was declared, it seemed as if every college student—I can speak only of the engineering colleges—wished to go into the army. We had very great difficulty in keeping any of them in the colleges. While they were determined to go, the members of the faculties were trying to keep them out of the army as far as possible, because it seemed to us that these boys who were being instructed to become engineers would be of more service to the country after they had been trained as engineers than they could possibly be as privates in the army. If the situation were more critical, if the enemy were at our door and every man had to shoulder a gun, the case would be different; but as things are now, and as the supply of engineers is limited, it seemed to us that we ought to keep these fellows in the colleges until after they had been graduated. But it was impossible to do so. They enlisted in every form of service—they went into the army, the navy, the flying corps, and the ambulance corps. They are carrying ammunition in automobiles all over the battlefields of Europe, and they are in every kind of service that the army has to do. They are going now in large numbers, and most of the engineering colleges have lost anywhere from twenty to thirty per cent of their men in the last year.

These figures merely include the number who would be trained as engineers and graduated within the next few years, but now, by a ruling of the War Department, young men have the privilege of enlisting up to December 15. After that date, if they are drafted, they must go into the service for which they are drafted. The result is that there is the greatest uneasiness among all college students. They are leaving our colleges in large numbers, and unless something is done to allay this uneasiness before December 15, we shall lose a large number of men who ought to go into the army as engineers.

According to the classification that has just been given out, college students will be in Class No. 1, and that class is to be exhausted before any other class is drawn upon. Consequently the engineering students will all be taken out of our colleges in the next draft unless something is done to save them for their professions. I would not at all say that the boys object to this—these fellows are young, they are full of red blood, they are interested in their country, they are anxious to have a hand in the struggle that is going on at the present time. They want to get into the struggle, and it is with great difficulty that we keep them out of it. But we who are charged with their training are trying to look at this thing in a cold-blooded way. We say, Are these men going to be needed for a special service? If they are, they ought to bear in mind that every man should look forward to the best service that he can render, and not merely try to get into some kind of service.

Plans for Drafted Students

The colleges, recognizing the difficulty before them, have tried to interest the War Department in the question of saving some of these students, because after the second draft is made there will be only those under twenty-one years of age—and not even those, if the draft age limits are changed, as seems probable—and those physically unfit.

You are all probably aware that the medical profession took up this question last fall, and that an act was finally passed which permitted medical students to enlist in the Medical Reserve Corps, and the men who so enlisted are not liable to draft, are not liable to be sent into actual service until after they have secured their degrees, and so the Society of American Universities has requested the Government to allow engineering and other scientific students to enlist in some reserve corps until after graduation. They have asked that chemists and engineers and physicists and bacteriologists and others pursuing scientific work might be allowed to go into one or another of the numerous reserve corps where they would, of course, be subject to Government control, but would not be called upon until after graduation. The authorities at

[1] President, Case School of Applied Science.

Washington turned down this request. A similar request made by the Association of State Colleges, has not been acted upon as yet, but probably will be turned down, because it is similar in character to the request made by the Association of American Universities.

A request has been made by a number of colleges that students who are enlisted shall be furloughed back to their institutions. That has not been acted upon. It has been suggested to the authorities, I believe by army men themselves, that a certain proportion of engineering college students be exempted from the draft until after graduation. Some of us object very much to that word "exempted." We do not want our college students exempted from service. We want them in the army, if they ought to be there, by the draft, but we would like to keep them in colleges long enough so that they may finish their training.

Another plan which has been proposed is that engineering-college students who are drafted be detailed back as drafted men to the institutions from which they came, provided that when they were drafted they were in a state of proficiency in their work in the college so that it is reasonably certain that they can be graduated with credit to themselves and the institutions with which they are connected. A part of this same plan would be to have these men wear their uniforms and have it understood by all of the students that they were soldiers in the army, and that the colleges be required to give them military drill, so that they would not be losing altogether the training which they would have had if they had continued with the active army.

Another provision is that the colleges shall report the standing of these men to the War Department at the end of each semester, and any man who is not doing efficient work shall be immediately sent to his regiment. Another provision was that after graduation these students should immediately go to their regiments as privates and work up to positions as non-commissioned officers and perhaps commissioned officers, if they were competent for that kind of service and were needed for it.

It seemed as though one or the other of these methods would permit us to keep our students in college long enough to train them for the various branches of service and that then they could be sent wherever they were needed. The Government has seemed indifferent to the necessity of maintaining the supply of trained engineers. I think that is because they have been so busy with organizing the army that they have not been able to give any time to the question of training the engineers. I was in Washington last Saturday with a committee of another society and took up this question with the War Department. It seems from what we learned there that the War Department is greatly interested in this question and is now taking steps to provide adequate training for a certain number of engineering students. The details of the plan we do not know—and cannot know until the matter has passed through the hands of the Secretary of War, but it looks now as if some method would be adopted at Washington before very long whereby engineering students may go on with their training, just as medical students are now going on with their training.

[In connection with this it might be interesting to note that the A.S.M.E., through the Engineering Council and the Society for the Promotion of Engineering Education, has passed resolutions to the Government that the preservation of a source of supply of engineers be given careful attention. These resolutions have already been acted upon and provisions for drafted engineering students made.—EDITOR.]

Special Training During War Time

Another question which has been before us is that of special training during the war. I think that all of the colleges have insisted on military drill as part of their work. Many of them have made this training compulsory, although it has been exceedingly difficult to secure army officers to take charge of that drill. Nearly all of the colleges which could not secure army officers have appropriated money from their own treasuries to pay for the services of men who have had experience as officers and who are not eligible for active service in the army at this time. Nearly all of the colleges have established some military-engineering work. For instance, they have taught the students how to build military bridges; they have taught them how to lay out intrenchments; how to make rapid plans of any region of country, how to do reconnaissance work; how to make maps which could be used by the army officers of any section of the country, and various other things connected with military engineering which are very desirable for any officer and perhaps for any soldier to know.

Work has also been given to some extent in the mechanical- and electrical-engineering departments; that is to say, men have been trained in the application of electricity as necessary in the army. Some of us have gone to the military-engineering schools, where we have been able to find out just what instruction is given the army men in signaling, for instance, and in the use of searchlights, as well as in military telephony and telegraphy, and courses of study have been introduced in many of our engineering colleges to better prepare men for that class of work. The Chief of Ordnance suggested one day in Washington that the colleges give their students in machine design in the future the designing of heavy guns and gun carriages instead of the ordinary machine design, and offered to furnish blueprints which would form the basis of some of this work.

Some of our institutions will teach their chemists a great deal about explosives, giving them not only the chemistry of explosives but the methods of manufacturing the explosives. I do not mean that they maintain explosives factories on the college grounds—that would not be allowed—but they teach them the methods of manufacture, so far as they can, without actually manufacturing the explosives, and teach them the chemistry of all of the ingredients that go into the explosives.

Quite a number of professors of chemistry have visited the explosive factories in order to find out the latest methods in use in the manufacture and handling of explosives, as well as to ascertain the different materials that enter into them. So that in all these ways the engineering colleges are trying to give their students some information which will be especially useful to them in the army if they are drafted, or if they become officers in the army.

There is still another important question before the engineering colleges: If they lose all of their men over twenty-one years of age, except the physically unfit, and have left, therefore, only the freshmen and sophomores, the greater part of whom are under twenty-one years of age, is it necessary for them to change, or is it not advisable for them to change, their courses of study in order to fit these men for the actual things they may have to do after they go into the army? It has seemed to some of us as though we ought to do this; that is to say, that if we know our courses in the engineering colleges are to be limited to two years, that we ought to materially change our courses of study during those two years in order to fit the men for some of the engineering work which it would be possible for them to do.

In conclusion, I would say that the engineering colleges have tried to look at this matter in an entirely unselfish way. They are not thinking of the number of students they will have, or of any income which will come from these students, but only of the question of the most efficient way in which they can train these young fellows for service, and they are ready to do anything which the Government wishes them to do in order to carry out this plan.

THE OPPORTUNITY FOR INDUSTRIAL RESEARCH

By C. E. Skinner,[1] Pittsburgh, Pa.

THE successes of the past and the host of problems awaiting future solution should be ample proof that industrial research has before it a field of unlimited opportunity. There are many phases of the subject which might be discussed to advantage at this time, such as the extent to which industry should carry on pure scientific research, the extent to which different industries could pool their research interests, methods of attacking research problems, the education of research workers, the coördination of industrial, governmental and university research, and others. This paper will, however, be confined mainly to an attempt to show by illustration some of the opportunities which exist. Possibly no better example could be chosen than that of the study of alloys, and this should appeal to the mechanical engineer as no other single development has perhaps contributed so much to his progress in the last two decades. Machine tools have been revolutionized. There are few important machines today which do not depend on alloys for some of their vital parts. The automobile, the airplane, the modern locomotive, dynamo-electric machinery, and many others, would require changes much to their detriment if modern alloys were not available.

And yet, in spite of the work already done on alloys, we have explored but a fraction of the really useful fields. Few, if any, general surveys have been made of the possibilities of binary and ternary combinations, and such studies should yield results of great value. The subject might be attacked in either of two ways: first, by endeavoring to get at the fundamental laws governing the alloying of metals so that the results of making any particular combination could be predicted; or, second, by experimental methods actually making and testing a sufficient number of the alloys under consideration to give the data essential. The purpose of such a study may be to produce an alloy with certain desired characteristics for a specific purpose or it may be to determine the useful alloys possible from the combination of any two or more metals. The former may be relatively easy or very difficult, depending upon the requirements. The latter cannot fail to be anything but difficult and long-drawn-out, no matter what the method of attack. Let us consider briefly what such a survey means. It would be desirable to start with chemically pure metals, but metals chemically pure are practically unknown and often metals of a purity not at present commercially obtainable show characteristics very different from those commercially obtainable. For example, magnesium as ordinarily obtained is quite brittle, while the metal approaching chemical purity is very ductile. Tin of high grade combined with lead gives us a solder with well-known characteristics, while certain commercial tins now on the market carrying small percentages of bismuth impart to solder characteristics markedly different from the purer tin. Consequently natural impurities must be studied both as to their influence and as to their elimination. Methods for the preparation of the constituent metals with unusual purity must be developed. The differences between the effect of natural impurities and added impurities must also be examined, as these differences are sometimes very marked; as in the well-known effect of added sulphur as compared to natural sulphur in steel for certain purposes.

Keeping in mind the necessity for pure materials and the influence of impurities and alloying methods, we may assume that a series of alloys of any two metals is to be made varying in their proportions by 1 per cent. This would give us ninety-nine different alloys for each grade of each of these two metals. Each of these will require a large number of tests and repetitions to determine the various influences which may change their important characteristics, and each sample will require a large number of determinations to arrive at its chemical, physical, electrical, magnetic, thermoelectric and other characteristics. It may be necessary to study the effect of each natural impurity on each alloy of the series, which will multiply the tests manyfold. Those which promise to be commercial will require many further tests to determine their working qualities and adaptability to commercial uses. In addition to the above, it is well known that certain alloys have very sharp and very marked inflections in certain of their characteristic curves, sometimes within a range of less than 1 per cent variation in their composition, as, for example, the variation in the thermoelectric value of certain nickel-iron alloys which occurs at approximately 27 per cent nickel.

Such a study even of a single series of binary alloys would involve tens of thousands of determinations and much time and expense. If we add a third and a fourth alloying metal, it will readily be seen that a lifetime would be entirely too short to compass a full exploration of such a series. In fact, it is doubtful whether a relatively complete study of the possibilities of a single binary combination could be accomplished by any one in an ordinary lifetime. A very elaborate study of the single alloy, 88 per cent copper, 10 per cent tin and 2 per cent zinc, has been under way for two or three years, the leader in this work being the Bureau of Standards, assisted by a number of producers and users of this material. The Bureau has outlined over a score of characteristics to be determined and the work is as yet far from complete.

It may be argued that such an elaborate study would not be warranted even to give complete data, as many zones could be passed by as not promising or a few experiments at most prove that the combinations in certain zones were of little or no commercial value, but we are learning that where ordinary methods with metals of commercial purity fail to give useful results, other methods or purer materials may give results of great value. Unfortunately, we do not know the theory of alloying well enough to predict results with any certainty. We know of no theory to account for the fact that an alloy of 3¼ per cent nickel with iron has low permeability at low inductions and high permeability at high inductions, while an alloy of 33 per cent nickel with iron has high permeability at low inductions and low permeability at high inductions, and an alloy of 27 per cent nickel with iron is totally non-magnetic, except at very low temperatures. Or again, how shall we account for the fact that certain alloys of copper, aluminum and manganese, where all the constituents are non-magnetic, produce an alloy which is strongly magnetic, while an alloy of 12 per cent manganese with iron—the latter being our most strongly magnetic material—gives an alloy which is non-magnetic. Again, alloys of aluminum and tin, with or without

[1] Research Engineer, Westinghouse Electric and Manufacturing Company.

other alloying metals, may make alloys with fine characteristics when first smelted, only to disintegrate to powder later. No satisfactory explanation for this action is now available. These phenomena are just as difficult to explain as the fact that two gases, hydrogen and oxygen, combined in a certain proportion give a liquid (water), while three materials, carbon, hydrogen and oxygen—the one a solid, the others gases—when combined in certain proportions give a resulting gas, in other proportions a liquid, and in still others a solid. The idiosyncrasies of certain alloys cited above show the futility of attempting to predict results with our present theoretical knowledge of the subject. It is probable that the necessary theory for a full understanding of the subject may come only from a study of the atom—its structure, its combination into molecules and the ultimate forms and characteristics which the constituent elements may take. A general solution will hardly be possible from a study of the chemistry or the metallurgy of the subject, but by a coördination of the chemistry, the metallurgy, the physics and the magnetics through the work of the molecular physicist. Thus the ultimate solution of a very practical industrial problem can hardly be expected, except through the work of the pure scientist. True, the patient experimenter trying to explore the whole field may furnish the facts to prove the theory conceived by some brilliant mind, which will make further drudgery in this line largely unnecessary.

The above example has been dwelt upon at some length to show the possibilities of unlimited research in what might seem from a superficial examination to be a highly restricted field. This is equally true in numbers of other fields. We know very little of the laws governing insulation and the theory of conduction in dielectrics. It is possible that the fundamental laws governing the characteristics of alloys may also explain some of the mysteries of dielectrics.

The examples cited illustrate another phase of the subject that may be emphasized to advantage, and that is the ever-widening field of any research, no matter how restricted in scope its object may be. The study of a single series of binary alloys may necessitate studies in the source and preparation of the raw materials, methods of smelting and alloying, a study of containers and molds for the molten metal, types of furnaces, temperature measuring devices, smelting and pouring temperatures, rates of cooling, effect of quenching, methods of forging, rolling and drawing, development of new test methods to determine new characteristics and many other phases of the subject. Totally new characteristics may be found by using hitherto untried methods; for example, alloying under extreme pressure or temperature, or both. If the worker is to understand fundamental laws governing the work which he is undertaking he must have a thorough knowledge of the chemistry, physics, mechanics and magnetics or he must have co-workers available who can look after such phases of the subject together with the necessary equipment for carrying on the necessary tests.

Compares Nation to Alloy

If this country is the melting pot, then this nation is an alloy, an alloy infinitely more complicated than any I have described. What are the influences for good? what are the poisons? what evil influences can be fluxed off in the smelting? what will remain to vitiate the resultant alloy? what will be the result of the heat treatment of war? will it respond to the new treatment necessary after the war? What a research we have before us as engineers and citizens!

No paper on research today is quite complete without some reference to the war. Prior to the war some one decried research and scientific development generally, because of the possibility of their making war more horrible when war should come, and many felt that war would become so horrible as to be impossible. We must admit that much of the horror of the present world war which particularly appeals to our imagination has been made possible through our latter-day research and scientific development. We have but to refer to the submarine, the airship, noxious gases and high explosives to illustrate the point. It is doubtful, however, if any right-minded man would wish that all development through research should have been halted at any previous specified time, in order that the use of such things should be impossible. We would not give up our advances in chemistry in order that high explosives and noxious gases could not be used. We would not discard the telephone in order that the submarine could not be provided with listening ears. We would not discard our advantages in aeronautics in order to prevent the dropping of bombs on defenseless women and children. Each element of frightfulness based on scientific research can and must be met and conquered by scientific research. The agents of frightfulness and the means of overcoming them will become the means of restoration and reconstruction after the war. The "die is cast" and we must go forward with our research as never before, both to win the war and to provide for the readjustment necessary after the war. We are spending our natural resources at an appalling rate, but we must use the last pound of coal and the last drop of gasoline, if necessary, to win the war. If this be necessary, we must find other substitutes through research. The development and use of the internal-combustion engine has reached a stage which makes it impossible to think of the world after the war without internal-combustion engines, even though our present fuel for them be exhausted. Furthermore, the restrictions imposed by the war have taught us that many substitutes are possible where such substitutes would have been considered impossible or at least very undesirable before the war. Tin-base bearing metals were considered absolutely necessary for some services until the scarcity of tin made it necessary to use a substitute containing little or no tin, and this has been perfected until it meets every service equally as well as the genuine babbitt.

Research Necessary to Win War

We cannot emphasize too strongly the two main points brought forward in this paper: first, the unlimited field open to research in every conceivable line of endeavor, and, second, the necessity of taking advantage of these fields both to win the war and to provide for the reconstruction and readjustment that must follow. Research can and must do its bit now. Research can and must be an important factor later. To meet these requirements we need workers trained in the fundamentals of all branches of science who can bring to their work the devotion, the enthusiasm, the optimism and the imagination so essential to success in any work and doubly so in research. We need the aid of all who can help in the training of research men. We especially need the aid of men with imagination who are in a position to furnish the funds, the equipment and the organization to provide that pure science and applied science shall advance in every possible way. It is not hard to show that industrial research through applied science pays. It should not be difficult to show that this depends on pure science and, therefore, that pure science should pay in every sense of the word.

THE AGRICULTURAL PROBLEM

By LIBERTY H. BAILEY,[1] ITHACA, N. Y.

(Abstract)

I AM here by telegraphic order, standing in another man's shoes to discuss his subject, yet without having his paper. All I can hope to do is to establish a point of view. If I were to make any statements on the place and office of engineers in the body politic, I should want first to attend their meetings for some time and also to associate with them in their professional capacity in order that I might see something of their problems in their public relations and also understand their own measurement of themselves. You deal with mechanical or physical forces. It is your business to handle these forces and to make them serve you in a large way. It is one of your problems to eliminate time and space as they apply to the ordinary man. You are dealing with large affairs, with persons in the mass, and with work that has distinct public relations.

There are those, however, who deal primarily with biological forces. The forms of life are adapted to the conditions in which they are placed. It is not necessary to inquire here what has been the process of this adaptation, but all biologists recognize as a starting point of their discussions that the animals and plants are adjusted to the conditions in which they live. Today I invite your attention to this situation, asking you for the moment to forget as far as possible the physical and mechanical relations in which you customarily deal.

Farmer's Attitude in War

Just now we hear much about the farmer's attitude toward the great affairs confronting us. There is considerable criticism. All the criticisms I have heard are projected from the point of view either of class organization or industrial organization. Those who would defend the farmer speak of his psychology and the necessity that the rest of us understand it. The result is that much of the treatment of the farmer is cajolery. The situation lies far deeper than psychology. Let me give you a formula:

"The farmer is part of his environment, matching himself into his background, perhaps unconsciously, much as a bird is matched, or a tree, or a quadruped. His plan of operation, his farm management, is an expression of his situation in nature: he has worked it out because it fits. He cannot shift it radically to meet the advice of any other person. As he himself develops in ability he will modify his plan of operation so far as he can, but the plan must always fit his place in the environment; no great change is possible unless his natural conditions change: he does not make his conditions. The farmer exemplifies, in the human range, what the naturalist knows as "adaptation." His situation does not admit of compromises, perhaps not even of adjustment, and therefore it may not be understood by teachers, publicists, officials."

Farmer Cannot be Pressed

The consequences of this formula, if it is true, are tremendous. All the advice given the farmer that does not recognize his necessary adaptation to his environment is useless; and useless advice is harmful. It is of no advantage to rail against the farmer any more than against the wind or the rain. It is idle to try to apply to him the pressures that are exerted on corporate business. It is of small consequence either to praise him or to condemn, to take sides for him or against him, except insofar as it may affect his spirit as a man. When, under pressure of great crises, we radically change the conditions under which the farmer works, we must allow him time to readjust himself: he must take account of the latitude that he may reasonably expect in weather and soil and human forces. He needs not favors, but conditions that will allow him to operate. The natural conditions within which he works cannot be changed, but they can be modified in some ways, and he can make new adjustments within certain limits; these possibilities he begins to understand, and they are parts of his problem as a farmer; when the economic or outside conditions are changed, the modifications must be such as will match the natural limitations, if he is expected to adopt them. In the present crisis our public agencies must understand and recognize what can reasonably be required of the farmer.

It is an old adage that appearances are deceitful. I wish to add that they may be misleading. Persons managing corporate, industrial, labor and professional affairs have a certain air and habit of presentation. The farmer operating his farm may not have this air. He has nothing to present. He may be following a plow in the back lot, unshaven, trousers in his boots, working until the work is done, even though the clock points to five. Perhaps he would not discuss politics or civics or religion, at least not till he knew you; but, good or bad, he has worked out the management of his farm, and he thinks he knows why. He will listen to your advice; then he will go on with his plowing. He is hard against facts—real facts, not paper facts; he accepts them and acts accordingly. You may not like him, but he himself is a fact.

Attitudes Toward Farmer Ridiculous

Bearing in mind these fundamental considerations, established in the nature of things, some of the popular attitudes toward the farmer become ridiculous. I was out of the country when war was proclaimed, but I understand that everybody who had a public voice fell to advising the farmer. This is futile, since the farmer is the one part in the population to whom advice of this nature is of no value, and for the reason that it cannot be applied. I am sure that much of this advice made no account of situations that neither the farmer nor any one else can change. Such advice is not only vain, but it works mischief. The farmer fails to accept the advice not because he is unwilling, but because he cannot. It is suggestive that every person thinks he can advise the farmer in his occupation; it is significant that the farmer does not undertake to advise other occupations and professions.

It is simple enough to change an outside or commercial condition in relation to the farming occupation; it is quite another matter to expect the farmer to accept it unless other essential conditions are changed to meet it. Fixing the price of any product, while it may be necessary in times of crises, does not add fertility to the land, or modify the weather, or affect the habits of a sheep or a horse or the requirements of a herd of swine. To say that a billion dollars is to be added to the income of farmers by war prices means nothing, unless we have at the same time a statement of outgo. To say that the increased gross value of farm products of 1917 over 1914 represents war profits is to state only one factor in a transaction, and to state it loosely. To advise the use of less milk in order to save it does not take the cow into consideration; the cow is not a machine that can be stopped by turning off the steam and discharging the operator.

[1] Professor Emeritus, Agricultural College, Cornell University.

To establish any regulation touching production on a basis of compromise or agreement between contending parties does not take into consideration the fundamental problems on which the regulation must rest for its operation. This is well expressed in Warren's recent statement following a long hearing on the cost of milk, that there is no known way of making a cow produce milk by argument.

The political method, which is the method of compromise or expediency, cannot change a single fundamental fact in agriculture.

Is the Farmer Profiteering?

You understand that I am not defending the farmer—his acts are as much open to review as those of any other citizen—I am merely stating his natural situation. As illustration, let me refer to the recent charge that he is profiteering. The farmer does not make profit in the commercial sense, but only a labor income. Now and then a farmer may buy and sell without producing, or even speculate, but this is not farming. The producing farmer does not become "rich" in the commercial sense. His occupation yields only the returns from his work. His overplus is likely to go back into the land, and the next generation has the benefit.

One of the most amusing statements I have heard is that reported of an influential financier to the effect that we must now take the farmer in hand and control him. The idea is that the farmer is becoming too powerful and makes too many demands. Now, for the past ten years or more public men have been advising the farmers to organize for protection, and the farming people have been shown the results that have been won by organized labor and industry; yet as soon as the farmer begins to use this dangerous weapon, a shout of alarm goes up from those who have advised it. If the farmer anywhere uses the weapon of organization, he only follows the precedent of industry and commerce. This is to say that the weapons of industry and commerce are then turned against themselves. The present mood to discipline the farmer is but another expression of the old disposition—so old as to be automatic—that the farmer must be kept where he belongs.

Agriculture Very Little Organized

In fact, however, agriculture is yet very little organized commercially or politically. Former attempts have failed. We are watching the two movements now before us with new interest; it is yet too early to measure their accomplishments. It is now charged that farmers are withholding the sowing of wheat in order to hold up the prices. In the first place, there is no organization of farmers that can control the wheat situation; and if any number of individuals reduced their own production they would be playing into the hands of the heavier producers or of handlers. It is impossible for farmers to control their production as manufacturers control their output. Whether a man sows more or fewer acres of wheat, he does not know what his crop will be: the unpredictable conditions that make the wheat crop are too many.

Organization for commercial offense, or even for defense, is indeed a dangerous weapon. It is dangerous in itself; it is dangerous because it forces government into compromises, and also because it relieves government of its plain obligations; it is dangerous because it sets one part of society against another. In agriculture it is specially dangerous: it has here all the danger that it has in any other realm, and, besides, it cannot change a single natural condition.

[Having laid down these general statements, the speaker illustrated by calling attention to advice that is likely to be given the farmer and which cannot be applied because it does not fit. He spoke about plans for doubling the produce of the poultry yards and other stock, bringing out the fact that this requires more feed, and that this feed cannot be fed to livestock and to humans and certain parts of it sent to the Allies at the same time. To talk about doubling the output easily in poultry or some other special line under the limitation and conditions that are now apparent may be little more than nonsense. He also spoke of the fallacy of trying to secure more beef by allowing the veals to grow up. Veal is practically a product of the dairy regions, and the only reason for desiring calves is that the cows may freshen. If these calves are all kept for beef, then they will compete with the cows for feed and labor and the dairy business will greatly suffer. Recent studies have shown that possibly one way to increase the supply of meat is to kill the veals earlier rather than later, so far as it can be done within the law.—Editor.]

Food and the Labor Problem

The food problem is now on us with staggering force. Fighting men, munitions and similar supplies, and food, are the fundamental or essential materials in the prosecution of the war. We now face the problem of supporting vast armies in a foreign land, making good the losses by land and by sea, and supplying the needs of millions of allied and neutral peoples. We are to expect that the problem will increase in magnitude. Never has a people been presented with a food problem of such stupendous proportions.

At the outset we are to face the contingency of the probability of a lessened yield. In the three war years the yields of the staple grains have been heavy. Only five times previously in the last twenty years have they been as great. This fluctuation is due, to a great extent, to unpredictable conditions of weather and climate. In two of the years the yields have been very low, and if very untoward conditions should arise next year, it is well within the range of possibilities that disastrously low yields might result, although they are not expected. We must take every precaution, therefore, to reduce all the elements of chance that are reducible in order to safeguard the situation and to secure a food supply as nearly adequate to the situation as possible. We are already applying these cautions effectively.

The labor condition may prove to be the key to the problem. Farm laborers and farm operators both are involved. They have volunteered; they have been drawn off by the great industrial demands, receiving wages that food production cannot pay; they have been drafted. The situation is not to be met by argument or by any array of tabulated figures. The actual experience of the farming people the country over must be accepted as true. The farmers also must coöperate to the full.

Farmers should not be exempted as farmers, for exemption is not a class interest. Yet we must save the energies of the people for the production of food as well as for other war purposes. Some of the harvest of food may be accomplished by volunteers, young and old, sent to the rural districts when emergencies arise; this, however, affords no solution of the regular and steady application that is needed on the land, a need that is now greatly increased. The producing of food, as the producing of anything else, needs dependable and experienced labor; food production needs farm labor rather than city labor.

Four Requisite Food Regulations

The food production is not to be maintained by the ordinary processes of economic regulation, particularly when the law of supply and demand is so much interfered with or even abrogated. Many movements and activities will influence the production, but four are of paramount importance.

1 We must save the food. This saving is not only economizing in the use of it, whereby we reduce the waste, but quite as much in the redirection of the diet and the reconsideration of the family activities. Fundamental changes are to take place herein if the war continues any length of time. To every person in the land, to every family, to every hotel and club, to every social organization, the call must come to consider whether the present eating habits are either sound in themselves or patriotic. Not only does the question of wheatless and beefless days seem to be involved, but that of better dietetics as well.

2 We must save labor. Extensive activities employing labor; perhaps whole industries must be stayed; perhaps some of them should never be revived. If we eliminate the useless and also the unessential, we shall be able to release much labor. The simplifying of the household scheme will also liberate woman labor for industries and farms; we shall need it all. If the war long continues women must take the places of men in countless industries where heretofore only men have been employed.

3 We must grow more food on the small home properties in city and town and suburb. This is not farming, for the householder does not maintain himself and family by the raising of supplies. This activity is justifiable only so far as the operator does not demand labor that can be used elsewhere. Himself and members of his family and household establishment should do the work. There may be many failures and disappointments; but there is no charge for labor. What energy one puts into the raising of food is likely to be deflected from less patriotic uses. Much foolishness is displayed in some of these home food gardens and in some of the semi-public enterprises of this kind. I hope that something has been learned this year. We may expect better results next year, even if the gardens should be fewer. We shall learn to grow the dependable things, few in number, and those that can be utilized to best advantage in the family. Great secondary and civic gains will result from this tilling of the land by the sweat of the face. Yet, with all that can be accomplished in the making of home gardens, we shall not affect the production of the great staples, as the breadstuffs and the red meats; but we may relieve ourselves of the necessity of using so heavily of these staples, thereby saving them for export.

4 We must directly increase production on farms. To this end we must establish food production on a wartime basis, giving it the best economic protection and the directest aids. Here lies the great remedy. The major strategy of the nation having been determined, we must then apportion and distribute the activities of the people toward the accomplishment of the one result. No industries or activities should be allowed to proceed at the expense of munition making and food production, or with the distribution of them, or any part to work to the disadvantage of another part: all the parts make the whole. The entire people now makes war. The war is one problem. If by stimulation, oversight and regulation the food situation cannot be met, then men must be assigned to farms as definitely as they are assigned to armies.

North America is the last defense in the food support of the war.

THE FUEL PROBLEM

By Prof. L. P. Breckenridge, New Haven, Conn.

Precisely stated, the fuel problem is that the coal bin of the United States is not full. How much do we need to fill it? One hundred million tons. Can we get it? We will try to produce more coal. We may produce fifty million more than we have ever produced, but we shall have to save another fifty million.

If you will build a coal bin 1000 feet on each side, that coal bin will have to be 4½ miles high to hold the coal which must be mined this year in the United States. That is a good-sized coal bin, higher than any mountain in the United States, and it takes a good deal to fill it, but if everybody saves a little coal we will save fifty million tons.

The question of the fuel problem is divided into three parts: the production of coal, the distribution of coal, and the use of coal.

In connection with the subject of production, Dr. Noyes, of the Fuel Administration Department, says that there is no use of producing coal—taking it out of the mines and piling it around the mouth of the mine. It is better to go down into the mine and get it with the machinery available than to raise it when there are no cars to put it in. If that is so, and it seems entirely probable, the coal in the mine is ready to be taken out and is being taken out as fast as cars are put there to receive it.

The railroads of this country distribute a large proportion of our coal, about 85 per cent, and nearly 35 per cent of the entire freight they haul is coal. No wonder we would like to fill the coal bin just to have the coal, but we would like also to get rid of the job of hauling it. We need the railroads for other things, not only for hauling food, but for materials which go into munitions. The problem of distribution is after all one of the most serious problems in connection with the fuel problem at this moment.

The problem of the use of coal divides itself very naturally into two parts: First, if we are to use coal we should use it with economy; second, will the time come when it will be necessary to limit the supply of coal to certain industries? If we are careful of the coal we possess that will not be necessary; but if we are not, there will have to be some priority of use of coal.

It is preëminently the function of the engineer to use coal with economy. During the entire period of this Society's existence, 38 years, I doubt if there has been a meeting when papers were not presented which referred to the economical burning of coal, or the economical use of steam, or the economical use of electricity. They are one and the same thing, as we burn coal to make steam, to make power, or, as a secondary product, the electrical energy which is to be distributed for power and lighting uses.

Sixty-seven per cent of all the coal produced is used to make steam. The steam is not all for power purposes, however, part of it going for heating. But this use of 67 per cent of the coal production shows the desirableness of using economy, and saving a lot of this coal by saving steam, and by saving the power we make from steam.

The United States, Great Britain and Germany produce the coal of the world, the world's production now reaching about 1,600,000,000 tons.

In the United States we mine, speaking broadly, two kinds of coal, anthracite and bituminous. All of our anthracite coal comes from Pennsylvania, from Scranton, Wilkes-Barre and vicinity, and we have never yet produced 100,000,000 tons a

year. In the rest of the country we get bituminous coal, which varies much in its composition. We get most of it from Pennsylvania and West Virginia, a lot from Illinois, and a little from the lignite fields west of the Mississippi. We are producing bituminous coal in increasing amounts, and will mine close to 600,000,000 tons this year.

Anthracite coal becomes more valuable in the ground next year, and we have only enough to last perhaps one hundred

years. Our bituminous coal will last us 1500 years, according to Geological Survey estimates. A few slides are now in order.

Fig. 1 shows the coal production at each ten-year interval in the United States, beginning in 1800. Up to 1885, about the time this Society was formed, we had not mined in this country as much as was our increased production in the last ten years.

Fig. 2 shows the states which produce coal, Fig. 3 those which use anthracite, and Fig. 4 those using bituminous. This year I think the railroads alone are using 145,000,000 tons, and will need, and must have, perhaps, more.

Fig. 5 shows the proportion of bituminous and anthracite coal used by the various states. The railroads only use a very little anthracite compared with bituminous. Illinois uses only a small amount of anthracite. Ohio uses a very small amount of anthracite, less than the city of New Haven. New England uses more bituminous than anthracite.

Fig. 6 shows the coal consumption by industries. Fig. 7 shows the per capita consumption in various sections of the country. In the Pacific Coast states the consumption is only about one-third of a ton per capita—they use hydroelectric power and burn oil in their steam power plants, and as the winters are mild they do not use much for the purpose of keeping warm.

The fuel administration has a coal-conservation department, in charge of Dr. Noyes, and his activities reach to every state where there is a fuel administrator. The Bureau of Mines, augmented by a committee appointed by the four national engineering societies, is acting as technical adviser to this conservation department. The various engineering societies can give much help to this question of conservation in their own localities, and it would seem they should coöperate with the fuel administrator in their particular locality.

The United States Chamber of Commerce, having connections with 950 cities in America, is issuing from time to time valuable information bearing on this subject, and its committee on coal conservation has invited Dr. Hollis to appoint a number of engineers to sit with them; and so they are helping in that way. In many of the state fuel administration offices we have engineers working with them to help save coal.

MOTOR-TRUCK TRANSPORTATION

By William P. Kennedy,[1] New York, N. Y.

Motor-truck transportation has now become firmly established in military and commercial service, and the purpose of this paper is to point out the developments to be expected from our immediate necessities created by the existing condition of war.

There are three stages to the introduction and development of most of our industrial utilities; first, the pioneer stage in which the designer and producer bring the apparatus in question to a condition where it can be practically employed as an economic device; in this stage there is a period during which considerable missionary work must be done to induce the prospective user to recognize its economic advantages. The next or second stage is that in which the apparatus is used in a preliminary way, during which period the user becomes gradually familiar with the possible accomplishments of the device and begins to have confidence in its commercial value, by being able to satisfy himself definitely of the reduced expense or increased performance which he is actually gaining by its employment. The third and last stage is that in which the device becomes a competitive necessity in the hands of the user, due to its general employment in commercial service. In rare instances the coming of this stage may be hastened by some extraordinary situation in which the failure of existing means for performing equivalent service forces the employment of the new device as a necessary substitute.

In the development of the use of motor-truck transportation we have now reached the beginning of the third stage, just described, and are confronted with a situation where the older means of transportation is so overcrowded and congested as to demand the immediate and general use of the motor truck as an urgent expedient for relief. Our general situation therefore at the present time of congested rail and water transportation may be the greatest possible boom that could exist for a very extensive development of highway transportation, by means of the motor truck. This development during the next year or two will probably be the equivalent of that which would gradually take place over a period of twenty-five years under normal circumstances.

As indicated above, the reliability and economic value of the motor truck is already established. The employment of these machines to the number of 300,000 throughout the country in commercial service is sufficient proof of this. In its application to military requirements there has been a more rapid and conspicuously successful development, as is evident by their numbers and the character of their service in the various zones of military activity in Europe, as well as the great quantity employed for military requirements at the home base of each of the belligerent nations.

While the motor truck cannot be regarded as having created any revolutionary change in methods of warfare, the effective character of its service, wherever time has been an important element, has had a marked influence in speeding up military operations. It has consequently found its place as an indispensable adjunct in military equipment, from which it can never be displaced and in which its usefulness will continue to extend. The motor truck has provided the army with other utilities beyond road transportation of munitions and supplies, in furnishing the speedy ambulance, the scouting armored car, the mobile gun, the powerful caterpillar tractor, and finally the tank as a formidable fighting machine.

There may be lines of demarcation as to the limitations of the motor truck in military field service between the railroad in the rear and the army mule at the front, but its permanency and usefulness in between these limits is unquestioned. The extension of its application in overlapping the service of the railroad and superceding the army mule has been demonstrated in many occasions of emergency, and it is therefore likely to continue forcing its value in both directions as its superiority becomes more frequently demonstrated in cases of actual necessity.

The motor truck is already so well entrenched in military service that our Government has been abundantly supplying itself with many thousands of these machines. It has been able to take advantage of the experience of other nations engaged for a longer period in the conflict to furnish itself with the most suitable equipment which the industry could provide as its regular commercial products. It has gone a step further in securing through the collective coöperation of the engineering ability of the industry several special types of motor trucks, the design of which is based upon the accumulated experience of three years of vigorous warfare; while the industry in the few years of its rapid growth has become so substantial that the emergency requirements of 30,000 to 50,000 motor trucks can be furnished almost as a matter of course, and without any serious impediment of the routine conduct of its business.

Our immediate interest is now concentrated not upon these past accomplishments, but in a determination of what are to be the demands of the near future in furnishing domestic highway transportation to aid in conveying, from our scattered centers of production to our seaport terminals, the vast quantities of supplies and munitions required to maintain from

[1] Consulting Engineer.

one million to five million men in the field in a foreign country.

We have already in evidence the limitations of our old-line means of rail and water transportation, and although vigorous steps are being taken to find satisfactory remedies for their congested condition, the problem of making these already overworked facilities conform to our increasing necessities is an extremely difficult and complicated one. The situation calls for extraordinary activity and extraordinary methods in finding its solution, and one of the principal factors which will develop as an element in the solution of this great problem will be the employment of motor-truck trains in scheduled operation over our principal highways.

The producer, merchant and consumer of materials requiring transportation from one place to another throughout the country have become so habitually shackled to the limitations of our railway and waterway transportation facilities that it is extremely difficult for the prosaic commercial mind to release itself from its accustomed methods and to rise up and find a new and efficient means of relief. It will probably require the superior genius of the military mind in its capacity for meeting emergencies, coupled with the resources which military organization provides, to take preliminary and effective steps toward making use of the motor truck and the highway to offset the limitations imposed by our older transportation systems.

Fortunately, the situation has all the elements which can possibly contribute to success practically lying at hand waiting to be utilized; and the only thing remaining to accomplish the purpose required is the necessary authority with a competent executive or administrative organization to put into actual operation road motor trains adjacent to all the centers where freight congestion now exists.

The ability of the motor truck as an individual operating unit or as a tractor coupled to trailer equipment has been well demonstrated under a great variety of operating difficulties throughout the country. All the highways in the country may not be fit for transportation of this kind, but over the comparatively limited number of routes where the operation of such motor trains would be required the conditioning of highways is either an accomplished fact at present or could be made so with little difficulty or loss of time, by making use of the facilities which most of the state highway organizations have at their command and are ready to supply for such emergency requirements almost immediately upon notice to do so.

In the present-day motor truck, backed by the brains and facilities of one of the greatest industries ever developed, we have the means for providing transportation equipment with which we can accomplish extraordinary service. For several years past the manufacturers of motor trucks, under the stress of keen business competition among themselves, have developed the machines produced to a point where they are capable of performing almost any task allotted to them. Aside from their normal functions of transporting freight, they are in many instances called upon to perform a great variety of military service incidental to transportation. In some cases their equipments constitute portable power plants for performing service of some distinct character, such as that required in lodging and mining camps. They occasionally furnish lighting. Frequently they perform loading and unloading operations, such as the hoisting and dumping of coal bodies, or the removal and replacement of separate bodies which have been loaded while the truck itself has been absent on its delivery route. In fire-fighting service they are practically replacing the old line of equipment, and a special type of motor truck has been developed which is now regularly known as a road builder, hundreds of which are doing marvelous work in the rapid development of our highways.

It will therefore be seen that under the intensive development of competitive motor-truck equipment the manufacturers have been prepared for just such emergency requirements as they are now likely to be called upon to meet, and therefore any organization which may be developed, either by the Government or by commercial institutions, to solve this problem of highway transportation will find the truck manufacturers perfectly competent to furnish quickly suitable machines in any capacity or number that may be required.

With this assurance as to an adequate supply of rolling stock, the next step in the project will be to put a few selected stretches of highway into serviceable condition and to keep them so.

Whenever the question of highway transportation has been considered in the past, the good-roads topic has always been introduced and discussed in terms which embrace the entire road system of the country and the magnitude of the task of putting this complete system into first-class shape is usually dwelt upon as an almost insuperable accomplishment. It requires, however, no very great analysis to bring out the fact that only a very small fraction of one per cent of the highways of the country would be required for the contemplated service of relieving our present congestion or expediting the movement of freight between the principal centers of production and our seaports. This being so, the facilities now available in each state for the construction and maintenance of its roadways, if concentrated intensively upon the few routes likely to be required for this character of service, could put them in excellent condition and keep them so with comparatively little effort and expense. Consequently, this project of bringing into existence organized highway transportation has none of the cumbersome impediments usually attendant upon railroad extension.

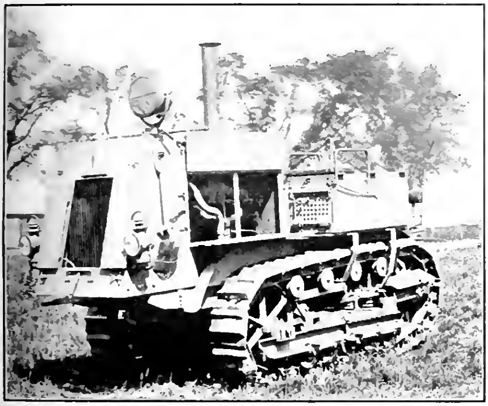
Many cases already exist where limited highway transportation is operated on schedule over definite routes. Many more systems would come into existence rapidly by virtue of their commercial value were it not for the fact that it is difficult to procure capital in large quantity for this kind of investment. One of the alleged reasons for this difficulty is the fact that the power of railroads has in the past been used to obstruct parallel competition of any kind, and this promotes the belief that if road-transportation operations were organized on a large scale the same influence would be felt in interfering with their development and prosperity. If this is really the case, then it will require initial steps on the part of the Government in such an emergency as the present one to put into extensive operation road-motor-transport service, and incidently prove its practicability and establish the permanency of such methods. Action of this kind should be advocated and strongly urged for the many advantages which would result from the spread of the use of this highway motor transportation. Its competitive influence would be a very valuable one to the public, as placing in the hands of producers and merchants their own independent facilities for limited freight movement would bring about marked economic changes in which all would be likely to benefit.

We should not be slow to take advantage of the lessons which have been taught us in this direction by France, England and Italy, in carrying into effect, almost immediately upon the opening of hostilities, road motor transportation upon an extended scale. Some cities and many of the small towns in these countries are almost entirely dependent upon

the motor truck as a means of conveyance, and the well-defined organization which has been brought into existence to maintain the equipments employed and to keep in condition the road surface required, are examples that should exercise a stimulating influence upon us to make advanced preparation towards meeting the more serious conditions which the increasing demand for transportation is likely to force upon us.

Discussion

George P. Hempstreet, in discussing Mr. Kennedy's paper, said that he wished to call attention for a moment to a peculiar state of affairs. We had one branch of the Government anxious to promote motor transportation, and had been assured that there was an ample supply of rolling stock available. In order to use that rolling stock it was necessary to have a highway to run it upon, the first requisite of which



45-hp. Holt Artillery Tractor with Armor Doors Open

was a sufficient foundation, generally of crushed stone or gravel.

Another department of the Government had issued Priority Order No. 2, which prohibited the shipment of gravel or crushed stone or anything to be used for road construction in open-top cars. Most of the quarries from which crushed stone was taken could only put their materials into open-top cars, as it was very difficult and expensive to use any other type of car, and very difficult to unload it.

The question might be asked, Why not use motor trucks? A motor truck could be used to haul a load of five tons, and if the load was worth $1,000 the $25 charge for hauling would not be very excessive. But if the load was only worth $2.50, a freight bill of $25 would be excessive and prohibitive.

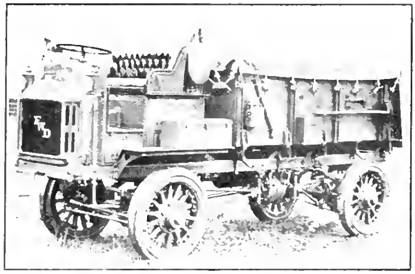
So we had one department of the Government which wished to have motor transportation and to use good roads, and another which was preventing their construction.

There had been every effort made to relieve freight congestion in the East by the use of motors to haul high-grade goods rather than use freight cars, but a branch of the Government was practically prohibiting the building of roads on which such motor trucks could be used.

ARMY TRANSPORTATION

By Major L. B. Moody,[1] Washington, D. C.

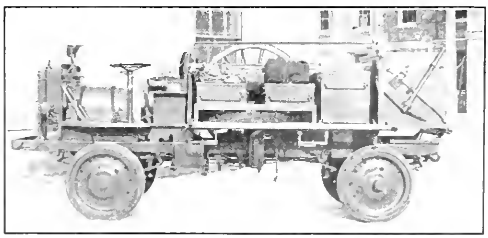
This question of army transportation is a pretty broad one, and in general it comprises very broad and distinct classes of service, all back of the fighting lines. When you go into the zone where troops are operating the first assumption is that there is no road, and also that transportation



All-Steel Ammunition Motor Truck Driving on All Four Wheels

becomes specialized, that is, the Medical Corps do not want their patients handled on the cubic-foot or pound-per-mile basis. Likewise, the engineers have special apparatus, such as portable searchlights and demolition equipment. The Signal Corps has its wireless outfit and equipment for their aeroplane service, etc. The Ordnance Department depends on the motor transportation, as it furnishes all the field guns and the materials known as munitions.

When the question of replacing the horse in this special service came up, it was referred to the Ordnance Department. There is no serious difficulty in replacing a horse where you have a road; but where you have no road and where you have got to be 100 per cent certain that you will arrive at your destination, that is where the difficulty of replacing the horse with the fighting troops has come in. That is, if the general supply trains fail on the main roads, it is possible that the men might go hungry for a day. But, if on the other hand



Jeffery Supply Truck for 4.7-in. Gun Battery

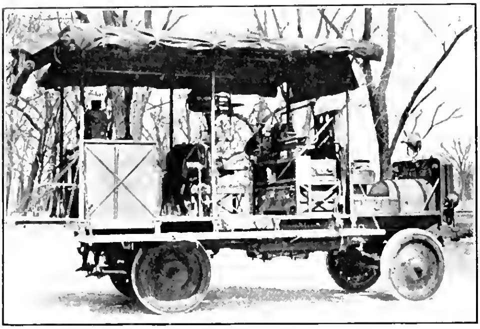
you wish to use a gun for a certain purpose, it is of no use to have it arrive a day late—it must be there on time. That has led to special forms of transportation.

As to the volume and the organization, it can be said that practically every gun handled by the United States Army will

[1] Carriage Division, Ordnance Department, U. S. A.

be handled by motor equipment, and if we get an army approximating in size those on the other side you will obtain some idea from the number of guns engaged of the magnitude to which this important matter of transportation has now grown.

I do not want to say our problems are solved, as they are not, but from operating the experimental equipment we had at the middle of April last, we have progressed from one officer in charge, a couple of officers, and a couple of draftsmen and five desks, to the point where we have schools turning out men to repair these trucks at the rate of 30 to 50 trained officers and several hundred trained men every month. We have estimated the number of men actually building these trucks (not counting those in related industries) and they number about 50,000. The number of officers actually on duty is from 300 to 400, the number of enlisted men runs into the thousands, all for repairs only.



Jeffery Repair Truck for 4.7-in. Gun. Drop Sides in Working Condition

The cost of this will exceed that of the Panama Canal, and the Ordnance Department has expanded something like forty times, by actual count, in the last eight months of its history.

We are endeavoring in the department to handle this problem ourselves, but we would have made but little progress but for the assistance received, particularly in my section of the Ordnance Department, primarily from the Society of Automobile Engineers, and from those among our officers who belong to The American Society of Mechanical Engineers or who would be eligible for membership. Without the assistance of these trained men it is safe to say that we would be nowhere.

[Major Moody then briefly described a number of views which he had projected on the screen, these views showing various forms of specialized motor transport, including ammunition trucks, a repair truck equipped with machine tools, an armored car, a tank, late forms of standard tractors used for hauling guns, a few of which are herewith reproduced. Four of the views were of unusually bad road conditions that could be successfully met by tractors, but in no case by horses. The facts that horses can be reached with poison gas and cannot be camouflaged as can the tractor, along with particulars regarding difficulties in ocean transportation, were given by the speaker as some of the reasons for the adoption of tractors.]

THE AIRCRAFT PROBLEM

By Dr. W. F. Durand, Washington, D. C.

It is perhaps fair to say that when hostilities were declared last April, no one at that time in connection with the Government had any vision of the part which the Air Service was destined to play in the plans which were soon to be developed. It is perhaps further fair to say that it was not until the visits to this country of the Balfour and Viviani-Joffre missions that these ideas began to crystallize into definite form. Very promptly, however, they did commence to so crystallize, and we began to get some vision of what the air service might possibly mean. Immediately there arose a series of the most important problems which have ever been presented to the United States and to her engineers in an engineering and industrial way.

I have jotted down a few of these problems, as follows:

1 Of the various types of machines, fighting, reconnaissance, bombing and training, what number shall be set as a goal for active service at one time?

2 What wastage in such machines is to be anticipated?

3 In consequence, what numbers in each type must we be prepared to build within a twelvemonth or any other specified time?

4 How many trained aviators will be required to maintain the desired number of machines in active service?

5 How many men must be put through preliminary training in order to secure the needful number of active aviators with the necessary reserves? Or, in other words, how much raw material must be handled in order to secure the necessary amount of finished product?

6 How many mechanics and repairmen will be needed to keep this fleet of airplanes in all classes up to "concert pitch," and ready for instant service at any time and at all times?

7 Where and how are we to undertake to build the number of airplanes indicated as necessary as the gross output, say for a year, in order to maintain the fleet continuously at proper strength? Or, put otherwise, we may perhaps well ask what is the maximum number of airplanes which can be built in those various classes in the United States, or by the United States, without undue disarrangement of either needful war industries and of the irreducible minimum of peace industries?

8 To what extent will further demands be placed on air productive capacity by demands of our allies in Europe for airplanes or engines in types which we may hope to produce with high economic efficiency? and to what extent may we expect to draw upon them for certain types—as, for example, the fighting scout—thus relieving the United States to some degree of attempting, at least at the start, to produce this final word in the evolution of fighting aircraft, as developed on the battlefields of Europe?

9 To what extent will the demands of our allies call for raw material, such in particular as airplane timber? Will the total demand exceed the presumable supply, and if so, to what substitutes may we turn?

In considering this question, certain conditions are obvious. There is no use of talking about an air service if the number is to be limited to hundreds. If we have any vision of the activity and efficiency of air service as now conceived, it must mean the production and operation of airplanes in large numbers, measured in units of thousands and not hundreds. We must therefore fix as a number, in order that it may have any significance in the problem, a number measured in thousands. If

we can say five thousand, it is well. If we can say more, it is better. There is no definite answer to this question; but we are committed to maintain airplanes, once we are under way, in many, many thousands.

Again, what wastage in such machines is to be expected? That is a matter of statistics, and the data for the accurate determination of the answer to this question are not available. The data are contradictory. We lack definite information as to the average life of machines. Under certain conditions one may continue in active service a month, a week, or perhaps a day. But machines do not fly every day; conditions of weather intervene, and of the 365 days of the year only a fraction of them will be available for the fighting machines on the front. So, taking the average, we get to the approximation that the effective life of the machine will be several weeks, possibly two or three or four months.

In consequence, what numbers in each type must we be prepared to build within a twelvemonth or any other specified time? This is tied up with the question, how many can we build? And the answer is the same. We must be prepared to build airplanes in thousands. We must be prepared to build a multiple of the number in active service at any one time. If we are to maintain 5000 airplanes in active service at one time we must be prepared to supply during the twelve months a multiple of three, or four, or five or six times that number.

How Many Aviators and Mechanics Do We Need?

Again, how many trained aviators will be required to maintain the desired number of machines in active service? Obviously, there must be one for each machine in service. With modern machines, carrying more than one man, we must maintain in active service more than one man in each machine. There has been a tendency not always to insist upon the capacity to handle the machine on the part of every man who goes up. A man may be a good observer without being a good pilot. But this is not a good ideal. We believe that no man should go up in a machine for any purpose whatever without his being able to pilot the machine; to manage the machine in case the regular pilot is injured or killed, and to bring the machine back within our own lines. That means there must be a number of men trained for auxiliary service, but with a given minimum of skill. It is obvious the number of men we must be able to turn out in the course of a twelvemonth must be measured in units of several thousands. Five thousand would be minimum, and we must look toward some multiple of such number.

With regard to the actual provision for meeting this requirement, it is perhaps proper to give some idea of the capacity of the schools now occupied in this particular work.

The first step in training an aviator is to give a brief course of eight weeks in the so-called ground school. This is a school intended for preliminary instruction, not including work in the air. It includes elementary instruction in the principles of flight; in the principles and operation of internal-combustion engines, meteorology, photography, scouting, machine-gun work, reconnaissance work, and comprises lectures, class work and laboratory exercises in these subjects. This course runs for eight weeks.

The course contemplates the feeding in at these institutions of twenty-five candidates per week, and the feeding through and graduation each week of whatever is left of the twenty-five, taking into account the wastage. Without wastage it would mean twenty-five per week for each school to go to the flying schools; and with eight schools there would be about two hundred cadets a week, or something of the order of ten thousand per year.

There would be, necessarily, a considerable wastage and perhaps not more than one-half of that number can be expected to realize an efficiency which will make them significant units in the program as time goes on.

The capacity of these schools could be multiplied, and such multiplication is now in process of development. There need be no ground of apprehension about training these men, assuming that we can obtain properly qualified young men, with the necessary personal, physical and mental characteristics such as are needful to enter into the composition of the bird man.

It is true that of men qualified for the last and highest degree, men whose nerves and muscular reactions are such as to make them react instinctively—as bird men—the number is small. But, on the other hand, every well-built, normally developed and endowed young man is able to develop a degree of skill adequate to render him an effective unit in one place or another in the air service, even if only a few reach the supreme excellence which we see in some of the specially trained airplane fighters.

The number of these engineering, technical and scientific schools can furthermore be multiplied two, three or four times, and the capacity of each can be multiplied perhaps by two, on the average, and we thus have abundant possibilities for the development of a very large amount of material for ultimate service in connection with the plans now in formation.

The number of mechanics and repairmen is again a matter of experience, and it is found that for every airplane there must be one specially skilled mechanician who will give his entire time to the maintenance of that particular machine; and for each group of twelve, twenty-four or thirty-six, there must be an additional number, and in the base supply depots and other points back of the line there must be others.

If we go back to the supply of gasoline and lubricating oil, and to the supply of elements of that character, we may greatly multiply the number of men necessary to maintain in a state of efficiency any one airplane. But stopping short with the number of men concerned with the machine itself, we must multiply the number of aircraft by three, four or five.

If we take into account the number of fliers contemplated and the number of mechanics and repairmen behind the line in one capacity or another, it results that the contemplated officers and personnel of the Signal Corps will exceed the entire standing army at the outbreak of the war.

How Will We Maintain Our Air Fleet?

The next question: Where and how are we to undertake to build the number of airplanes indicated as necessary as the gross output, say for a year, in order to maintain the fleet continuously at proper strength? Or, put otherwise, we may perhaps well ask what is the maximum number of airplanes which can be built in those various classes in the United States, or by the United States, without undue disarrangement of other needful war industries and of the irreducible minimum of peace industries?

Now this question No. 7 comes closest to us as engineers and men concerned with the industrial affairs of our country: Where and how are we to undertake to build the number of airplanes indicated as necessary as our gross output? Where

to find and now to develop the tremendous extension in the industry necessary to provide this enormous number of airplanes for immediate production? It means the development of an industry, highly trained and highly specialized—not, indeed, out of nothing, but out of very small beginnings. Perhaps I should say that it meant the crystallization of the elements of such an industry. And it was splendid that there were found shops, and trained personnel and equipment and organization for the production of airplanes, right in the automobile industry. It meant, nevertheless, an enormous extension in productive capacity beyond any vision which the wildest flight of imagination could have contemplated a few months ago.

Only a few weeks ago I was able to visit, by way of inspection, three of the principal centers of airplane production at the present time Dayton, Ohio; Detroit, Michigan, and Buffalo, New York. There we saw new factories which were either completed and occupied or on the point of occupancy, aggregating something like thirty-five to forty acres of ground area, to say nothing of the gallery space.

Furthermore, there was ready for immediate expansion perhaps twenty-five to forty per cent in addition. It is fair to say that early in the next year there will be occupied actively in the production of airplanes something like fifty acres of ground area, with their gallery space, which did not exist eight months ago. And this is without taking into consideration the automobile factories. Acres upon acres of area in existing automobile factories are running solely on airplanes and airplane parts; and we are just on the edge of a period of very large production.

The period which has elapsed since last June or July, when the present program began to crystallize into reasonably approximate and definite form, has been necessarily spent in measures of preparation for this tremendous program of expansion and industrial development. And we may certainly anticipate within a few months, say two or three at the latest, that this factory capacity will be actively occupied in turning out airplanes at the rate of at least several thousand per month. The precise number I hesitate to define more closely at this time.

What Further Demands Will Arise?

The remaining questions I will touch on more briefly. They are: To what extent will further demands be placed on air productive capacity by demands of our allies in Europe for airplanes or engines in types which we may hope to produce with high economic efficiency? and to what extent may we expect to draw upon them for certain types—as, for example, the fighting scout—thus relieving the United States, to some degree of attempting, at least at the start, to produce this final word in the evolution of fighting aircraft as developed on the battlefields of Europe?

The other one, the ninth, is: To what extent will the demands of our allies call for raw material, such, in particular, as airplane timber? Will the total demand exceed the presumable supply? and, if so, to what substitutes may we turn?

It is sure that the demands of the Allies will put to the test every bit of our productive capacity for airplane material. We are now making for them flying boats in large numbers, and they are looking more and more to us for the production of airplanes for the training of aviators. In fact, the nearest approach to the standardization of a definite type is the American type, for at least the American, Canadian and British services. And they are coming to look to us for other types as well, and for the production of airplane engines.

The demands for supplies are also at the limit of our productive capacity. The demand has been incessant for timber—spruce, spruce, and again spruce! Serious difficulties have been met with on the Pacific Coast in the way of supply, but on the whole the prospect seems to be improving.

Substitution of other woods has also been introduced in some measure, which, while they have different characteristics from spruce, yet give effective service. And then there are suggestions in the way of metal substitutes which seem to hold hopeful and interesting possibilities.

The Problems of Standardization

One of the questions which presented itself again and again, and aside from the questions of policy or program, a question which is vital to the engineer, is that of standardization—standardization of elements and standardization of types. I need not take your time with a statement of the advantages of standardization of parts used in large numbers.

The standardization of elements, such as screw threads and fastenings, has progressed very satisfactorily; and for general airplane parts much excellent work has been accomplished through the efforts made by the Society of Automotive Engineers. And there is to be held soon in London an International Standardization Congress to which this Society has been asked to send a representative, and I understand that this Society will have one of its eminent past-officers at this conference as its representative and at which we may anticipate a still further approach toward standardization by way of elements and parts.

The other problem relates to the standardization of types, but here is danger. It is necessary to standardize; but it is fatal to attempt to standardize a type too rigidly, because if we know anything at all from experience on the western front it is that a type has no longer begun to prove a measurable degree of success than it is put out of date by the appearance of some new and improved type; and so as the weeks go by one type comes along after another.

The entire program must be based on the expectation of displacing from time to time types which for production purposes may be standardized for the time being, but which cannot be kept in production too long after the development of more efficient types.

I have tried to visualize this as a tremendous stream of production. Parallel with this stream of production we must have likewise a stream of development, research, investigation and a program which is seeking to contact with the unknown and the new; developing, judging, testing and determining their technical characteristics and their adaptation to the conditions of active service. And so fast as new types and forms are developed and proven superior, just so fast must they be fed into the stream of production, taking the place of out-of-date forms. Only in this way can we maintain the types and forms in use at the front responsive to the advance in the science and art of airplane production, and responsive to the conditions at the front and which must determine the characteristics of the material to be supplied at the fighting front.

The So-Called Liberty Motor

I should not close my remarks without saying a word regarding the attempts to standardize the airplane motor. You are all familiar with the story of the design and development

of the so-called Liberty motor. I will not go into that at all. But you can appreciate the fact that of the various problems requiring standardization, that of the motor was one of the most important. The question was: Shall we copy outright a European motor? Shall we copy outright the best American motor? Shall we combine the best in American motors and make a new motor? or shall we combine the best in European motors? or shall we combine the best in European and American practice and call that the standard motor?

In effect, the latter was the program undertaken. Drawings of European airplane engines and to some extent actual engines were available in May and June when the characteristics of the Liberty motor were determined upon. The characteristics of the best in American practice were naturally present in the minds of the designers, and on the basis of this and the best information from Europe and this country, the determination of the characteristics of the Liberty engine was developed.

The first engines, as you will remember, were built in an astonishingly short period of time, a matter of twenty-eight days from the time two men sat down in a room at the Hotel Willard until a motor was set up, and two days later was ready for test at Washington.

Then there was the question of the anticipated "teething troubles." The motor has been taken to Pike's Peak and sent up the grade and tested at various altitudes; and while there have been varying reports in the public press in regard to this motor, I wish to say that the reports in some degree unfavorable which have emanated from certain sources have not been well founded. The motor has met and is meeting the full expectation of its designers. It has had, as every design is expected to have, minor difficulties and troubles, but not one of them has been fundamental to the motor itself, and they all readily admit of correction and removal; and means have been found for the improvement and correction of such troubles and the motor is now in course of active production and on a large scale.

A few days ago we saw in Detroit in one of the factories there the process of manufacturing the forgings of the Liberty motor cylinders. All of the forgings are being made in one plant, and that plant is to supply the trade with Liberty motor cylinders. The forgings are made by a hot-forging process from seamless tubing, and they were being put through at the rate of 1200 cylinders per day. The factory was planning to double that capacity and they are ready to go still further and increase capacity as the needs require.

Perhaps in conclusion I should mention two or three problems not solved yet and which are of special importance, and which I shall take the liberty of calling to your attention and recommending to your special thought and study.

One is the supercharging airplane engine: the engine which shall be supplied with means to secure the maintenance of the power at high altitudes, and not suffer the loss normally attendant upon working in a rarified atmosphere. If we have the same engine working at sea level and then soaring upward, it is found that the power diminishes with the density of the high-altitude atmosphere. Many devices have been suggested, but the problem is to realize the end in the most effective way and with the least cost in excess weight and added complexity. If we can solve this problem we can assure our supremacy in high-altitude service.

Another development is that of modifying at will or automatically the pitch of the airplane propeller. It is of small use to maintain power if the propeller is to maintain its same pitch in an atmosphere of reduced density. The engine will speed beyond the limit or the rotation speed of the engine will impose a limit upon the power which could be developed.

Some way or means is required, therefore, for properly modifying the pitch of the propeller in order that we may without undue sacrifice of efficiency cause the rotative resistance of the propeller in a rarified atmosphere to correspond in some degree to the continuing torque of the engine.

Another problem is that of the spark plug. The modern spark plug has been a development in response to automobile conditions, in response to the compression pressures which prevail in automobile practice. It is found that under the higher pressures in aeronautic service the spark plug, based on the automobile program, rapidly breaks down. The insulating characteristics are lost in one hour or two hours or ten hours, and there is a bewildering uncertainty as to the life of the spark plug under present conditions. This is one of the outstanding problems, particularly with reference to the increasing demands of modern airplane service.

One final thought is this: Throughout this trip of inspection we were very strongly impressed with the serious purposes with which the captains of industry in this field of production are approaching this problem. They realize its magnitude and its importance, and they are approaching it with high purpose and patriotism; and with the presence of such a pervading spirit in the industries of this country we are going to make good with regard to our program of airplane production. Not quite what was hoped, perhaps, in the first flush of anticipation, but we are going to make good, and the production in airplane manufacture will not he our least contribution toward settling this world war, and toward settling it in the way we all hope it will be settled.

THE SOLUTION OF THE CANTONMENT CONSTRUCTION PROBLEM

By LEONARD METCALF,[1] BOSTON, MASS.

I HAVE been asked to tell you the story of the work of the Cantonment Construction Division, an organization which did not exist six months ago, which has built in this incredibly short period of time sixteen National Army Cantonments, with 26,500 buildings to house and care for 675,000 men; two embarkation camps for 43,000 men; one quartermasters' training camp for 18,000; additions to the regular army barracks, for 100,000; repair shop units; and the semi-permanent structures at sixteen National Guard camps, to care for 462,000 men; and which has designed and purchased equipment for certain large plants for our army in France, a tremendous task involving 200,000 men, and an estimated cost of approximately $187,000,000, over three-fourths of which has already been spent. It is a wonderful story, not of planning and preparation, but of doing seemingly insuperable tasks daily, an inspiring story of loyal and effective coöperation between army officials and civilians, the one with army traditions and experience, the other with their widely different professional and commercial training.

The cantonment work is done, a splendid achievement, creditable alike to the Government, to this bureau of the army, to the construction quartermasters at the camps, to the supervising engineers and contractors, to the railroads and supply men and to all concerned.

Not a sandpapered or polished job, but rough-hewn, strong and calculated to serve. Wasteful in certain details, no

[1] Consulting Engineer.

doubt, but economical in the best sense, for the saving in time here has saved life and treasure on the long firing line across the water.

Where can you duplicate the experience, involving as it does an expediture of $150,000,000, in six months' time, three times the maximum rate of expenditure in twelve months on the Panama Canal, and which increased tenfold the normal building activities of the country, without substantial increase in the cost of materials, from beginning to end of the task, due largely to the work of the War Munitions Board of the Council of National Defense and its committees; involving meager compensation to the administrators, designers and supervisors and voluntary service on the part of many skilled advisers, who dropped important personal obligations to go to Washington for days, weeks or months in response to telegrams asking for help; voluntary coöperation and work by the railroads, telephone, electric and other utilities, and substantial expenditure without guaranty of return; contractors taking contracts to build structures estimated to cost from $3,000,000 to $4,000,000 and actually building these and many additional structures so that the final contract sums ranged from $8,000,000 to $10,000,000 per cantonment, nearly doubling the necessary construction period, but without increase in compensation, and this when the compensation upon the building of the National Army cantonments was limited, *not* to a *profit of 10 per cent*, as has so often been stated, but to a gross return of *$250,000*, averaging for the sixteen cantonments less than 3 per cent. out of which sum had to come an overhead expense of probably $100,000 and interest charges upon $600,000 to $1,000,000 of working capital amounting to perhaps $25,000 to $40,000 more, leaving a *net profit to the Contractor of substantially less than 2 per cent?*

Broadly speaking, labor costs alone have risen, following closely the local cost of union labor for an eight-hour day, with time and a half or, in some cases, double time for overtime, according to the prevailing local conditions: and even as to these, there are the extenuating circumstances of increased cost of living, the fact that the settlement of the labor rate disputes was not always left to this Board for solution, and, most serious of all, the failure of the Government to adequately control priority of its construction, which would have prevented the bidding up of the local labor markets by its own agents in different departments having contiguous construction underway.

I speak advisedly, not loosely, for the conditions of the work may not equitably be overlooked. They are vital. The work had to be done, *was* done, without delay, and no plea or excuse of inability to get labor, throughout the work, at rates prevailing at its inception, would have excused postponement of completion or have brought back life or treasure spent at the front during such delay.

Call Comes for Organization

On May 17, 1917, Brigadier-General I. W. Littell, then Colonel of the U. S. Quartermaster Corps, was detailed by the Secretary of War to assemble and direct an organization to be known as the Cantonment Division of the Quartermaster Corps, to provide facilities for training and housing the new National Army and the National Guard. He called to his aid Major, then Captain, W. H. Oury, Major then Captain, R. C. Marshall – both of the Regular Army, and Major Dempsey of the Officers Reserve Corps, the former of whom had been supervising the enlargement of some of the army barracks, the second of whom was soon engrossed in the new cantonment construction, and the last of whom took up the question of auditing construction expenditures.

Neither funds nor quarters nor personnel were available for the designated service, for the appropriation bill which carried $77,000,000 for the inception of this work was still in debate in Congress.

This was the opportunity of the Committee on Emergency Construction of Buildings and Engineering Structures of the War Munitions Board of the Council of National Defense. Of the latter Board Frank M. Scott, of Cleveland, was the able chairman.

This committee was made up of five experienced builders: William A. Starrett of New York City, architect and formerly of the building firm of Thompson-Starrett Company, Chairman; C. W. Lundoff, of Cleveland, Ohio, President of the Crowell, Lundoff, Little Company, building contractors; M. C. Tuttle, of Boston, General Manager of the Aberthaw Construction Company; Capt. Wm. Kelly of the U. S. Engineer Corps, who, however, was unable to give much time to the work of the Committee, owing to other army obligations; and Frederick Law Olmsted, of Boston, engineer and landscape architect. To their assistance they called many engineers, city planners, architects and specialists of different kinds, to act on sub-committees or to give desired advice on special subjects.

Circumstances thus made it possible for the Committee to render General Littell service in an advisory capacity on the formation and civilian personnel of his organization, on the form of contract under which the work should be built, on engineers, city planners and contractors of responsibility to design and build the cantonments, and at the moment to make the most of the time which might elapse before the appropriation bill should be passed by Congress, by preparing typical plans or layouts for the buildings and other structures involved, making topographic plans of the sites, studying the water supply, sewerage and other public-service facilities, the best arrangement or grouping of structures, adapting the typical plans to the local topography—all through the voluntary service of achitects, engineers and city planners.

Organization Adopted by General Littell

The organization proposed by the Committee and adopted by General Littell comprised four different groups, reporting to his staff officers:

- Major Frank M. Gunby, member of this Society and formerly associated with Mr. Charles T. Main of Boston, in *Charge of Design;* assisted by Major F. B. Wheaton, Captain Doten, Dabney H. Maury, Clarence Goldsmith and W. M. Johnson of the National Board of Fire Underwriters, and George Gibbs, Jr., of Boston.
- Major Robert E. Hamilton, formerly Purchasing Agent of Stone & Webster, in *Charge of Materials and Transportation.*
- Major M. J. Whitson of Seattle, formerly partner of Grant, Smith & Company, in *Charge of Construction;* assisted by a staff of division engineers, Peter Junkersfeld, Charles L. Parmlee, Ezra B. Whitman and others.
- Major Dempsey in *Charge of Accounting.*

Since that time, benefiting by the earlier experience and with a view to handling the additional work of building ports of embarkation, ordnance depots, coast-artillery posts, medical department construction, mobile ordnance school barracks, quartermasters' warehouses and miscellaneous plants, the or-

ganization has been enlarged, modified and strengthened, Major Marshall remaining in command under General Littell, assisted by Captains Thompson and Maupin; the engineering branch being still in charge of Major Gunby; the construction of Majors Whitson and Junkersfeld; the materials of Major Willcutt; finance and accounting of Major Dempsey; construction and repair of Major Zollars; the law, Major Shelby; information, Captain Erck; transportation requisitions, Captain Ritche and Chief Clerk Moreland; and several other engineers of large reputation and breadth of experience, such as Lincoln Bush, Major Betts, Warren R. Roberts, and others, have been drawn into the service, fine examples of personal sacrifice.

The Committee on Emergency Construction of Buildings and Engineering Structures first undertook to get local investigations under way and the preparation of typical building plans. As soon as cantonment or camp sites were designated by the department commanders, approved by the army staff and reported to General Littell, city planners and consulting engineers were asked to go to them, voluntarily and at their own expense, to make topographic maps, study the water-supply and sewage-disposal problems, the location of railroads, roads and other utilities, and to report to Washington with all despatch. Within a week's time, in a number of cases, topographic maps were prepared of areas of from 1000 to 2000 acres, and essential information was obtained upon the points desired. Meanwhile, leading architects and engineers of this section of the country had been summoned to Washington to assist in the revision of the plans for the barracks, the preparation of typical plans, which were afterwards adapted to the local topography, on the ground, by the staffs sent to the individual camps.

Form of Contract Prepared

Contractors, too, were assembling in Washington to see if they could be of service and the Committee directed its efforts to the preparation of a form of contract under which a work, of the magnitude then contemplated and since largely increased, could be built with reasonable certainty within a time limit of ninety days, in the face of congested transportation conditions, soaring materials and labor shortage.

A form of contract inducing speed was essential. This compelled the elimination of the financial hazard to the contractor, and for the protection of the Government the selection of contractors solely on the basis of experience, merit and integrity. It was at once apparent that the competitive form of contract dictated by past Government precedent was out of the question with the time limit available and the conditions to be faced.

Lump-sum-profit basis form of contract was weighed and rejected as likely to emphasize the idea of barter and trade rather than of fitness and competency, and to embarrass the Government in awarding contracts to more experienced contractors if lower profit basis were offered to the Government by less experienced or less desirable men.

The cost-plus-percentage basis, however, appeared to meet the fundamental requisites and the addition of a limiting lump-sum profit made the Government safe in its operation in the event of substantial increase in the amount of work done under it. The combined efforts of many able men—lawyers, engineers and contractors, as well as of various engineering organizations, produced the "Emergency Construction Contract"—a radical departure from Government precedent—which provided essentially for the construction of the work on the basis of cost plus profit, the latter varying from 10 to 6 per cent with the magnitude of the work, with the important limitation of an upset profit of $250,000, from which sum, however, the contractor had to meet his own office overhead and interest costs. It is interesting and but fair, in the face of some of the unfounded public criticism which has been heard, to note the effect of this upset limit of profit. On the construction of the sixteen army cantonments, involving a total cost of approximately $134,000,000, or upward of $8,000,000 per cantonment, the nominal profit to the contractors will be less than 3 per cent, and after deducting the probable contractor's overhead and interest costs, the *actual profit* substantially less than 2 per cent—in some cases perhaps less than 1½ per cent. Upon the construction of the National Guard camps, involving a total cost of $36,000,000, or about $2,250,000 per cantonment, the contractor's fee is higher, approximately 7 per cent, but as the overhead cost is also proportionately much higher the total return in cash for the six months' period of work is substantially less than in the cantonment construction.

Inasmuch as nearly all of the war construction work now being executed by the Government is being done on an emergency basis, where speed and not cost must control, thinking men will be careful not to criticize carelessly and will weigh fairly the influence of the time element. In the execution of work on such a tremendous scale, under prevailing labor and material cost conditions, it is inevitable that money will be wasted and mistakes made, but the work must be done—expeditiously done—that the saving may be one of lives and days, not dollars.

While the preliminary investigations were under way, the Committee sent out questionnaires concerning contracting firms in this country, seeking references, a statement of the magnitude and kind of work executed during the past two years, the number of men handled and fed at one time, and the financial resources of the concern; obtained the rating of the contractors by important financial-credit concerns, and called to its assistance John H. McGibbons, formerly of the U. S. Fidelity & Guaranty Company of Chicago, to aid it with his broad knowledge of the standing and financial credit of contractors.

Committee Selects Contractors

Armed with this information a sub-committee of five men, with Mr. Starrett as chairman, selected the contractors deemed best qualified at the moment to undertake the work and who had demonstrated in their past experience their ability to handle work of such a character and upon such a scale; and reported its findings to Mr. Scott's committee of the War Munitions Board. From the latter committee, recommendation passed to General Littell, and after submission of the evidence and recommendations to the Secretary of War, appointment was finally made by General Littell. The subseqent experience in the building of the camps seems clearly to have justified the course of procedure, and it is greatly to the credit of the Government that it can be said, unequivocally and with absolute candor, that these appointments were made on the merits of the case, as they were understood, without political pressure or "influence." It is further greatly to the credit of the leading firms of contractors that as a rule their representatives left Washington before they knew whether they were to be recommended for specific work and before appointments were made, though personal disinterestedness and unwilling-

ness to use political influence cannot be claimed for many others who sought contracts.

The Committee then turned its attention to the preparation of forms of contract for the employment during construction of the engineers and other experts necessary at the camp sites, being greatly assisted in its work by different members of the national engineering societies, who voluntarily came to Washington in response to telegraphic request, to assist the Committee.

Engineers believed to be most competent and at the moment available for service at the various cantonments were also designated, appointments in all cases being made, of course, by General Littell and his staff.

In this way the Government had the voluntary service of many men skilled in the particular field involved—in building up an effective organization and personnel for the work in hand; men who coöperated in a thoroughly disinterested way with the administrative army board in responsible control. The results attained here seem to indicate the advantage of such a purely advisory board, the recommendations of which could be followed, modified or rejected with cause by the duly constituted executive authorities.

Details of Camp Construction

Time forbids the attempt to chronicle the details of camp construction executed under the direction of General Littell and his staff. The sixteen National Army cantonment sites were approved at various dates ranging from May 31 to June 27, 1917, contracts for their construction were executed between June 15 and June 23, and work was begun between June 13 and July 6. On September 4, or in less than three months' time, about 450,000 men could have been taken care of at the cantonments, on the first-adopted basis of 200 men to the barrack, later reduced to 150 men; and today, December 5, 1917, the camps are substantially all completed, despite the great increase in construction involved by the prescribed increase in cubical air space per man in the barracks (from 365 to 500 cu. ft.), the addition of remount stations, to care for 10,000 horses at each of the camps having them, hospitals and other changes, which have nearly doubled the work originally contemplated.

The story of the construction of the National Guard camp equipment is similar, except that the work involved is only about one-fourth of that involved in the construction of the cantonments.

A few figures in regard to the magnitude of the work, involved in building the sixteen National Army cantonments, may be suggestive. There were required upwards of 800 million feet, or 37,000 cars, of lumber, and 40,000 cars of other material, a total of 77,000 cars upon the cantonment construction, without allowance for the materials ordered locally and not from Washington—the total involved in the cantonment, camp, and embarkation-station construction to October 31 being approximately 112,000 cars—756,000 squares of sheathing paper, 800,000 of roofing paper, 172,000 doors, 34 million square feet of wall board, 106,000 kegs of nails, 314,000 barrels of cement, 282 miles of wood and cast-iron pipe, 3550 hydrants, 75 miles of fire hose. The total area of land rented or controlled at the cantonments is 261 square miles.

As the construction of the cantonments was drawing to an end the work of this bureau was extended to cover the construction activities of the army, except in a few special cases, such as in the aviation corps, where it was thought wiser by the Secretary of War to leave the construction in the hands of the departments for the use of which the structures were to be built. This new work is well under way, constantly growing and broadening.

Whole Work Monument of Loyalty and Ability

As one reviews the work accomplished by this cantonment division, he cannot but be thrilled by this fresh evidence of the resources of these United States and the loyalty and ability of its people, remembering how recently and in what manner this bureau was organized; that cantonment construction involved but one branch of governmental activity and one comparatively small group of men; and that similarly inspiring evidences of effective service are to be found in all of its other branches.

If constructive criticism is warranted at such a time, it may be said that one of the greatest needs today, as it was recognized to be six months and more ago, is better coördination of the governmental construction program, ways, means and priority. The subject has been studied in its various phases by many men, but no sufficient authority has yet been delegated to accomplish substantial progress. Effective organizations of thousands of men have been built up with large expenditure of time and money, only to be disbanded on the accomplishment of their specific tasks, when these organizations might have been transferred directly to new tasks, with telling effect, had there but been the necessary government authority to plan well-coördinated effort in its construction field.

In an emergency of the magnitude created by this war, and in the face of the Government's failure to prepare for it, the question immediately arose as to the basic principle which should govern the selection of the agencies to accomplish the enormous task before the Government. Should the governing bodies be creative or essentially administrative? For instance, should the necessary design of warehouses, hospitals, power plants, terminals, nitrogen- and gas-producing works, engine and aeroplane construction, and other work, be executed by old governmental bureaus with greatly enlarged personnel, by new governmental bureaus to be created solely for this purpose, or should it be entrusted, under proper governmental supervision, direction or control, to well-established, adequate and efficient engineering organizations, skilled along these lines and competent to handle the work, of which organizations there were many in the country? Similarly, should the different army corps, with totally inadequate personnel, act as purchasing agencies, or should this highly specialized work be delegated, under governmental supervision, to existing firms of high capacity and reputation?

Mr. Balfour, in his visit to this country, had wisely cautioned against the mistake made and the loss of time incurred by England in building up new bureaus to do the work before the Government, instead of utilizing well-established and live organizations enlarged and controlled by the Government, if necessary, to the end not only of saving time and expense, but also that when the war was over the gigantic work of reconstruction and readjustment might be facilitated by the enlargement and strengthening of these existing private or corporate agencies, instead of being retarded and hampered by their disruption.

The Committee on Emergency Construction had this thought clearly in mind and predicated its efforts on the three hypotheses:

1 The work must at all times be under the superior control of the United States Government, through its duly accredited representatives

2 Services must be equitably compensated
3 Government methods of contracting for and compensating construction work and services should be such as to utilize and strengthen and not to impair or destroy existing organizations.

Unfortunately, the Government has not carried this principle as far as it might advantageously have done, but has in a number of cases built up in Washington and elsewhere new agencies for executing work instead of employing existing ones competent to render effectively the service desired, thus failing to benefit by the mistakes of England and France and the helpful advice of Mr. Balfour. But, on the whole, and in spite of the waste thus involved, surprisingly rapid and very commendable progress has been made.

BUSINESS MEETING

Address by President Hollis on Society's Activities—Presentation to Society of Bust of Rear Admiral B. F. Isherwood—Award of Prizes for Papers—Appeal for Mechanics for Ordnance Department

The annual business meeting of The American Society of Mechanical Engineers convened in the Auditorium of the Engineering Societies Building on the morning of Thursday, December 6, at 10 a.m. The meeting was called to order by President Ira N. Hollis, who delivered a forceful address upon the activities of the Society for the year 1917. In this address the President laid before his hearers a clear conception of the internal and public activities of the Society. He presented a detailed statement of the work of its Council, committees, sections and branches for the year. He described the nature and magnitude of the Society's service to the public in the war, and defined the extent to which he thought the Society could continue to render such service. The text of the President's address is appended to this account.

The Secretary said he was sure that every member would be glad to express his appreciation of the tremendous devotion of the President to the work of the Society in the past year and of the energy which he had displayed in discharging the many functions and duties of his office. He then presented formally the reports of the Standing Committees for the year, which were published in the December issue of The Journal, discussing each one in turn in detail. He pointed out that the income of the Society had risen in the last few years from $50,000 to $230,000 a year, during all of which time the activities had been continuously extended. The Society was in a unique financial condition—it had not a single dollar of indebtedness of any kind outstanding, and moreover had $50,000 invested in bonds, $21,000 in banks and $10,000 of the First Liberty Loan and $10,000 of the Second Liberty Loan—all put away against emergency. These splendid results were due to the consistent, business-like attention to our activities on the part of Mr. R. M. Dixon, Chairman of the Finance Committee, and Mr. I. E. Moultrop, Chairman of the Increase of Membership Committee. The Meetings Committee, under the chairmanship of Prof. R. H. Fernald, had devoted itself assiduously to its work, as attested by its wonderful progrom for the Annual Meeting. The Publication Committee was striving to make the publications inclusive of all engineering and the most pertinent to mechanical engineering.

Five amendments to the Constitution were next presented by Prof. F. R. Hutton, Chairman of the Committee on Constitution and By-Laws. These amendments were first presented at the Spring Meeting in Cincinnati in May 1917, and were published in the October issue of The Journal. Each amendment was, by vote of the meeting, ordered put to letter ballot.

The first amendment was to bring the Constitution into accord with the New York State Law and to make the quorum in the Council a majority. The second amendment was to provide that administrative committees be officially represented in the Council, the Standing Committees on Administration to be Finance, Meetings, Publications, Membership, Local Sections, Constitution and By-Laws. The third amendment provided for the appointment of such annual committees as might be required from time to time. The fourth amendment was for the purpose of enabling the Society to meet its greater responsibilities in public matters, while still excluding discussions of partisan politics. The fifth amendment was to remove the present bar to the approval or adoption by the Society of any standards presented through its committees or otherwise; heretofore standards have always been received, but not approved or adopted.

The next business was the award of the Student Prize for 1917 to H. R. Hammond and C. W. Holmberg for their paper on A Study of Surface Resistance with Glass as the Transmission Medium. A report of the committee on this award was made by Professor Hutton, who also presented the prize. Professor Hutton said that there was a pathetic note to be added to the report—the Society had just received information of the death of Mr. Hammond. Mr. Holmberg was present and received his prize in person.

At 11.00 a.m., while Professor Hutton had the floor and was presenting the amendments to the Constitution, the President interrupted the proceedings to introduce Lieut. B. C. Detchon, who made an eloquent appeal on behalf of the Military Engineering Committee of New York for help for the Ordnance Department—the mechanical-engineering department of the Army—which he said was in urgent need of mechanics for repair work in France. He suggested that each member present deprive himself of some of his men for the time being to supply this immediate need.

Lieutenant Detchon also appealed for aid, personal and financial, for the Military Engineering Committee, whose activities in connection with the war were manifold.

Prof. A. L. Williston called attention to the number of trained men who will be needed in this crisis, and pointed out the opportunity which colleges and technical schools have of serving their country through putting at the disposal of the Government not only their technical equipment, which is immensely valuable in this emergency, but their teaching experience, which is indispensable.

He made a motion that the Council immediately appoint a committee to investigate whether coöperation between the War Department and the technical schools cannot be started immediately to put into effect training schemes for technical men for the War and Navy Departments, which was carried. The

motion [illegible] by [illegible] E. [illegible], Prof. L. P. Breckenridge, the President and the Secretary.

Following Lieutenant [illegible]'s appeal, an impressive ceremony was held of the presentation to the Society of a bust of the late Rear Admiral Benjamin F. Isherwood, Honorary Member. The presentation was made by Mr. William M. McFarland, Past Vice-President, and the bust was unveiled by Benjamin F. Isherwood, grandson and namesake of the Admiral. President Hollis accepted the bust on behalf of the Society, taking the opportunity of paying his own personal tribute to the genius of this great engineer. Mr. McFarland's and President Hollis's remarks will be found on a following page.

The business meeting was followed by a Local Sections Session, an account of which is given in the Society Affairs section of this issue of THE JOURNAL.

ACTIVITIES OF THE SOCIETY FOR 1917

BY IRA N. HOLLIS, PRESIDENT

THE past year has been of such vital influence on the future of our profession, as well as of our country, that I desire to lay before the members a brief report of our activities and our possibilities for the future. This is not intended to replace the annual report of the Council, which is a detailed statement of all business during the entire year. The only regret I have is that the completed Council report has been delayed to permit me to make such extracts as seemed necessary toward a consistent comment upon it. The reports of Committees are, of course, in print for this session. It seems wise, on the whole, to bring the Society up to date in a general way.

The American Society of Mechanical Engineers was organized in 1880 for the purpose of promoting engineering science in every way. At that time mechanical engineering was hardly recognized as a profession. It was never distinctly a part of civil engineering, but grew out of the modern demand for men to take their places in industries and manufacturing. The few who practised mechanical engineering in the early days were essentially designers of machinery or investigators, like Leavitt and Thurston. Consequently, for many years the papers of the Society were confined to technical and educational subjects for the benefit of its members, and through them for the benefit of the public. Our Society is fundamentally educational, and that must always be its chief function if it is to continue as a society for the advancement of applied science. Through the influence of the engineering colleges and the rapid advance in manufacturing, the profession has changed, and the mechanical engineer is no longer tied exclusively to technical questions. The old guard has given place to consulting engineers who deal with industrial and power questions on a large scale, and with the management of great industries, leaving the details of design and construction to thousands of young engineers who have been absorbed by manufacturing and operating companies. We must recognize also that mechanical engineers have by training and experience become leaders in business, especially in business connected with manufacturing.

SOCIETY HAS RESPONDED TO CHANGES IN CONDITIONS

To this rapid change during the past generation, the Society, while holding to its original purpose of advancing engineering through the discussion of scientific papers, has responded in proportion to the demands of the members, to the vision of its officers, and to the needs of the country, exactly as the constitution of the United States and the governments of our commonwealths have been made to fit a growing population and a larger understanding of coöperation. While there have been differences of opinion on all kinds of subjects (and no society is in a healthy state unless there are differences of opinion), and while we may have missed some opportunities for usefulness, on the whole our Society has not failed of its duty to the country. We have never been leaders of propaganda on political and social reforms, and we cannot be without running the risk of losing our character as a scientific organization or splitting up into cliques that would destroy one another. On the other hand, our annual meetings have provided a forum for discussing and assisting great advances in industrial organization and in the art of manufacturing. It is here, for instance, that papers have been presented on a wide range of subjects, extending from test codes for power and the boiler code for the construction of safe boilers, to standardization, testing of materials and scientific management.

The attitude of the Society, as a whole, is well indicated by the character of the men who have been elected to the governing boards. They have invariably been friendly to the coöperation of the engineers with the public in the proper development of our material resources, and have been both sympathetic and responsive to the desires of the members. In going about the country during the past year, which I have done systematically as part of my duty while president of this Society, I have never heard a word of complaint against the Council or their methods, excepting in a very few cases, unhappily, open to suspicion of an unbalanced judgment. Our Society does not stand for that.

We must remember that in a national society covering the vast range of territory we have in America, there are many scattered groups that seldom come in touch with one another. The general headquarters must necessarily be in some one locality, and New York was long ago chosen as perhaps nearer the center of the enterprise of the world than any other city. The Atlantic Ocean is nothing now, and New York places us in almost the center of gravity of manufacture. Nevertheless, a group of our engineers in San Francisco, for instance, is far removed, and they seem sometimes as if they were not genuinely a part of the national society; but it is a mistake to feel any isolation. Every member of our Society ought to know that he is very likely to get out of the Society what he puts into it, and any effort toward inproving the Society or toward educating its members through scientific papers or by contribution on broad, general questions is quickly recognized.

During recent years the Sections of the Society have been regularly organized, and the Sections Committee has been established to encourage activities within every Section. There is a session at this annual meeting that will bring their representatives together for a concerted study of how to make the Society reach out even more effectively to every one of its members.

DEMOCRACY OF THE SOCIETY

The democracy of the Society cannot successfully be assailed. It has been suggested that the president has it within his power to continue his own influence by appointing his own kind of a nominating committee for the officers to succeed him. To use the language of the street, this is absolute

rot. It has not been the custom for the president or the officers to influence the choice of the new Council members, and almost invariably the whole Society has been solicited for suggestions. The consistent tendency is toward a greater participation of the members, and therefore toward greater democracy as we learn how to be wisely democratic. This Society is not an assemblage of the "bandar log," ready to chatter over the latest fad, but a union of men sincerely interested in benefiting their country through science. That we must always remember in scanning proposed reforms.

Furthermore, the Society is in the hands of its members and not in the hands of a few corporations. We must not permit ourselves to go to an extreme because corporations have sinned in the past, and because they are going to sin in the future. The directors of all corporations are human as our directors are human, and they will make mistakes over and over again, and we will help to correct them over and over again, but our Society is not a creature of any public-service corporation, and it never has been. It stands for truth in science, and it ought to help the truth in the social life of the country. Its purpose, however, is the truth in science and not a partisan conception of the truth.

One has only to take a list of the officers who have served our Society to find that all aspects of modern industrial life have been wisely represented. There is no earthly reason why our Council should be organized as the enemy of the men who conduct our great affairs, nor should it be organized as their special advocate. It is organized for the truth and nothing but the truth. Consequently, we should not as a Society permit ourselves to be led away by catchwords, nor should we permit ourselves to be fooled by a list of our mistakes. We know that no human institution ever can be freed from imperfection and mistakes will always be made. and in our country, thank God, will always be corrected.

The Society's Public Relations

It is sometimes difficult to determine how far the Society ought to go in its public relations. At this time, while we are at war, there is no limit to the sacrifice that ought to be made to the common good, and to the work that ought to be done by the members individually and the Society as a whole toward the success of our country in war. There is a difference, however, between individual activity and collective activity. This is the time when the individual can offer himself, and when the Society can best serve as simply the intermediary for assisting the individual to serve well. That we have systematically tried to do. At the present date, fully ten per cent of our membership is in service. In ordinary times of peace it is sometimes a question how far we ought to depart from the orderly discussion of technical and scientific papers. We have the right by our charter at any time to enter into legislative questions or into any of the great economic questions before the country. We have no right to take part in partisan politics, either from the point of view of the legality of our charter or from the point of view of policy with regard to the future development of our Society.

We have taken part in many things of public interest and in many things involving the public. For instance, in our Boiler Code we have affected legislation in many of the states and municipalities. In our Committee on Standardization we have done a great deal of good work, culminating finally in a general Standardization Committee to represent many societies so that we may work together. In our Test Code for Power we have had a very wide influence throughout this country on the development and design of power stations. It is not necessary here to go into the details of our activity, but I think it is easy to make evident the fact that our Society has always been one of public relations.

In connection with public relations there are sometimes great differences of view on the part of engineers generally. I have been disposed to ask the question, "Is it right that any one society of engineers should take a stand on any public question that affects all engineers without a full discussion of the subject with other engineering societies?" The engineers have only slowly come to a proper representation of themselves before the public. If we are to have our legitimate influence over public affairs we all must act together. It is only common sense then at least to thrash out subjects before a senate of the engineering societies, or what we have called an Engineering Council. To that end the American Society of Civil Engineers, the American Institute of Mining Engineers, The American Society of Mechanical Engineers and the American Institute of Electrical Engineers have joined together to form the Council for considering all matters referred to them by a single society or by our Government. It is the only method of taking up public affairs. Consequently, we may well ask ourselves the question at the present time, "How far ought any single society to act alone?"

Our Activities for the Year

I am glad to call attention to some of the details of our activities during the year. The election of Major-General George W. Goethals as an honorary member adds one more to the long list of distinguished men who have had membership in our Society. This kind of membership has never been refused, and it is rightly regarded by us as the highest acknowledgment we can make to great service in engineering. The regular membership of the Society has been steadily increasing, mainly due to the efforts of the Increase of Membership Committee and to the good standing of the Society as a useful aid to engineers who are going into mechanical engineering.

The Local Sections all over the country form a very important adjunct in this regard, and the administration has been wise in permitting them to invite non-members of the Society to all meetings. The coöperation of these Local Sections is encouraged in every way, in order that they may have touch with the sections and branches of other societies. Every engineer in the United States ought to have membership in a national society, and also some relation to the local sections or local societies. It is the only method by which we can be drawn together as engineers.

Attention is called in the Council report to the number of Local Sections in the country. There are twenty-two, one of which is a state Section, with five branches. This is a very interesting departure from former practice, and promises rich developments in the future. Every state could have its organization of engineers, with branches in the principal cities. Our Society would accomplish much good by fostering that idea.

It is not necessary for me to refer here to the Cincinnati meeting beyond the remark that it will go down in the history of our Society as one of the great meetings where Cincinnati outdid herself in the entertainment of her visitors. We met with the Machine Tool Builders' Association, and the meetings are rightly emphasized in the report submitted by the Council.

The Student Branches hold out possibilities for excellent coöperation between the colleges and our Society. This has not been developed as fully as possible, and we should, by

visits to the colleges, by cooperation with the Society for the Promotion of Engineering Education, and by a better acquaintance with the faculties, lend all possible aid toward the better education of men who are going to come into the profession of engineering. We ought to have some systematic part in education.

Our Big Work of Classifying Engineers

There has never been a more important year to our Society than the past, during which war has been declared against a strong combination of nations and the country has been called upon to form and equip a large army. We have all been eager to serve in some way. At the same time, the place for service has not always been self-evident. In the inevitable confusion, no system was adopted by the War Department or by the Navy Department in the organization of men for commissions in either service. Orders were issued and recalled for a great variety of things, so that even at this time an engineer is puzzled where to apply. Our Society has done something to help in this situation, but not all that might have been accomplished under more favorable conditions. We have joined with other societies in the Engineering Council to form a committee for tabulating the members of our Society as to their attainments, their previous experience and their willingness to serve. This committee, with George J. Foran as chairman, has done yeoman work in devising an admirable system for obtaining the information required. Inasmuch as the tabulation is a long-time piece of business, they have quickly listed several thousand names from the various societies as specialists along various lines. The names have been submitted to the departments of the Government and to the industries generally as they have been requested.

It has been very puzzling to know just how far the Society could go, as the responsibility for the selection of men and for the suggestion of the needs of the service must rest with the commissioned officers of the army and navy, under orders of the President. Wherever the Society has been requested to lend its aid in the procurement of men for commissions for special service in civilian lines, or for the formation of regiments, it has gladly responded, always supplying more names than were needed in order to be absolutely fair with all members. The members of the office force, from the secretary down, have had a full realizing sense of the obligations on the part of all of us to serve in every way and to help in the formation of an army so that our country might be most speedily prepared.

The tabulation of engineers, if carried through all the societies, national and local, will be a directory of American engineers. It should be catalogued and cross-catalogued for names and branches of the profession. There should be at least two copies, one filed in New York and one filed with the local society in which a member is resident. Such a directory can be made useful in the readjustments of our industries in peace after this war is over and in the better organization for the conduct of business. The United States never has been able to coöperate well in industries. In fact, such coöperation has been discouraged under the idea that it might in some way defeat competition, which is said to be the life of trade. Nevertheless, coöperation ultimately means exchange of information, and a resulting reduction in the cost of everything that we make.

There is another aspect of this, so far as the individual societies are concerned. Every society, and ultimately the Engineering Council, ought to provide some method to assist the younger members. An employment office is a perfectly legitimate part of our activity, and, as a matter of fact, it has been carried on by The American Society of Mechanical Engineers for many years, to the great satisfaction of many men who have found positions through the office here in New York.

The Society and Standardization

Reference is often made to standardization, in which our Society has taken a very active part for years past. The committee appointed to act with other committees will assist in placing the development of commercial standards among the men best able to pass upon them. The example of the Society of Automotive Engineers should stand as an inspiration to us toward the establishment of all kinds of commercial standards to facilitate manufacture; although it was much easier for that society to promote standardization in the automotive manufacture, because it was one of the methods by which they could get their orders filled. Where the steel industries were called upon to provide hundreds of different kinds of steel, many of them for the same purpose, and hundreds of different dimensions, where comparatively few would have sufficed, it was imperative that the manufacturers should get together, and they have done this effectively. Our Society stands at a disadvantage with respect to standards, as it has nothing of the commercial about it, and no method of forcing upon any manufacturer its findings with regard to standards. We depend, then, upon the slow process of persuasion.

One of the aspects of standardization appears in the controversy over the metric system. There is much difference of opinion about the wisdom of replacing the English units with the French units. Many sincere men believe that we ought not to make any change. Others believe as strongly that we ought. It would be wiser, on the whole, for the Society to maintain this place as a forum and to keep out of this controversy as a society until the way seems more clear. That will not prevent any member of the Society or any group of members writing on the subject, under the encouragement and for the benefit of our membership and for the benefit of the country.

One of the industries that has grown with remarkable rapidity in the past few years is that pertaining to gages of all kinds for the manufacturing of munitions and other supplies. Gages are as necessary in time of peace as they are in time of war, but not in such great quantities. The mistake made by the Government has been the neglect to accumulate a large stock of gages. Last spring in Cincinnati very strong representations were made to the departments in favor of a central locality for the comparison of gages and for certifications as to their correctness. Congress appropriated a large sum and authorized the Bureau of Standards to take on, as part of its function, the comparison and certification of commercial gages of all kinds. This is a radical departure, and it should lead to a great improvement of manufacture in many respects. Our Society has appointed a committee to serve as consulting engineers for the Bureau of Standards in connection with this new departure. We as a society are prepared to assist the Bureau, which is doing such fine work for the country.

Another question which has come up during the year grows out of a request on the part of the Bureau of Mines and the fuel administration to assist in fuel conservation. The whole subject was referred to the Engineering Council, and through the Council consulting engineers have been appointed for the Bureau of Mines to advise in regard to the technical matters connected with fuel conservation and with the use of fuel. A

committee was also appointed at the invitation of the United States Chamber of Commerce to serve with a general committee on the whole general question of fuel. During the year, committees of our Society were also appointed to assist the Bureau of Mines in various ways, but inasmuch as the war has seriously interrupted the development of the new laboratory in Pittsburgh, these committees have been inactive. Their time will come, however, and they will be able to do for our Government the work that this Society is glad to give.

Our Varied but Vital Activities

It is not necessary to refer at any length to the service of the members of our Society in the army and navy. At this time, John H. Barr, W. B. Gregory and Max Toltz of the Council hold commissions as majors in the army, and are serving in important positions. The Society itself has sent so many to the colors that we would find it difficult to tabulate them here. In fact, it is doubtful if we shall have a complete list until after this war is over. Those serving for the Naval Consulting Board and in other capacities are helping splendidly, even though they are occupying positions less spectacular than those on the lines.

The year has seen an innovation in connection with the meetings of the Council. We held in November a meeting in Chicago, in order to test the value of meetings outside of New York. It seems only right that the larger Local Sections at least should have an opportunity to meet all the members of our Council; not only for their own satisfaction, but also to inform them about the needs of the localities. It is hoped that this plan of meeting in the different large cities from time to time may be carried out in the future. The meeting in Chicago was a great success, as it brought together a very large number of the mechanical engineers. The visiting of the various Local Sections by the Committee on Sections is also an important move in making our members better acquainted with one another and it is quite certain that the journey made by the Committee this fall was useful.

One of the valuable elements of the work in the Engineering Building relates to the Library, in which all the societies share. There is no respect in which we can make our distant members feel more interested and benefited than in giving them access to the library by correspondence. Any member ought to feel free to write for a synopsis of any article or for a search, at a minimum cost, and the library should have duplicates, in order that books might be loaned. They could be sent by express to different parts of the country for use, to be returned within a specified time. This is the practice in many other libraries and it could be made very useful here.

The Power Test Committee, under Mr. Barrus, has long been giving its attention to the details of all kinds of power tests. The usefulness of their work in the past has been amply proven, and every effort should be made to assist them in perfecting the code. A hearing and a discussion in our building has been encouraged. Its results should be bountifully fruitful. It must be remembered, however, that no one group of men will know all power tests. Consequently, it seems advisable to invite sub-committees to work out the different kinds of tests. This has been planned and it is hoped that by advisory boards and sub-committees we may improve our test code.

This Society and the whole engineering world owes a debt of gratitude to the members of the Boiler Code Committee, whose patient work has benefited us so much. The Code is operative in many cities and eventually it will probably apply throughout the whole of the United States, thus promoting the safety and welfare of many men.

I call attention to the printed report of the Council, which will be issued later, for a fuller statement in tabulated form of all that we have done. The development of The Journal as a means of placing important papers most quickly into the hands of readers is extremely gratifying, and under the direction of the Publication Committee and Mr. French's excellent management it has disclosed many unexpected possibilities. The question may well be asked why we continue to publish the Transactions as a separate octavo volume when the whole of our activities may be printed in The Journal. No foreign society ever publishes duplicate transactions. If some way could be found of making The Journal a mouthpiece for all of the societies, the bulky volume issued annually for each society would have a natural place; otherwise, the extra twenty thousand dollars spent by our Society might be saved to make The Journal better.

I cannot close this brief report without a cordial acknowledgment of the politeness and consideration that I have received from Sections and members of the Society. It has been a pleasure instead of a task to serve them as president. The patience and kindness of the office force could not have been surpassed and the untiring zeal of our Secretary, Mr. Rice, for the good of the Society and of our country deserves the warmest acknowledgment from members and their officers.

Presentation of Bust of Admiral Isherwood

Address by W. M. McFarland

The honor and pleasure of making the address in presenting the bust of Admiral Benjamin Franklin Isherwood to the Society was assigned to his old friend and assistant, Commodore George W. Magee, U. S. Navy. Unfortunately, the Commodore has fallen ill, so that this honor has been delegated to me. I am sure that you will all regret as sincerely as I do that we are not to have the pleasure of hearing from his own lips the tribute of this venerable man to his former chief, whom he loved and esteemed so highly.

Fortunately, we have a copy of Commodore Magee's proposed address, which I shall read you in a few minutes; but as the opportunity is afforded me, I wish to pay my own small tribute to the great man whose memory we are honoring today.

It will always be a source of satisfaction to me that I met him a number of times, and once had the pleasure, while I was a youngster in the Navy, of doing a little work for him. My admiration for his genius and ability came from acquaintance with the work he had done, as shown in the published records; but more particularly from an intimate acquaintance obtained from older officers who knew him and all his deeds well.

Supplementing Commodore Magee's address, and remembering that our esteemed President, Doctor Hollis, was also a naval officer, and an admirer of Isherwood, I would emphasize the importance of his scientific work as a pioneer.

In these days of technical societies, great technical journals and splendid textbooks, when the general principles of the science of engineering are so thoroughly established, it is difficult for us to remember that there was a time when many of these principles were either unknown or were considered to be debatable. It is the special glory of Isherwood that he helped to establish a number of the most important of these basic principles.

As showing the state of the art in his early days as an engineer, it may surprise you to learn that a rather careful search through engineering literature showed that the first reproduction of actual indicator cards from a marine engine published in any book was given in Isherwood's work, entitled Engineering Precedents, published about 1856.

Just another word about the enduring value of his work. His reports of experiments are models of what such reports should be. They include a complete description of the apparatus; and the log of the experiment, in each case, gives all the data which could be observed, whether they were immediately applicable to the purpose of the experiment or not. The result of this is that these reports constitute a mine of valuable information; and other engineers, many years after, seeking information on an entirely different line from that for which the experiment was conducted, find in the complete and careful record just the information they want, and which often can be found nowhere else.

Isherwood's wonderful work and personality had so impressed itself upon the older men of the Engineer Corps who knew him well, that to all of us younger men he became one of the heroes of engineering. We worshiped him at a distance. Our dear old friend, Commodore Magee, was his intimate personal friend for more than half a century; and I now have the pleasure of reading his tribute, which I so greatly regret that he could not make in person.

Tribute by Commander Magee

THE pleasant duty has been confided to me of saying a few words in the presentation to the Society of a portrait bust of Admiral Benjamin Franklin Isherwood, U. S. Navy, who was for many years, until his death, one of your honorary members.

This duty is all the more pleasant from the fact that during my active service in the Navy I was associated with Admiral Isherwood during several tours of duty, and especially during that trying time of the Civil War, when he was Engineer-in-Chief of the Navy. I was a young man then, as indeed was Isherwood himself, and I worked for him with all the enthusiasm which a young man feels when he is in constant touch with a great genius and administrator. He honored me with his friendship, which lasted unbroken until his death.

The work by which Isherwood is best known among engineers throughout the world is his splendid series of experimental investigations. The most famous of these perhaps were the ones on the *U. S. S. Michigan* in 1859, to investigate the expansive working of steam. His screw-propeller experiments at Mare Island, in 1868, have, however, been praised just as highly by those who found them a perfect mine of valuable data.

He availed himself of the great shipbuilding program during the Civil War to make further experiments on expansion, on the use of superheated steam, and on the use of forced draft, to mention only a few of the many. The great value of this experimental information was so thoroughly appreciated by the profession that the results were published in book form by subscription.

Isherwood was a wonderful engineer. Loving him as I did, I may be pardoned for saying that I think he is the greatest marine engineer who has thus far appeared in our country. I fear that it is not appreciated as it should be, however, that he rose fully to all the responsibilities of his great office and was not only a great engineer, but a great administrator and executive.

When the Civil War was over he was criticized by good men who were engineers, but not administrators, on the ground that the machinery of our naval vessels during the Civil War was unduly heavy. They forgot, what Isherwood remembered, that his duty was not to provide the lightest machinery—with possibilities of breaking down in the hands of inexperienced men—but to provide machinery which would not break down and which would enable our vessels to be always ready to answer every call upon them. Many of the brave men who volunteered for service as engineers during the Civil War had little or no experience with marine machinery, and to have designed the engines which were to be entrusted to their care according to ordinary methods would have been almost certain to invite disaster. As a matter of fact, the machinery did not break down, was highly satisfactory, and carried our flag to victory. To my mind, this is one of the greatest glories of his career.

If time permitted I would love to go into detail about this remarkable man, telling of his broad general culture, his interest in art and music, and his remarkable felicity in the preparation of engineering papers. The older engineers in my audience know these things, and the younger ones can learn by reading what he wrote.

He retained his mental faculties in their full vigor to the very last, when he was more than 90 years of age. On one occasion, only a few years before his death, I was with a party of younger engineers who had called to pay their respects. We were all amazed at the wonderful range and accuracy of his memory, and even more at his intimate knowledge of the engineering questions of the day. His remarkable gift of fluent and lucid speech was strikingly evident, and we felt that we had enjoyed one of those rare treats where the wisdom of the sage is clothed in the elegant diction of the accomplished scholar.

A number of his friends and admirers, with the hearty approval of his family, believing that there could not be a more fitting place than the rooms of this Society for its permanent location, have commissioned me to present to the Society this portrait bust of the great engineer. Here, it is in fitting association with other busts, paintings and photographs of the leaders of the profession, many of whom were his contemporaries and by all of whom he was held in the highest esteem. And here, while engineers of the future gaze upon the features of this famous master in their calling, they may reflect upon his achievements which have added luster to the profession, especially as a great engineering executive whose genius contributed so essentially to the carrying of our flag to victory.

Dr. Hollis's Acceptance of the Gift

LADIES and Gentlemen, my old friend who sits on the stage, I accept this bust on behalf of our Society, to be placed in our little hall of fame that we may carry memories on to those who are going to follow us in this Society. It is with a certain amount of emotion that I personally stand here to accept this bust, because I knew Mr. Isherwood when I was in the Naval Academy, and I served him in a similar way, after graduation, as Mr. McFarland served him—the proudest service, perhaps, of my life, and one of my great memories is to have seen him and known him and known that charm to which Mr. McFarland has referred. I think of him as perhaps the father of our great research laboratories in engineering, as his investigations in connection with steam engines and with boilers preceded all of our schools of mechanical engineering.

I think of him also as the father of high speed on the sea.

Few people realize that it was Benjamin F. Isherwood who during the Civil War planned and carried to its completion the first ocean greyhound, a ship which went outside along the Jersey Coast and made four hundred miles in one day with ease, something that was not equalled again for twenty years. With a certain characteristic slowness in carrying things to completion, his ship, built to run down the *Alabama*, was not completed until the *Alabama* had been run down by another ship.

I think the rooms of this Society constitute a fitting place to put this bust as the example of a great man who can stand to us as a double father, the father in research engineering and the father of ocean navigation. I thank, on behalf of the Society, the family which has contributed this bust, Mr. McFarland who has made the presentation, and the small boy who has unveiled the bust, for giving us this treasure to be carried upstairs and placed in our rooms.

MANAGEMENT SESSION

Important Papers and Discussion on Some of the Modern Problems of Management, Including the Woman Worker in the Skilled Industries and the Re-education of the Crippled Soldier

THE American Society of Mechanical Engineers helped to contribute to the solution of war problems of the day by holding on Friday, December 7, an all-day session on the subject of Managament. The morning was devoted to the vital question of the Employment of Women in the Skilled Industries. A paper was presented by John W. Upp, of the General Electric Company, on the Woman Worker, and an address was given by C. B. Lord, of the Wagner Electric Manufacturing Company, on the Psychology of Environment. Invitations had been extended to manufacturing companies throughout the country to send representatives to the session or to outline their practical experience in the employment of women on the questionnaire prepared by the Society. Representatives from many manufacturing plants were present, who added to the discussion by relating the very interesting and enlightening experiences encountered by their respective companies.

The paper by Mr. Upp is here given in full, and is followed by the remarks by Mr. Lord and an abstract of the discussion at the session.

THE WOMAN WORKER

By JOHN W. UPP, SCHENECTADY, N. Y.

EARLY in 1917 it was necessary to materially increase our manufacturing facilities in one line in which the writer is particularly interested. It was evident that we could not obtain enough men employees to operate the equipment which was purchased for these increased facilities; we could see that this lack of sufficient men employees would continue and increase rather than decrease our difficulties; and we knew we could obtain men for our facilities only if we withdrew them from other manufacturing departments or companies which were occupied on actual or related Government work. After thoughtful consideration we decided to make a definite attempt to use women operatives instead of men on all classes of machine work. Our plans were made accordingly, and the accompanying photographs will give you at least a little conception of the work that these women are doing for us.

In our minds, and in yours no doubt, there has been a feeling that women are not suited to operate complicated machine tools or to do the work that is required in a modern and high-grade machine shop.

Presented at the Annual Meeting of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS, New York, December, 1917.

Thus the solution of the first problem, What can a woman do? would determine the measure of her value to us. The answer is extremely interesting and satisfactory, for we have found women under proper conditions and with proper training almost, if not quite, the equal of men on the work to which the women have been assigned.

We have been much surprised at woman's strength and endurance and are now willing and ready to assign her to duties which were until recently assumed to be entirely beyond the scope of her ability. She is remarkably quick to learn. With only a short intensive instruction many women are working at duties which we would only give to apprentices of two or three years' training.

We have found, however, that it is necessary to recognize some fundamental difficulties if women are employed in these unusual occupations. In considering her ability to successfully withstand work in the factory, it should be remembered that she is not so strongly built as a man, that she is not so tall, that her reach is not so great, that she cannot stand so long, that she is unsuitable for the lifting and carrying of heavy weights, and that she must have a great many conveniences that men do not require. Thus it has been necessary in all our machine operations to greatly change our methods of handling the work. This is so arranged and the carrying trays so constructed that it is impossible for a woman to obtain a load that is greater than 50 pounds, except where the size of an individual piece makes such a limit impossible. Stools or chairs are provided where possible and short rest periods have been found to be advantageous in many cases.

All the states have quite stringent regulations in reference to rest rooms and hours of employment for women. We have always felt that it was desirable not only to live up to the letter of such laws but to provide facilities beyond those which were required, because most encouraging responses have been made when we provided additional facilities and conveniences.

We do not feel that any employer should encourage women to work in his shops unless the conditions are suitable for such employment, and that a very serious error will be made if employers put women to work in the machine shops under conditions which men are willing to endure.

In hiring women, especially for tasks which are new to them, several points should reeeive their proper share of consideration so that both the company and the employee may benefit by the partnership.

Careful attention must be given to the character of the

women employed and more thorough investigation must be made of their references than in the case of men, for the employment of one undesirable woman will frequently destroy the usefulness of a large department. All the women working in any section must be acceptable to the other women or resignations with or without explanation will be apt to take place rapidly.

We also found early in our experience that women between the ages of 18 and 31 are more adaptable and learn more quickly than those who are younger or older—those who were younger than 18 not having reached a period of physical development which warranted their undertaking strenuous factory work, and those who were older than 31 being so fixed in their habits that they do not learn quickly enough to suit our purpose. In this experience, however, the employment of women has not differed materially from what it would be if we were employing men under the same conditions, for it is probable that if we completely changed the environment of men they would not be easy to instruct unless they were within the age limits specified.

WOMEN OPERATING SCREW MACHINES

We have not made any attempt to discriminate between unmarried and married women, except that we have investigated every acceptable applicant with minor children to assure ourselves that she had means of having her family taken care of while at work in the factory.

We begin to train a woman for her duties immediately after she goes to work. We never add many women to a department at one time, as we have found it impossible for an instructor to give to each of many new employees sufficient attention to obtain satisfactory results. If we take on too many women at once it is necessary for them to wait some time for instruction. In this interval they become discouraged, impressed with the thought that they will never learn, and usually nearly all those who have not been given the undivided attention of the instructor during the early days of their employment, resign, apparently having reached the decision that the work was going to be so difficult that they could never learn how to perform it. But when the new employee can be given the undivided attention of the instructor and can have the operations explained until understood, there has been laid the foundation for a probable permanent employee, and one whose work will in almost every case be satisfactory. We attempt to instruct two women at one time on each machine tool, giving them alternate opportunities to operate the machine tool themselves, but under the immediate and direct supervision of the instructor who is assigned to that particular job.

We found early in our experience that we had a smaller percentage of failures when our women employees came from the industrial walks of life, that is, from families in which the husband, brother or father was a mechanic. The women then understood many of the machine operations, particularly if they had a sewing machine at home or were familiar with modern household apparatus. If we drew our prospective employees from those walks in life where the men of the families were engaged as bookkeepers, clerks, or on similar work, the women had to receive much more instruction and they were more easily discouraged.

We find it difficult to teach women to operate screw machines, but when they learn, their work is as satisfactory as that of men; and on the lighter screw-machine work we are having the remarkable experience of finding their work more productive than that of men. We do find it difficult to teach women how to operate milling machines and we have had many failures, yet we have women operatives on milling machines doing high-grade work as efficiently as it can be done by men. We have found it difficult to teach women to operate lathes, but now have good women lathe operators in our employ. It has never been difficult to teach women to operate light punch presses, and although we have always considered heavy-punch-press work a man's job, we now have women operating heavy punch presses in an entirely satisfactory manner. We have always considered the assembly work on some of our more important operations as being essentially the work of the man who had been trained as a mechanic; but we now find that when properly instructed, women can do this work in a way that is entirely satisfactory to us.

TYPE OF CLOTHING WORN BY WOMEN ENGAGED IN SHOPWORK

It has been necessary to more closely supervise and inspect the work turned out by the women than by our regular run of men employees, for few women have any conception of the importance of dimensions, or any judgment as to mechanical strength or requirements. Therefore, they work by instruction rather than from any inherent mechanical knowledge. But you can be sure that once a woman employee is taught how to use a gage or learns what constitutes satisfactory work, the good work produced in the afternoon will be ex-

actly the same as that produced in the morning. The judgment which is frequently so disastrous on the part of our men employees will not enter into the work of the woman operative. She will follow instructions absolutely. Therefore, it is extremely important for the instructor to go into the minutest detail when he is outlining the character of the work.

We have found it very difficult to teach women the difference between a dull and a sharp cutting tool. But all the difficulties mentioned, as well as others, are within the possibilities of correction; and there is no inherent reason why the women of this country should not do most of the work in our machine shops, although regulations governing such work must be more carefully stated and followed than when men alone are employed.

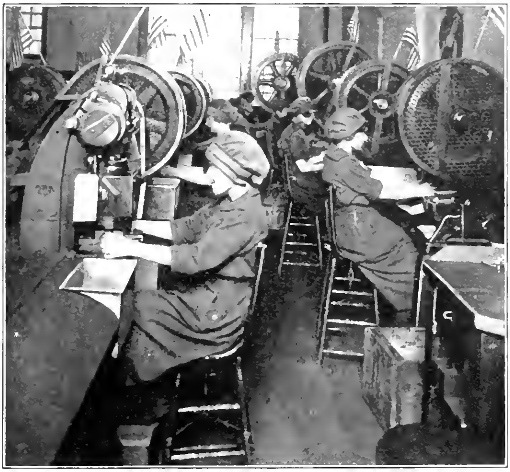
As a rule, the best results are obtained when the supervision of work is under the direction of men, although as immediate superiors of the women other women can be used to advantage.

When a woman begins to work in the factory it is of the utmost importance to impress on her the need of great care in the handling of machinery and also to explain that we are going to coöperate with her in keeping her free from accident hazards.

Difficulty with the clothing of women engaged in shopwork has been one of the most important problems we have had to solve, since loose sleeves, thin waists, skirts and unprotected hair are not safe in a machine shop, and to meet this problem we have encouraged the use of clothing more in keeping with factory conditions.

Women Operating Light Multi-Spindle Drills

When we originally adopted our plans there was some uncertainty as to whether we should ask our employees to wear the type of clothing shown in the accompanying photographs; and in order to settle the question once for all, the matter was submitted to the workers in a certain department for their own decision. We had had a few minor accidents due to loose sleeves, uncovered hair and loose skirts, and it was evident that in order to protect our workers it would be necessary to adopt some type of clothing which would remove that industrial risk. We arranged for a conference with our employees in the department mentioned and left to them the selection of the clothes which they should wear. We explained to them the reason we were increasing the number of women, that it was necessary to have these women to take the places of men, that we intended to employ more and more women in the future, but that we could not forgive ourselves if we permitted their employment to result in



Women Operating Light Punch Presses. The Wire Guards Have a Smaller Mesh than When Men Operate the Machines

accidents which might ruin their usefulness in future years. The conference was a most interesting one and the results were surprising; for of those who attended, 98 per cent voted, after a half-hour's consideration, to adopt the clothes which are illustrated in the cuts that accompany this paper. Of course, we do not ask or want our factory office employees to wear clothes of this type; they are only recommended and used in the factory proper.

Machines must be somewhat more carefully safeguarded if women are to operate them than if men were doing the work. In general, safety for women who wear proper shop clothes is provided by the same safeguards as for men, except that with wire guards it is necessary to make the mesh smaller so that the hair cannot get through and to place the guards farther from the moving parts.

The segregation of operatives has been given a great deal of attention. Until the present emergency we have made an attempt to separate our women employees from our men. We do now arrange to have our women employees quit their work a few moments earlier than the men so that the women can leave the factory without confusion, but we are making no attempt to separate them from the men in the manufacturing departments. They of necessity work on adjacent machines, for when the man who operates one of a line of machines is called to military duty we cannot move that one machine from its desirable location, but we can train a woman to operate it. Where the number of women in a department is relatively small, the desirability of segregation is most evident, and if it were possible we would segregate operations; but it has not been difficult to entirely control the situation by proper supervision, and now that our men are

becoming used to women workers, the interruptions and confusion have practically disappeared.

We have found in all classes of factory operations that women are more attentive to their work than men. They are more prompt, observe factory regulations in a better manner and, in general, are neater about their work, but we have not been able to impress them with the importance of being on hand every day. Many seem to feel that it will be perfectly satisfactory to be absent occasionally, particularly if they have any household duties to finish, and for this reason we have been careful to select those women who can be entirely relieved of such responsibilities if they enter our employ. Our record of absences of women is as a rule about 20 per cent greater than it is in the case of our male employees.

I have mentioned changing occupations in the manufacturing departments. We have also carried on a most successful experiment in the employment of women in one of the estimating departments. We have always employed many women secretaries, stenographers and clerks, but until recently have not found it advisable to employ women who were graduates of women's colleges in our commercial estimating departments, there having been a sufficient number of men trained in technical colleges to fill our requirements.

The withdrawals for military service, however, have practically exhausted our supply of technical graduates, these young men being the first to take part in military activities. We found ourselves, therefore, without a sufficient force to carry on our work, and, recognizing the situation, employed a group of college women, who are taking up the work heretofore carried on by the younger technical graduates. These young women had no technical training. They are, however, well educated and we selected those who had specialized in physics, chemistry, or other work of this character when we made our appointments. Then we immediately started an elementary course of instruction. The activity and interest of this group of young women is all that could be desired. They are more anxious to learn than the young men. The majority of them are not only anxious to earn their own living, but are most anxious to do some definite work which will release additional men for military duties. It is as yet too early to make definite statements in regard to what has been accomplished, but the situation is most promising and there is no reason to believe that our experiment will be anything but successful. This change cannot be brought about in a moment, however—there must be painstaking education and at the same time patience with inexperience.

As to the future, who can predict? Will the women we train on the work of men desire to retain their positions? It would be a wise prophet who could give a true answer at this time. But it would appear from our experience with thousands of women who have worked on the lighter machine-shop and assembly operations, that these women are always looking forward to the time when they can leave their industrial occupations and take care of a home of their own, and I do not believe that there will be any different condition after the war is over. The women who are entering our employ are prompted to do so because they are trying to do their part and because they desire to assist or supplement the family income. And it is probable that the larger number will desire to drop their factory work on the day that their husbands, brothers, or fathers return and are able to do the work for them

PSYCHOLOGY OF ENVIRONMENT

BY C. B. LORD, ST. LOUIS, MO.

PSYCHOLOGY, either accidental or predetermined, is the basis of successful management. Walter Dill Scott says, "The time has come when a man's knowledge of his business, if the larger success is to be won, must embrace a knowledge of the laws that govern the thinking and acting of those who make and sell his products as well as those who buy and consume them."

A knowledge of these laws enables us, when making rules, not to forecast with certainty, of course, but to make an inspired guess as to the effect of any cause in advance of its execution, and thus to lessen harmful experiments.

The part of this discussion assigned to me mentions environment only, but we must not forget that in this case environment has a direct bearing upon heredity, and that most of our troubles are psychological. When the wise man said that the training of a child began thirty years before its birth, he had in mind the physical wellbeing of its mother and the moral training of its father, for both of which, as employers, we are largely responsible.

As I see my duty, it is to secure maximum efficiency. This includes maximum average output, continuity of attendance and employment, a minimum of mistakes, and the anticipating of future requirements. If this entails analysis of mechanical requirements, a clean factory, and surroundings tending to cheerfulness and begetting modesty, than I am going to do all these things. If securing the desired results necessitated doing the opposite, that would I do. Therefore I want to disclaim any benevolent interest and put the matter on a practical dollars-and-cents basis. I can more readily do this, as it has been my experience that maximum of efficiency is secured by attention to the details just enumerated.

We find that contentment in woman is not induced by allowing her too great liberty of action, but rather in laying down strict rules for her guidance. When she becomes habituated to these rules, she accepts them as logical limitations and is content, provided always that they are just, equitable, and for her ultimate good.

Dissatisfaction with surroundings is a prolific cause of discontent. The same building, the same old stairs, the same rough bench and the same work contribute to this—unless the worker be sister to the ox—in mental fatigue. And as these influences are cumulative, a crisis is possible at any time, affecting maybe the individual only, perhaps the group or mass—trifles, perhaps, and yet such slight irritation has caused more murders and started more revolutions than has oppression. And so cheerfulness is an important factor.

The temperament of woman makes her acutely sensitive to color. She is influenced longer by the mourning she wears than by the loss of the departed. She also has an intuitive desire to decorate herself, and to be opposed to surroundings that satisfy the average man. This desire, carried too far, is destructive of efficiency, as is also an entire lack of it, but we can at least cater to her innate delicacy to the extent of having neatness and cleanliness. And so in harmony with this idea all machines that are operated by girls are painted with a white, oil-proof enamel, not as a fad, but to promote cheerfulness. Our floors are scrubbed, not impulsively, but regularly. Our toilets are clean, not disinfectantly, but soap-and-water clean. It would seem beneath the dignity of an executive to be responsible for clean toilets, yet it is indicative of his management.

Personally, I am tending more and more to the conclusion that the efficiency of men and women lies as much in their mental attitude as in their manual skill. I do not mean by this that contentment makes them skillful. It does not, but if they possess a certain skill, contentment enhances their productive output and lessens their liability to mistake, hence increases their efficiency.

Woman is more self-conscious, probably I should say sex conscious, than man. This is indicated by her inherent fear of men in general, and her equally inherent desire to attract man in particular. In this latter the decorative instinct comes into play and begets clothes consciousness. While it is common to both sexes, it is intensified in woman.

During investigations which I made as to the influence of wages on morality, I came to the conclusion that while there was no general connection between the two, where immorality did exist it was due to a desire, not for better education, or food, or surroundings, but for better clothes either to arouse the envy of her fellow-workers by outdressing them, or to mingle in society beyond one's means.

The point of all this is that no woman who is clothes conscious is efficient, and any woman who is either not as well dressed, or is better dressed than her neighbor, is clothes conscious. The obvious answer is uniformity of apparel, but with sufficient latitude to permit the exercise of individual taste. We have found the remedy by furnishing at cost an unfadable blue chambray. I want to emphasize the unfadable, for it is this that makes it successful, and as the waist is the most in evidence, and most abbreviated, we require a uniform waist and apron.

The success of the uniform depends upon an absolute enforcement of the rule. It is one of the peculiarities of feminine psychology that women will obey almost any rule, however disagreeable, if it is enforced impartially; but if favoritism is shown trouble immediately results. Having in mind the pleasure women take in showing their clothes, and also that they may want to go shopping on Saturday afternoon, we make it optional with our women employees whether they wear uniform waists or not on Saturday.

I mentioned as one of the features of my duties the ensuring of a future supply. Marriages in our plants average nearly two per month where both contracting parties are employees. These marriages are invariably successful because they are the result of observation, one of the other, under the most commonplace conditions, and not the result of proximity of one to the other, each in his best clothes and on his good behavior. The uniform waist is a big factor in this; it gives girls a clean-cut, neat appearance, with only the advantages nature gave them.

In some factories girls are wearing overalls, but I think it will be found that they, or the ones responsible for the decision, were rather masculine. In my estimation, this masculine tendency accounts for much of the feminist agitation of the present day; it also accounts for the increased efficiency of women, as the reasoning and point of view are more masculine. This type also lacks acute sex consciousness and looks a man straight in the eye, but unfortunately it also has the masculine moral aggressiveness, or I might say a lack of feminine retirement, and constitutes a dangerous element in the shop.

In an article which I recently wrote for *Industrial Management,* I described our method of combating this condition, and do not wish to reiterate, but I am reminded of Katherine Blackford's remark to me in this connection, that a man's passion is the dynamo that determines his ability; but of course, she did not mean that he has to violate the social code just to prove it.

According to Blackford, man may be classified by eight cardinal attributes, but for practical purposes woman may be classified as masculine, feminine, short- or long-fingered, phlegmatic or nervous, usually interchangeable terms, and sometimes blonde or brunette, for there is considerable wisdom in the maxim, "Send a blonde salesman to secure customers, a brunette to keep them."

In considering comfort and contentment we must bear in mind that fatigue may be caused by position, by improper form or height of seat, improper foot rests, or lack of them, awkward fixtures, left-handed girls on right-handed machines and other minor causes. These are all remediable troubles, but unless adjusted they cause girls to quit, and foremen to discharge them. It should not be forgotten that as the poor workman quarrels with his tools, so does the poor executive complain of the labor material at hand, and tells what he might do were it better.

I do not know whether or not the question of pay comes under the head of environment, but as much of it goes for clothes, perhaps it may be classed as such. It is a perplexing problem and one which must be settled locally, depending, as in other things, upon supply and demand. A woman is not as strong as a man, but is more dextrous; she has not the reasoning power of a man, but has a quicker mind. Where either of these attributes add to her ability, she should reap the advantage. Where piece rates are set, they should apply equally to both sexes, but when I am asked should she receive equal hourly compensation with a man, I must answer no, but she should receive as much as, or more, than a good-sized boy.

I will conclude as I began, by quoting Scott, who says, "Psychology is, in respect to certain data, merely common sense—the wisdom of experience, analyzed, codified and formulated."

DISCUSSION

J. N. Bethel, of the Taft-Pierce Manufacturing Company, said that his company most successfully employed in their surface-grinding department, 32 women surface grinders, who at one time were making for the Lanston Monotype Machine Company the molds for casting type, which called for a high grade of workmanship. Four of the machines were operated for several months on work that called for absolute figures with an allowable error of less than 1/10,000 in.

About twelve girls work on milling machines. They are not mechanically qualified to set up their machines, but when given good rigging hands and set-up men to set up their work, plus close supervision and careful instruction, they do very well, indeed.

Thus far girls have not been employed on the screw machines, but an alternative department is being installed to teach girls how to operate screw machines, also lathes and milling machines and cylindrical grinders.

Mr. Bethel was certain that female labor would be used to a much greater extent in his plant that ever before, and he believed that with the aid of the alternative department, girls would help solve the labor difficulties.

John W. Higgins, of the Worcester Pressed Steel Company reported that his company had been exceedingly successful and pleased with their experiment in using girls on press work in the manufacture of munitions, that is, on large cartridge

cases, helmets, etc., both on screw-machine work and press work, and especially in inspecting and gaging. They are deft, and uniformly more successful than men in these operations. Classes are being planned in the boys' trade school and girls' trade school for preliminary instruction for girls who have not worked in mills, in operations of inspection, gaging and assembling, and also to familiarize them with machine-shop methods and practice, especially with a view to their protecting themselves against accidents by teaching them the dangerous points of a machine, and also how they may conserve their strength.

Frank E. Blake, of the Remington Arms-Union Metallic Cartridge Company, stated that his plant had employed women for about forty years. In their new rifle plant, which was organized and equipped for men exclusively, and where up to a year and a half ago none but men were employed, 1300 girls and women are now very successfully employed, and very largely through the efforts of the 1300 women their output has jumped from 300 a day to 5000 a day. The women are employed in milling, drilling, polishing, filing, inspecting, and all of the operations in the shop which do not require man's strength.

A uniform has been adopted consisting of an apron and a net cap, which provides the ventilation that a closer woven cap would not give, and an apron of an approved design.

The speaker felt that the girls in the shops would stay there whether the war stayed or not. They have a place there, they are doing good work, and work that is satisfactory to the management. In one shop upward of 5000, and in the other about 1300, are employed.

L. W. Wallace, of the Diamond Chain Company, pointed out that the employment of women in the Diamond Chain Manufacturing Company was no experiment, as it had been done for 25 or 30 years. At the present time 30 per cent, or 300, of the factory force is composed of women. They are used successfully on punch presses, light and heavy assembling machines, automatic machinery of all sorts, drill presses, where they operate a gang of eight drills, and countersinkers, and on assorting, gage-inspection and assembly work. Women in the engineering office are doing drafting work. Two university graduates are in charge of the bonus department and cost department.

There is a woman called "Director of Mutual Service" who looks after the welfare of the women, their wage increases, their discipline, their discharges, their disputes. Through her the whole plane of the factory has been raised. Men and women work together, they check out on the same clock, get their pay from the same window, wash up in the same place. Profanity and obscene stories are absolutely barred, and because of that college graduates and high-school graduates are coming in and the general plane of the factory is being very much raised, and thus there is no trouble in attracting to the factory a high type of young womanhood.

Mrs. Harry E. Henstis, superintendent of women in the Ross Rifle Works, Canada, explained how the women of Canada volunteered as did the English women, and as the American women are doing, as munition workers, supplementing men for war service. They went in as machine operators, on drills and on all the other machines. There are three women experts in rifling. They set their own machines, grind their own cutters, and give an output in quality and quantity as high as any expert man rifler.

Miss Kate Gleason, Mem.Am.Soc.M.E., emphasized the fact that now the best class of women are attracted to the work in the skilled industries. In years past they were used on automatic machinery, which deadened their minds. Miss Gleason cited the case of a woman in Berlin, employed at the Deutschen Waffen Fabrik, who had been one of the many ordinary women employed there, but when the man at the head of her department had to go to war, she was given his place, and now is full of the pride and power of a real job.

Another woman in Rochester, forelady of a shoe factory, invented team work in shoe manufacturing. Through it her employer made a great fortune and it cut the price of shoes in two.

Major Frank B. Gilbreth brought up the question of the elimination of unnecessary fatigue.

This question of unnecessary fatigue in the industry is not to be confused with necessary fatigue. We expect workers to go home fatigued when night comes, we will insist on their having enough work to be fatigued when night comes. The proposition to be discussed is unnecessary fatigue. A fatigue survey should be made in each plant. A fatigue survey will bring out the fact, for example, that women use the wrong kind of chairs. Nearly all women insist on trying on their shoes before they wear them, but many in this country, certainly not one per cent, have had chairs assigned to them, with their names or numbers on them, and yet the necessity for that is perfectly obvious. The idea of assorting people by the top of the head from the floor, when it is the elbow that determines their length from a sitting or standing position, is ridiculous.

Major Gilbreth agreed with Professor Kimball, who, in speaking at the luncheon on Thursday, stated that mechanical engineering consists of almost everything in the world. He further continued, "I also agree with him on the psychology of management, and yet how little we act, from a psychological standpoint, having the employees and employers get in the habit of meeting on some subject, coming together during the period of lockouts and strikes, and if they would take this subject of the elimination of unnecessary fatigue as one typical case that they have no scrap about, and get in the habit of agreeing, it would be of great benefit."

A. W. Marshall related an experience with two damage cases against employers on behalf of girls who had had their scalps torn off on account of working near moving machinery. Such accidents can be very serious, and in both these cases the girls had their entire scalps cut off, and they were mutilated for life. Therefore it is of extreme importance that the women's hair be protected, either by caps, or by having the machinery amply protected. Both of these injuries were due to the fact that the shafts on which the hair was caught were charged with frictional electricity, which attracted the hair to them.

E. J. Poole took up several questions concerning the employment of women in the steel industry. First, in the matter of lifting, it was found that up to a certain point women were just as efficient as men. He told of an amusing incident of a man who was an employee in a wire mill who was continually complaining about having to lift the heavy coils of wire. One night his wife brought his supper to the mill and said to him, "Where are those heavy coils you have been complaining that you have to lift?" He pointed to them. They weighed probably from 10 to 70 pounds. She was rather husky and with

one hand picked up a coil and threw it on the reel. Immediately everybody began to chaff him and we have never heard any complaint from him or from any other man doing that same class of work.

As to the question of mixing nationalities, this should be done in order to avoid trouble.

On the question of wages, the system that has been very successful in England has been followed, namely, two-thirds of the wages of the men who are on that particular job. When the women become proficient they get the full wages of the men. If it is piece work they get the same piece-work rate that a man gets.

On the question of close work, in grinding for example, women do a great deal better work than men formerly employed.

Professor G. F. Blessing spoke of the research work done in Swarthmore College. Swarthmore College is a coeducational college, and it seems that the ideal we are striving for is to fit men and women for the same industry.

Professor Blessing described how fatigue-elimination day was observed at Swarthmore.

"We had our juniors in drawing and kinematics design fatigue-eliminating devices that might apply to their own work. For example, they would design a student lap board—that placed everything in a convenient and unique position. Another designed what he called a desk combination or help, on which he arranged all the things that he used in his ordinary studies in the most convenient place possible, and from that we worked along. In the shop we built a couple of Mr. Gilbreth's chairs, and we wrote to a number of the business and manufacturing men in Philadelphia to send us out such devices as calculating machines to be exhibited, and so we kept open house in the engineering laboratory during that day, and had all the students go through. In my class I had them write a report on conditions that they found wrong in the college."

Prof. F. R. Hutton, the chairman of the meeting, recalled the visit of the society to the Cash Register Company of Dayton, Ohio. The very best quality of women workers were secured by the simple means of allowing the women to leave the plant at five minutes of five so that they might have the advantage of going back in a trolley car from the cash register works into town a little ahead of the rush.

The following companies outlined their practical experience in the employment of women in the skilled industries on the questionnaires sent them: E. W. Bliss Company, Mergenthaler Linotype Company, Worcester Pressed Steel Company, American Locomotive Works, Brown & Sharpe Manufacturing Company, Hamilton Gear and Machine Company, Canada, P. W. Ellis Company, Limited, Canada, Canadian Fairbanks-Morse Company, Limited.

The Engineer, the Cripple and the New Education, by Major Frank B. and Lillian M. Gilbreth, was the next feature of the session. The paper is given here practically in full.

THE ENGINEER, THE CRIPPLE AND THE NEW EDUCATION

By FRANK B. GILBRETH and L. M. GILBRETH, PROVIDENCE, R. I.

THE purpose of this paper is to report progress in the solution of the problem of training the crippled soldier. At the present stage of the work we are able to formulate certain conclusions that have a bearing upon the activities of this Society and upon the part that the Engineer should take in the Crippled Soldier work.

These conclusions are as follows:

a The Crippled Soldier problem is practically identical to the problem of the cripple in general

b Its solution lies in a new type of education

c This education is destined to be the education of the future

d It is based on

(1) Finding the *one best way to do work*

(2) Adequate assignment to work, i.e., intensive vocational guidance

e The engineer is best fitted to determine the one best way to formulate it into methods, and to supply necessary devices and mechanical appliances.

All cripples, no matter what the cause of the crippling, require a training that will be mentally satisfying and physically beneficial. This training must be such as will enable them to become productive members of the community, and to remain on the world's payroll. This implies either competing with non-crippled workers in occupations open to all, or setting aside certain work for crippled workers exclusively, or both. It implies discovering and making available such opportunities for crippled workers, discovering which cripple is best fitted to utilize the opportunity, and training him to make the best possible use of it. It also implies not only opportunities for individual development, but such social opportunities as will enable the cripple to fit back into the ordinary social life with the greatest ease and the largest amount of durable satisfaction.

Those crippled in war furnish a small percentage of the total crippled as compared with those crippled from other causes, such as disease and accidents, especially in the industries. This is true even in Canada, which has furnished such a remarkable quota of fighting men in comparison with the total number of her population.

The solution of the crippled-soldier problem as outlined above consists of a type of education that is *new* in that it eliminates the greatest amount of waste possible in the educational process. It teaches *the one best way* at the outset, instead of following the old practice of "learn every way," with the vague hope of arriving at efficiency as an outcome. It enables the learner to arrive at a desired outcome with the greatest amount of speed and the least amount of effort, and with the largest return in efficiency and the resulting satisfaction.

This new method of education, discovered as a result of synthesizing measurements of champion workers in our *quest of the one best way to do work*, is spreading through the general interest in re-educating military cripples to the re-education of all cripples into the manual-training schools, corporation schools and the general educational fields.

Two Phases of the New Education

The new education has two parts: first, discovering the one best way to do work, and second, testing the individual and placing him at the demonstrated most appropriate work. By "work" we mean activity of any kind, whether physical or mental, for the investigations and the resulting methods are being made and applied in mental as well as physical fields of activity, as a result of our findings based on micromotion and cyclegraph records, which prove that the laws of habit formation apply equally well to mental and motion work.

The engineer is the natural person to whom the world now looks to find *the one best way*. This one best way is based

on accurate measurement not guesswork, personal opinion, bias, or the vote of a majority of a committee who have not measured.* The engineer's training in measurement fits him specially for doing the requisite work.

No Limit to Cripple Problem

To recapitulate, the *extent* of the cripple problem is, then, practically unlimited. When we come to consider the subject closely, we see that every one of us is in some degree a cripple, either through being actually maimed or through having some power or faculty which has not been developed or used to its fullest extent. The degree of crippling extends from the worker, who, through some accident, has lost his eyesight, his hearing, and the use of his legs, arms and hands except for the use of one finger—and, by the way, this is no imaginary illustration, as we have lately received a skilfully woven bag made by such a cripple maimed through a mining accident—to a man who is dependent upon glasses for reading. We can think of every member of the community as having been a cripple, as being a cripple, or as a potential cripple. Conversely, we can think of a badly mutilated man as not being a cripple during the period that he is at that work *the performance of which is not affected by the mutilation.*

As to the *nature* of the problem of the cripple, it is a problem of education, as has been said. *With the present state of the art of teaching, it is largely a problem of re-education,* since most of us, non-crippled as well as crippled, have received the wrong type of education, and must be re-educated even in the fundamentals. As education becomes more scientific, the problems of re-education will become simplified, and the process will become shortened.

Engineers Are Natural Solvers of This Problem

As to the natural solvers of the problem of the crippled soldier, these are, as before stated, the engineers, but only if the engineers will bring to the task the scientific attitude. As a profession, we have been too apt to be satisfied with half-way methods and half-way devices. We boast of the advance in engineering science, especially of the advances in the science of management, which have to date been, with few exceptions, the work of engineers, yet general knowledge and use of instruments of precision, even when such are available, are lamentably lacking. As a specific example of this, we may cite the use of the stop watch by experienced and earnest investigators in the field of time study. If the engineer, knowing as he must that it is an insurmountable barrier to obtaining *the best method*, or even knowledge of times that are transferable to others, is to discover *the one best way to do work*, he must use the best methods and instruments extant, and he must apply these with unremitting accuracy, persistence and patience. *The one best way* consists of elements of motions accurately timed and recorded, and synthesized into the best available method of activity.

If the engineers are, as a profession, ever to take the place that they should take in this work, they must start *now* to coöperate with those working in other phases of the subject. The various aspects of the problem are being assigned to those best able to handle them. For example, the task of making surveys as to what should be and is being done, and of the opportunities open to cripples, can well be undertaken by cities, towns and other civic organizations. This is being done, notably in Chicago, where we are assisting in the excellent work now under way under the leadership of Mr. Pike, Mr. Petterson, and others. The matter of furnishing money for the investigations and for the work itself is being excellently attended to by the Red Cross, as, for example, through the Red Cross Institute, New York City, with which we are coöperating, which has sent Dr. Edward Devine abroad for personal investigation and service in the field. There is also the work of Mr. McMurtrie, Acting Director of this Institute, who is collecting a bibliography on the subject of cripples. The matter of investigating the extent of the crippling and of providing the surgical and medical attention necessary is being admirably handled under the able leadership of the Surgeon-General and other Government representatives, already famous in the medical and surgical profession, in Washington. Too much credit cannot be given to Dr. Franklin Martin and Surgeon-General Gorgas for the progress that they have made in this great work in the short time since the day after the declaration of war, when they individually honored one of the writers by giving him an interview for the purpose of outlining possible work along these lines, since which time he has been honored by being appointed on Dr. Martin's committee reporting to the Council of Defense, and is now also coöperating with Colonel Owen and other famous doctors in the Surgeon-General's department.

The psychologists have appointed committees to investigate all branches of the subject that come within their field. The psychotherapists are working on their aspect of the problem, and Mr. George Edward Barton, of the Consolation House at Clifton Springs, Past-President of the National Society for the Promotion of Occupational Therapy, has spent years in theoretical and practical work concerning the convalescence period, and is contributing his experience and energies toward helping this cause. Educators are considering not only the training of the necessary teachers, but the training of the cripples themselves, notably Prof. Frank E. Sanborn of Ohio State University, and Prof. Wm. S. Ayars of Nova Scotia Technical College—the latter an American engaged for years in teaching in Canada—both of whom are members of this Society.

A Government Bureau Will Come

A Government bureau for collecting and conserving all these data will come naturally as a development of the activity in other fields, and of the present activity of various Government departments along various lines. This bureau should contain a museum that would include among its exhibits models of artificial limbs and appliances for cripples. This, supplemented by state and municipal museums along similar lines, would bring first-hand knowledge to the cripple, who too often buys the first artificial limb that he sees, and usually averages three or four purchases before he gets the one best suited to him.

Such a national museum should also contain fatigue-eliminating devices which would enable all workers to become more productive with less accompanying fatigue. The writers first called the attention of this Society to this need in 1910, feeling that fatigue study, like accident prevention, is a function of the engineer. We have, since 1913, started several small museums of devices for eliminating unnecessary fatigue, hoping that the movement would spread, and in the winter of 1915 tried to get the National Museum at Washington to start such a department, but apparently were not able to arouse much interest, though we were asked and thanked for a collection of wire models of motions. Recently Colonel Owen became interested, and now a definite start has been made.

The great need for fatigue elimination for the crippled soldier will undoubtedly lead to interest in the subject in this country as it has in England, for until recently we have had much more encouragement in our campaign for fatigue study from Englishmen than from our own countrymen. Mr. James F. Butterworth, ever ready to disseminate information relating to managerial economics, was the first to bring the matter to the attention of the British public. Prof. A. F. Stanley Kent incorporated his investigations of fatigue of munitions workers in reports, written by order of the King, since reprinted by this Government and obtainable at Washington. Prof. Henry J. Spooner wrote a series of articles on Industrial Fatigue in its Relation to Maximum Output for *Co-Partnership* (London), since issued as a booklet, which should be in the hands of every engineer and employer, and should also be reprinted by our Government and put on sale by the Superintendent of Documeuts.

The data for such reports and articles come from investigations of present conditions and realization of their significance. If the present chairs and work benches now to be found in all parts of this country, as well as abroad, were collected and put beside such efficient devices as the Barney chair and foot rest, and the Marshall traveling chair, they would look as out of place and cruel as do the devices of torture of the medieval period. Observing this, and with the cripple in mind, it will be noted that the principles underlying the adapting of chairs and foot rests to the industrial worker's measurements and to the needs of the cripple are identical.

Cripples Eager to Coöperate

This profession as a whole has not given the full benefits of its education, training and ingenuity to the industrial cripples of the past. The more we investigate the problem of the cripple, the more we marvel at their patience and the fortitude with which their calamities have been met and endured. They have made so few demands. They have been so pitifully eager to coöperate in this new work. They are, throughout the entire country, for the first time seeing the opportunity to do constructive work for their fellows, not only by showing what the maimed and handicapped can do, but by acting as examples of cheerfulness and continuity of purpose for all to follow. They are seizing this chance to do their bit for the war and for their country, and have shown such intelligent coöperation that we are led to agree with Mr. Fred J. Miller, Past Vice-President of this Society, that a man who has lost a limb becomes thereafter more active both physically and mentally.

Now the needs of our industrial cripples are supplemented by the more pressing need of the crippled soldiers. The crippled soldier is at a disadvantage, as compared with the industrial cripple, in that he is often at a distance from aid of various kinds at the time that the crippling takes place, and thus misses the chance for the early re-education that is desirable and necessary. Second, in that through mistaken kindness he is not taught work of any kind during his convalescence and during the period immediately after his return home; in fact, he is often encouraged by misguided friends to remain idle until the possibility of teaching the maimed member and the mind that has stopped learning, has decreased, and re-education becomes more difficult, if not actually impossible. Third, through the terrible physical and mental anguish that often precedes, as well as follows, the crippling.

The crippled soldier has the advantage over the industrial cripple in that he is the object of great interest and patriotic sympathy, therefore is a member of the community to be courted rather than shunned; in that he suffers in the limelight, and therefore is practically assured of assistance as soon as the world is convinced as to what he needs; in that he will have, if he has not now, expert training at his disposal; in that he has the consolation of fame and of having done something worth while, even though he had to pay the penalty of being crippled for having done it.

The Engineer and the Crippled Soldier

For these reasons it is advisable that the engineer turn his attention immediately to the problem of the crippled soldier, supplying the new education in the form of re-education for this soldier, with the assurance that when the methods and devices have been supplied, the industrial and other cripples will benefit exactly as will the crippled soldier.

We have already brought out, in papers on progress in crippled-soldier work, the various needs that must be met. One is the need of adapting methods and devices to the cripple, and another the need of adapting the cripple to existing methods and devices. The engineer has a part in meeting both these needs, that is,

a In inventing or adapting detached devices that will make it possible for cripples to do various kinds of work, such as various devices furnished us by the makers of the Remington, Monarch and Smith Premier typewriters, that enabled a one-eyed, legless, one-armed and one-fingered typist to write many more short letters in a given time than can the unmaimed champion typist of the world;

b In providing artificial limbs to replace those missing. Particular attention is called to the possibilities of inventing countless designs of articulated limbs controlled by systematized use of the trunk muscles controlling the joints of the limbs by means of wire and springs for replacing other muscles and tendons;

c In inventing or adapting devices that may be attached to the cripple himself, not to replace missing limbs, but in effect to supply new ones, i.e., additional limbs that will enable him to use existing equipment and thus accomplish work.

Use of Supplementary Limbs

Artificial limbs may therefore be supplemented or supplanted by what we have called "supplementary limbs," for examples, (1) a ring or loop attached to the suspenders or belt for assisting a one-armed man to handle a shovel, as suggested and used practically by Dean Cullamore of Delaware University; (2) yokes, special belts and grasping devices operated by pressure of the body against the work bench; (3) "the third thumb" for holding a magnifying glass.

Undoubtedly for all-around and general purposes it would seem to many people presumptuous to attempt to improve much upon nature in the question of the design of the human being. There is a resemblance here to our educational systems. Our educational systems are extremely good in many cases for all-around purposes, but they can be easily improved upon by any one who knows exactly what is needed for a special case. We therefore urge all who undertake this work of specially fitting the cripple to perform an activity not to hesitate to "improve on nature" at any time. This new viewpoint will help to handle many difficult cases. We hope soon to present a paper showing in detail practice of putting an extra number of limbs at the disposal of the unmaimed worker, a development of this work for cripples.

Simultaneous Cycle Motion Chart

We have been much assisted in adapting both devices and cripples by the use of our Simultaneous Cycle Motion Chart.[1] Through the elements there listed, such as "search," "find," "select," "grasp" and "transport," we have been enabled to invent or suggest, in highly repetitive work, some contrivances that are creating a new era in efficiency, as can be easily realized when the comparative simultaneous cycle motion charts before and after the investigation are studied. It is but necessary to call attention to the facts that all "grasping" is not done by the hand; that "positioning" may even be a function of the mouth; that the ordinary workman's apron with its many pockets may be used to relieve working members of the body, and that "inspection" for quantity and quality is by no means always a function of the eyes. There is an opportunity in "the device to handle the device" that will satisfy the yearnings of the most ambitious mechanical and inventive mind, a field almost without end that will eventually make the new era in industry date from the sacrifices of this war.

[Major Gilbreth here showed some pictures of methods and devices already in use, valuable as suggestions of what can be done along these lines.]

DISCUSSION

The paper called forth discussions so wide and varied that one speaker suggested that the objects of The American Society of Mechanical Engineers might well be redefined so as "to include every subject in the world." At least, the subject was taken up from many different angles and held the interest of a large audience throughout.

Col. W. O. Owen wrote that Major Gilbreth had struck the true note when he referred to the new education. It will be used not only for the training of the cripple, but for the training of the more active man. He will be taught to do his work in a better and more economical way, so that the fatigue of labor will be materially lessened. He approved of the suggestion that the motions of individual men who do their work better than their neighbors should be analyzed with respect to time, distance and motion, and said that if the best parts of these motions should be combined into a new motion the apprentice who learns this new motion will be able to do the work in shorter time and with less fatigue than those whose motions he has combined. He agreed with the author that the one best way seldom, if ever, exists in the consecutive-motion, cycle units of any one individual.

In speaking of the relation between the medical man and the engineer Colonel Owen wrote: "I believe that there is but one difference between individuals which makes one prefer to be an engineer and the other to be a medical man. It is purely a matter of receiving suggestions one on top of the other until an individual finally drifts into one or the other profession.

"I do not agree with Major Gilbreth that the engineer is best fitted to determine the 'one best way' or to formulate it into methods. I cannot help but feel that the medical man is the best fitted for these purposes. The engineer tried his hand, and a most expert hand it was, at Panama, some years ago, and failed, and I rather suspect that the engineer would have failed this time at Panama had it not been for a medical man coming to his assistance."

George Edward Barton[2] wrote that while the author's paper presents ideas that were new to many, the subject had occupied his entire attention at Consolation House for several years. In his work he was endeavoring so to combine the engineer and the cripple by re-education that, by making a virtue of necessity, the cripple was assisted to health and remunerative labor. This inevitably became a part of the work of the engineer and not of the doctor—or even of the orthopedist—for it was essentially treatment not by "physic" but by "physics."

To illustrate, he considered the case of a man who, as a result of shock, had what might be vulgarly called "a spasmodic sidewise jerk" of his arm, a case which he would analyze as follows:

"What have we got?"

"Well," says the doctor, "we have an hysterical condition of incoördination."

"D——n," say I. "That's a liability. What have we for an asset?"

"Nothing," says the doctor.

"But let us examine. What is it? What is this 'spasmodic sidewise jerk'?"

"Analysis shows that at least we have motion. Well, motion is of value throughout the entire industrial world, is it not?"

"What kind of motion have we got?"

"An irregular, intermittent, horizontal motion."

"Very good. Now, how can such a motion be used to the therapeutic advantage of the patient, resulting in some useful product? Or, if that motion cannot be so used, how can it be transformed into some other motion which can be so used?"

Mr. Barton continued: "All of us in the engineering world know that the problems of the engineer are essentially human problems; but those in the world who are not engineers regard his heart as being as hard and cold as that of the stone and metal with which he works."

W. S. Ayars wrote that the fact must not be overlooked in the problem of re-education that the raw material to be worked with is human. The task is not to select and train men for certain jobs so much as to select jobs for certain men, and then to train the man and modify the job so as to make them fit mutually. In the scientific selection and employment of men, it is admitted that one of the strongest points in favor of assigning a man to his job is the man's *appetite for the job.* It is all very well to make an expert typist out of a legless one-armed man who has a natural bent toward clerical work, but suppose he happens to have been an electrical lineman before enlisting, and had then lost two legs, or even one? Many such men have had their minds bent toward electrical work in general, and are agreeably surprised when they learn that there are plenty of branches of electrical work where the worker can sit at a bench and earn as good or better wages than they ever earned climbing poles and splicing wires.

Professor Ayars went on to describe the re-education work that is being done in Nova Scotia when the men return from Europe. First, in the convalescent hospitals, classes were organized in such work as boot and shoe repairing, automobile repairing and driving, novelty and jewelry work, etc., in addition to English branches and practical mathematics. This sort of work is vocational training.

What we call re-education is the intensive training given to men whose wounds or disabilities are such that they can no longer earn a living at the occupations they had before enlisting. Any man who is so disabled that he is entitled to discharge and pension, may come before a board consisting of at least one regular army officer, one medical officer, and a properly qualified civilian, and be passed for re-education,

[1] See Applied Motion Study, Sturgis & Walton Co., New York.

[2] Director, Consolation House (Vocational school for convalescents), Clifton Springs, N. Y.

should he so desire; and every effort is made to induce the man to do so. He must then decide what line of work he wishes to take up. He is given all the advice and help and encouragement possible, and is frequently persuaded, but never *forced*, to attack some lines of work that he had never thought of before. When he has made his choice, he can get his discharge and his pension, and in addition will receive pay and allowances as long as he is engaged in his re-education.

The Nova Scotia Technical College contemplates the following courses: drafting, garage or automobile mechanics, machine-tool operation, electrical wireman, steam-engine operation. These are intended for men of good common-school education, and others who can get enough of elementary mathematics in the vocational training classes before taking up re-education.

Then for men of mechanical taste, but not enough elementary education for any of the above courses, there is a course in boot and shoe making. This course will not turn out "cobblers" but real "mechanics in leather," and the progress made by some of the men is remarkable. In addition to all the usual hand and bench tools, there is a fine equipment furnished by the United Shoe Machinery Company, and the men are taught to build a shoe from the bottom up. As fast as they become skilful enough, they are given regular work and paid for it, the pay going into a fund to pay for a complete "kit," so that upon completing the course the graduate has a full outfit wherewith to set up on his own account.

Men who desire to take up certain other courses are accommodated by placing them in existing schools or commercial establishments where they can learn what they require. A course in janitor work is now being worked out for such men, covering the care and operation of boilers and heating systems, a little elementary arithmetic and English, and the simple knowledge of repairs to wiring, steam pipes and plumbing that a good janitor should possess.

One of the many difficulties encountered in this work is the fact that the men cannot be handled in anything like groups or classes. The work is practically tutorial: each man is a unit. They are assigned to the instructor each one in turn as he is passed by the board; they are of all "sizes," mentally speaking: what is hard for one man is easy for another.

Thus in the face of such conditions, how are we going to stop and apply Mr. Gilbreth's tests and studies? And where are we to get the men and the money to perform these tests? And how do we know that after A has been studied and tested for six months, and satisfactorily started on his course, that the data gained by such a test will have the slightest bearing on B, with a similar injury?

One point to be considered is the necessity for getting these men started *promptly*. Here again we encounter the difficulty of applying Gilbreth's personal studies and tests. Where shall we ever find the number of properly qualified motion-study experts to handle not dozens but thousands of cases?

It might be argued that a few specimen cases could be intensively motion-studied, and the data applied to all similar cases. It is conceded that motion study offers the best method of finding the standard way for a standard man to do any given piece of work, skilled or unskilled. But when the number of different possible injuries is considered; and the number of different possible personalities; and the number of different possible trades, jobs, or subdivisions thereof, then the number of permutations and combinations would startle the most hardened mathematician that ever lived, and the job of properly fitting the men to the jobs would require a small army of highly paid experts.

The work with the crippled soldier is very inspiring and congenial. The men are alert, cheerful and responsive; absolutely square and honest in their work, and with the unconscious courtesy and respectfulness bred into them by military discipline. They are likewise scrupulously neat and clean, always clean shaved, with clothing, buttons and boots in spotless order; all but two or three still wear their uniforms, and even those who have donned civilian garb have retained the little gold "wound stripe" on the sleeve, and always wear the little copper button of the returned soldier. A great many of them, to paraphrase from one of Gilbreth's other papers, will bless the day they were wounded, for already we have placed men who have finished their courses in far better paid jobs than they held before enlisting, or would have held at present had they never enlisted.

Prof. Frank E. Sanborn [1] was of the opinion that the work with the crippled soldier should be begun while they are still in the hospital, and as early as their nervous conditions will allow. The men have all left some occupation to take temporarily that of the soldier. As they lie in the hospitals and think of their wounds, they cannot but wonder how they are going to get on in the future, what they will be able to do for a livelihood. The outlook is decidedly blue.

There is nothing better to inspire these men, to cheer them up and to set their thoughts in a constructive channel, than to have brought to their attention those things which other cripples have done. These things can be illustrated by moving pictures and explained by talks. Information should be given about schools for their re-education for some occupation. These pictures need not necessarily be the one best way to do the work, but they will serve their purpose if they make the cripples hopeful and implant the thought that what one cripple has done another may do. When the men are able to begin their re-education along the lines of either their old work or a new occupation, what is more natural than to teach them the very best way of doing the work, a best way that is not entirely dependent upon someone's whim or say but a way that can be shown to be the best by means of measurements, scientifically obtained—measurements of motion, time, quality and quantity of output and fatigue.

In learning a way of doing work, the cripple or the whole man usually follows the motions of his instructor. These may be made so quickly that the learner can neither catch them nor visualize them. Until he can do so, he will make no progress. It is not enough or even right that the instructor go through the motions slowly, for slow motions are not in the same path as quick ones and a learner should learn the quick ones at the start. Therefore, pictures of the path desired are helpful and still more so are the wire models of the paths and the speed.

The Government is planning for reconstruction hospitals in this country and for re-education centers connected therewith. It is hoped that it will follow out the suggestions of the author and find the one best way for each part of an occupation and the one best way for the different classes of cripples, and have that way taught in the centers.

A. L. Curado [2] wrote of the willow furniture industry as affording a remunerative occupation for the cripple. It is an occupation in which a man sits while at work on a bench similar to a cobbler's bench. There is no machinery, the tools are few, the work is not too heavy and is very healthy. There

is a very great opportunity for creative work in this line of industry, as the uses to which willow may be put are innumerable.

In picking out an industry for a cripple, the willow furniture industry as well as any other, four fundamental factors must always be considered: (1) Can this work be done by a cripple? (2) Is there an economic value to the work? (3) Can the cripple compete with a non-cripple in the work? and (4) What about teachers?

Horace B. Drury[1] commended Major Gilbreth's power of seeing very vividly possibilities of which the world at large is hardly aware. He has given a tremendous stimulus to thought along the line of motion study. In its relation to the re-education problem a field has been opened in which, fortunately, there is no set order but in which it is possible and necessary to reconstruct rapidly and freely. There are a thousand different ways in which men are crippled and a thousand complexities of occupation to which they may or may not be fitted. There is no other way of approaching this problem except by charting and measuring, by gathering all sorts of data and by making the most careful study, all of which offers, besides, a great opportunity and need for comprehending the psychological and physiological basis.

Dr. W. R. Dunton, Jr.,[2] was greatly impressed by the author's desire to educate the industrial cripple, as the society of which he is president is at present perfecting an organization of individuals and social agencies to assist the industrial cripple in finding his proper niche.

Dr. Dunton went on to say: "If we could refer to a National Museum such as Mr. Gilbreth describes for labor saving, fatigue eliminating and prosthetic appliances, we would be spared much of the effort which we are now expending. In a recent inquiry concerning prosthetic appliances we were amazed to find how very difficult it is to obtain information. Here alone is a subject in which the engineer should coöperate with the surgeon. The latter's knowledge of mechanics, or even physics, is usually not so extensive that an engineer cannot give him much aid. On the other hand, the specialist in nervous and mental diseases can best appreciate that any effort which tends to eliminate fatigue from our daily lives tends also to decrease the waste of human energy, diminish the number of dependents, and generally improve economic conditions.

"Part-time workers would help to solve many of these questions. A convalescent from pneumonia, a heart case, or a neurasthenic is undoubtedly a cripple in the sense used by Major Gilbreth. Many such cases may be capable of a half day's work or a half hour's work four or five times a day. Two such men could make one day on a machine, so that the latter would not be idle."

Dr. H. E. Holsey[3] thought that from a psychological viewpoint the phrase "disabled soldier" would be preferable to "crippled soldier," as the latter implies entire loss of function whereas the former suggests the loss of certain parts that function but are not of necessity incapacitated or incompetent. Otherwise the author has combined his philosophy and his psychology admirably. He has understood the importance of satisfying the mental as well as the physical benefit. "It is one of the greatest satisfactions to the human that he can feel, though disabled, that there are ways by which he can remain on the pay roll of the world.

"To achieve extraordinary results, to cultivate efficient habit forming is the important part in re-education. To measure and guide the habit and give it character is the problem presented by the disabled human." Intensive education by means of micromotion produces such results. It is rapid and understandable and at the same time can be applied to the able as well as to the disabled.

Willard E. Hotchkiss[1] pointed out that too much emphasis could not be placed on the necessity of analyzing problems and finding out how to proceed before attempting to solve them. The Gilbreths' work in substituting photography and psychology for the stop watch and their development of motion study with the finer instruments and with the more intensive methods of analysis were cases in point.

Professor Hotchkiss felt that the phrase "the one best way" should have both a time and a subject-matter limitation, for the reason that the method which appears to be the "one best way" of doing a thing today may not appear so tomorrow, as a new invention in a field apparently quite remote from the one in which a particular process has been developed may entirely change the relevancy and effectiveness of that process.

Edward Cassidy,[2] who became blind some years ago, wrote that he has been able, nevertheless, to transfer some of his technical knowledge and experience to the blind in Massachusetts and from his connections with them he realizes the ever-growing need of the knowledge of the active-sighted man or woman. These people can be of help in securing for the blind a great many positions in manufacturing plants which they could fill successfully if it were not for the fact that the employers' liability act prohibits them from obtaining positions such as packing shoes in boxes, packing candy in boxes, pasting on labels, private switchboard operators, taking messages by telephone, timekeepers, even stenographers taking shorthand minutes of meetings—positions that blind people are amply able to fill. Mr. Cassidy is of the opinion that the time is not far distant, due to the ever-increasing blindness among our people, when business men will be forced to recognize the capabilities of blind persons and to secure for them self-supporting work.

Dr. F. L. Marshall[3] wrote he had discussed with the author the possibility of employing cripples in prophylactic dentistry and was led to believe from his experience in helping demonstrate that it was possible for a cripple with one eye, one arm and no legs to thoroughly clean a patient's teeth, and that this field would be adapted for the crippled. The manual dexterity and knowledge required for this class of work would not be difficult to acquire, and in a few months' time a man of ordinary intelligence should be in a way to become self-supporting.

Professor J. B. Miner called attention to the fact that Major Gilbreth's paper and his basic contribution to motion study suggested three ways in which the science of human behavior comes in touch with this important movement. The oldest of

these points of contact between psychology and the better adjustment of man to his work, is in the study of fatigue. The mass of accumulated data has recently been illuminated by Thorndike's experimental demonstration of the difference between the feeling of weariness and the decrease in output due to exhaustion which is only corrected by rest.

The second broad field, which is perhaps more worked by the psychologist than by any other scientist, is the study of the learning process. Dr. Thurstone has recently developed an equation for the learning process which promises to enable us to foretell an individual's limit of ability early in the practice curve.

The third point of contact is in the selection of men for particular jobs. Methods for selecting salesman, which have been worked out by the Bureau of Salesmanship Research at the Carnegie Institute of Technology have proved to be not perfect, but enough better than those previously used to cause them to be adapted to the purpose of selecting officers for the national army.

The rehabilitation of cripples will become a lasting contribution to all workmen. Groups of cripples afford a rare opportunity for experiments under controlled conditions which are so difficult to provide in normal industrial life. The importance of this strategic chance to study selection and learning problems under standardized conditions has been emphasized at present by the opening at Carnegie Institute of about the first school for training wireless operators for the army, as distinct from service in the navy or in the aviation corps. Thus far about 200 of the applicants for the school have each been tested for an hour by a carefully arranged series of mental and motor tests. In helping to improve the selection and training of wireless operators, there will be an opening for certain types of cripples which should place them in line for skilled work after the war.

John Younger dwelt upon Major Gilbreth's proposition that virtually we are all cripples, or conversely, there are no cripples. He went on to say: "It is an interesting philosophy to carry this out, and reason that man at present has actually crippled himself throughout the ages, and as a tool-using animal has actually improved on nature to the extent of providing himself with all sorts of extra limbs and organs. The telephone, for example, is in its fundamental sense nothing more or less than an extended ear, by which we can listen to conversations between New York and San Francisco. The pencil and the pen are peculiarly shaped fingers with which one can make marks. Man himself—the animal—cannot cut steel, but with the machine tools, etc., he uses, he has provided himself limbs whereby he can mold the metals according to his fancy.

"One great result of the work of Major Gilbreth and his colleagues will be that the cripple will no longer be relegated as an outcast. He will be treated as an honorable member of society, for just as there is no stigma attached to the manufacturer who is out of date with his deficient machine tools, so there should be no stigma attached to the man with deficient limbs.

"In order to deal with this problem constructively, each engineer, each designer should take his own particular work and see what he can do in his sphere to make his machine available to those crippled. It is possible to design very simply and very cheaply the slight modification to the existing motor truck, so that it can be operated by a legless man or a man with one leg, or a man with one arm, or similar variations."

Eugene R. Pike[1] related some of the experiences of the city of Chicago in its endeavor to re-educate its crippled citizens. An investigation and survey of the question was made with the object of determining the best methods that would serve the purpose, the probable expense of installing such methods, and also the securing of an estimate of the advantages which might reasonably be expected to accrue from the establishment of such methods of organizations.

Mr. Pike further continued: "During our investigations we found in one industrial plant alone, where an average of from 5000 to 10,000 men have been steadily employed, that the records in the office of the company's surgeon show that during a period of 30 years' operation there were 35,000 surgical cases resulting from injuries received within this plant. This indicates that one out of every seven or eight of the employees received an injury requiring surgical attention, and when the fact is stated that this plant is one of the modernly equipped plants in regard to safety appliances, we commence to realize what this question means to the average equipped industrial plant and the country as a whole. Most of these cases, we found, left the victim of the accident usually 'crippled for life' in some degree, ranging from the loss of a portion of a finger to the total loss of a hand, or leg; loss of sight in one or both eyes; of even the loss of several members, and in practically all cases it seems to be the irony of fate that the injured or lost member was the member that was chiefly relied upon by the victim in the earning of his living and the performance of his work."

The investigations have led to two conclusions, namely: (1) The problem should be handled as a re-educational problem along local lines, because local conditions vary throughout the country, but each local organization should coöperate with a national association of a similar nature; (2) the re-educational requirements of this class of work are very closely related to the present public-school system, in which manual training is provided for both young and old.

The Board of Education of Chicago has already under consideration a plan submitted by the Comptroller's Department that contemplates the use of technical high schools, and the employment of qualified experts for the following purposes:

1. The training of instructors in this new education and science;
2. The manufacture and instructions of the use of artificial limbs;
3. The adaptation of mechanical appliances to the adjusting of the cripple's remaining physical members, so as to replace those that were lost and assist the artificial limbs in the furtherance of physical functions;
4. The re-educating and scientific analysis of any crippled persons so as to fit them to do work for which they are best suited, mentally and physically, thereby still retaining for the use of the country the brains and ambitions that are not injured, for which there is an ever-increasing demand in industry.

The Department of Public Welfare of the city of Chicago has undertaken the making of a survey of the civilian crippled and the maimed of the city of Chicago, and also the making of arrangements for the placing of the re-educated cripple when he has been properly equipped and re-educated by the re-educational school in occupations of worth.

C. W. Rice outlined the work of the reclamation of cripples in France. The work is centered in the so-called National

[1] Comptroller, City of Chicago.

Office of Cripples and Re-Formed Men, an organization belonging to the Ministries of Labor, Interior, and War.

The work is carried on along very broad lines, and its importance is fully realized. After the war of 1870-1871 in France there were only a few thousand wounded and only 2700 men who had undergone amputations. It is estimated that in the present war by March 1, 1916, in all the belligerent countries there were about 3,000,000 cripples, and, in round figures, 10,000,000 wounded.

The professional re-education of cripples is based on the following principles: In the first place, all cripples are divided into two main classes; those capable of such re-education and those who must be taken care of by various forms of assistance, such as pensions, soldiers' homes, etc. The division is along purely economic lines; those capable of re-education being the men who, in spite of their crippled state, still represent a social value close to normal. It is estimated that about 80 per cent of wounded belong to this class.

The treatment of such people is divided into the following branches:

1. Purely medical treatment, in the widest sense of this term, with the view to bettering conditions.

2. Development of artificial organs to take place of those lost or incapacitated.

3. The invention or development of new tools or even new methods of production, so designed as to utilize the limited ability of the cripples.

The vocational selection, or, as it is called in France, industrial orientation of the cripples, which means direction of their efforts into lines where they may be most useful, together with means for finding jobs for re-educated cripples, forms an important part of these new activities.

The entire spirit of the work is to give men wounded in the defense of their country means to continue a useful existence and take part in the industrial life of the nation, and it is believed that this effort will be materially helped out by the great impending scarcity of labor throughout the world.

C. N. Underwood gave an interesting talk, illustrated by motion pictures, upon the remarkable case of a crippled employee at the factory of the Remington Typewriter Works. For thirty-seven years he was afflicted with sciatica and inflammatory rheumatism, and now he is a cripple from bust to knees, with the exception of his arms. After being given up to die by a council of five physicians, four of whose funerals he has since attended, he learned the trade of jeweler. Previous to his affliction he had been a machinist. He is now an operator in the experimental department of the works, and runs any kind of a machine. He works sitting or standing.

The motion pictures showed the man at his work as an inspector of typewriters, and also dexterously performing some of the everyday operations of life, such as dressing and undressing, for which purpose he has designed very clever devices. The joints of his body are rigid, so that he is unable to bend, and therefore he has devised tongs for picking up articles from the floor, for drawing on his socks, etc. He uses the point of his crutch for removing his shoes and socks. The crutches are of his own design. At the top is a ring on swivels which enables him to let go of the crossbar of the crutch and work at the machine without any danger of the crutch getting away from him. By letting go of the crossbar and supporting himself by his forearm on the ring, he can carry objects which he could not otherwise grasp with his hands on the crossbar.

Mr. Underwood said the man was not only one of the most skillful workmen in the factory, but one of the happiest, and the only thing that arouses his anger is the sight of some cripple begging.

Mr. Underwood also showed the rapid work of a one-armed clerk in sharpening his lead pencil, making entries from time cards on to schedule sheets, making entries in a small book, on tags, small cards, etc. He holds the paper on which he writes with the little finger of his hand.

Dr. A. Cullamore[1] held that the problem discussed by Major Gilbreth was not as simple as his treatment might seem to indicate. The problem in reality is twofold: first, training the cripple to function in the economic life of the community by making him capable of doing productive work and earning his daily bread; and second, which is perhaps of even more importance to the cripple, and to some extent to the community in general, making it possible for him to take his place in the social life of his community. He should be able to derive real satisfaction from life and to enjoy the fruits of his labor on a par with his fellows.

Dean Cullamore continued, "In training a cripple to earn his living, intense specialization is the keynote. We must not strive to ape or duplicate nature in any degree, but, as is pointed out in the paper, to find the one best way on the basis of merit alone. We must transcend nature in every case, and that is the job of the engineer. This is perfectly possible. One instance will suffice. The human eye is good, perhaps best, for general purposes; but when a high degree of specialization is desired, we turn to the telescope, the microscope and the camera. In this specialized work the man with two normal eyes is a helpless cripple—that is, from the standpoint of a cripple.

"What we want in vocational education is abnormality. Specialization seeks to produce abnormality along predetermined lines. Abnormality means specialization. Our problem is not to make a man normal, but to take advantage of his abnormality for his own benefit. These cripples are then forced specialists, that is, their specialization has been forced upon them. Therefore, let us treat them as such and see that we devise instruments to make their specialization commercially possible and profitable. That is our whole function in this regard.

"For years we have made clumsy attempts to equip men who have lost limbs in a way to produce normality, believing that this solved the problem. Nothing could be further from the truth. Economically, specialization or abnormality is success.

"Why not be scientific, and determine the equipment on the basis of the merits of the case. The wheelbarrow was invented for a two-armed man, with one wheel and two handles. The express wagon, however, has one handle and four wheels, and will maintain its balance. Our purpose should be to determine the case on its merits alone.

"Another point not generally taken into consideration is the change in the normal psychology of an individual which comes with the crippling. To every man who has been crippled two things must be shown which are of equal importance to him: first, that he can earn a living; and second, that he can enjoy the living thus earned normally with his fellows.

"The time to do this is before the psychological change has been formed—to forestall it rather than later to have to modify it. It should be done in the hospital, and it can be done by these moving-picture studies, if they are put across in the right sort of form."

[1] Dean of Engineering, Delaware College.

D. McMurtrie,[1] director of Red Cross cripple work, discussed some of the factors that must be generally taken into consideration in fixing up the cripple.

There are the human considerations. The war cripple is extremely discouraged at first, and the friendship and confidence of each individual must be gained before anything further can be done. He must be started along the right path by the right people. There are a good many difficulties in getting a man to come around to the position where he wants to go out and earn his living and do his full duties. Soldiers especially have been leading a life that is absolutely different from that of the civilian. They have been relieved of certain responsibilities, and have shouldered other responsibilities, so that when a man comes back who has been three years at the front, he has been where he has not had to think where his breakfast will come from, nor of where he would get his next suit of clothes. The first task will be to rebuild his initiative and his economic responsibility.

Another point is that the cripple's difficulties are not always of his own making, but are caused by the attitude of the community. First it pities him, and offers to extend charity instead of giving him a chance to hold a job. Until that attitude of the public changes, war cripples will have a very difficult time.

In considering the choice of trades for a cripple, the general principles to be followed are that the trade must first be a growing trade, not one in which employment is growing less rather than greater. It must be a trade that the man can follow in spite of his handicap, and it must be one in which he can hold not one job only, but a thousand. There has been a tendency in providing work for war cripples to devise special lathes and machines for the cripple; but if that is carried too far, a man who loses his position will be unable to go out and get another job in the labor market.

The man's former experience and education must also be considered, and if he is to be prepared for work that his past experience has equipped him for, he is being done an economic good. The day of the pension is past, and it is realized now that the first duty of the nation toward the returned man is not to pay him a pension, not just to entertain him and regard him as a hero, but to give him the best possible chance to get and hold a good job. Plans are now under way so that the American soldiers will be treated in that way rather than in the way that they have been treated in the past.

Fred J. Miller recalled a statement by a medical authority that a great many men who have amputations of a limb were thereby improved physically and mentally; that they were apt to be more vigorous and better men than they were before. The theory underlying this seems to be that the human machine was first devised for an entirely different life from that which we now lead; limbs were given us for the purpose of actively pursuing game by our own strength, running and leaping and tussling in a general way, and climbing trees. We do not do that very much any more. In consequence, we have an engine department, so to speak, consisting of the stomach, lungs and heart, designed for a different kind of work from that it now does; and if we amputate a limb, we have still the same department for producing energy that we had before, and the result is that a greater amount of energy is poured into the remainder of the body and evinces itself in greater activity. Mr. Miller cited a number of cases that he had found in confirmation of this opinion. He also believed that this had a bearing on the question of whether a maimed limb should be amputated or whether the surgeon should choose with the consent, and usually at the earnest request, of the patient to save the limb if he possibly could. He cited a case where a man's leg was seriously injured. He kept the leg: it was saved by skillful surgery, but was not much of a leg, and it bothered him a good deal for years and sapped his energy. He finally had it amputated, and he is in better health today than ever before. Thus from the layman's viewpoint, Mr. Miller said, there is perhaps too much anxiety to save limbs that have been injured when the patients would be much better off without them.

Dr. C. A. Waldo[1] pointed out that some method must be found to conserve, analyze and carry to a proper conclusion the valuable work in the re-education of the cripple that so many national organizations have begun. The value of the work of the efficiency expert and the importance of the investigations of the particular expert who, for mechanical ends, is trying to make man himself a better physical machine is self-evident. "Our human efficiency engineer is thus our best altruist, as he is never happy unless he is making his neighbor happier."

Obviously, in no direction at this particular moment can the services of the efficiency engineer be more welcome than in his efforts to rehabilitate and save the crippled soldier. There is a great volume of material already prepared along these lines, both at home and abroad. This material should be analyzed, arranged properly and in logical order, tabulated and indexed. It should be published by some nationalized center and should be distributed gratuitously from a national center.

The nation should be deeply interested in this work simply as an economical and paternal duty. We cannot at present reasonably expect to see the end of this gigantic struggle as victors until at least two millions of our men have been under fire. In that event, according to present statistics of casualties at the front, from three to five per cent of the forces will be disabled. If the number is placed at the average estimate of four per cent that would mean almost eighty thousand cripples. If the Government can partially or wholly restore these cripples to the productive ranks of society this would save a pension per man, say, of $250 per annum, or a total pension tax of $20,000,000 per annum or interest at four per cent on half a billion dollars, and as a result this army of 80,000 would be changed from a horde of dependents left to fade away in sickness, gloom and despair into a happy, contented group of cheerful, hopeful citizens.

Edward Robinson spoke approvingly of Dean Cullimore's suggestion that in the education of the cripple, not only should his vocational education be considered, but his general education as well, to fit him for the social life of the community. He regarded education as one thing and vocational training as another. The former is a general thing that takes a long time, the latter a specific thing that can be done very quickly with the aid of efficiency methods.

He was interested in the problem because of his connections with the University of Vermont, which he believed has received a request from Washington to prepare to take up the work of educating crippled soldiers, and he desired suggestions as to how a university could best handle the problem.

Dr. E. E. Southard,[2] speaking from a psychopathic viewpoint, said that he pretended at least to be a social engineer,

[1] Editor, *American Journal of Care for Cripples*, New York.

[1] New York City. Formerly Dean of Engineering, Washington University, St. Louis, Mo.
[2] Psychopathic Department, Boston State Hospital, Boston, Mass.

being a director of a psychopathic hospital. He pointed out how abnormal and unusual conditions have given educators opportunities to open new fields along educational lines and he thought that the crippled soldier afforded good material for study not only in the mechanical field but also in the physical direction. The study of mental disease is going to be pushed into general practice. Everyone is going to talk in terms of mental cripples and is going to realize what he suspected long since that he himself is some particular kind of mental cripple. He said:

"In working with the feeble minded it has been my problem to try to find, so to speak, the minimum amount of brains with which one could do the maximum amount of work. The schools for the feeble minded are precisely the places in the world where the best work is being done with the least brains. The normal school child is not being taught up to the normal, but the feeble-minded children are. We have got to work in that direction in the crippled-soldier problem."

From the viewpoint of psychology the speaker believed that Major Gilbreth's method of analysis corrected a fault of psychologists. These men do not believe that matter exists, or, at least, they do not like to talk of matter, which is tantamount to the same thing, and they, therefore, measure nothing but time, and all their work, therefore, appears to suffer from lack of measurement of space. The author not only points out the theory that we must make measurements, but he goes ahead and measures both time and space.

Dr. Southard took issue with the speakers who said that one of the great problems was to make the crippled soldier contented. There are many people who do not want to be contented. They take pleasure in being blue. There is no happiness that can be regarded as what we all want. In his experiences with psychopathic cases he had found this to be exceedingly true, and he believed that it would also be the case with the cripple. The primary emotions of fear, anger, sorrow and joy, as outlined by the behavorists, have each to be treated differently, for each reacts according to its inherent composition. Combinations of these emotions need very careful attention. At the Psychopathic Hospital he had had the opportunity to observe how differently people of the types mentioned above reacted in the face of certain stimulus.

In conclusion, Dr. Southard said that the work upon the deficient, upon the crippled, upon the people with the minimum of capacity, with the maximum output for that capacity was the big problem of efficiency, and it was the relation of the output to the amount of energy put in that would have to be studied along research lines from the viewpoint of sociology.

Miss Sarah Cox Johnson[1] emphasized the importance of the psychological side, which, she said, could be expressed by the homely old saying that you can lead a horse to water, but you cannot make him drink. Likewise we may prepare what we think is the right occupation or industry for a crippled or maimed man, with the aid of such expert advice and help as Major Gilbreth is able to give us, but all of that will miss its mark unless the man is saved from himself while he is in the hospital during the period of convalescence.

In a demonstration which Miss Johnson had been conducting on Blackwell's Island during the past year, she found the most difficult problem to be the human element—human emotions, the human mind. A man may come to the hospital and after having been relieved of the responsibility of earning a living and realizing that he, perhaps, may have to go through life maimed and crippled, must have his courage buoyed up and his self-reliance helped at the right moment, otherwise his despondency will settle into apathy and his apathy into a state of willing dependence and he will become thoroughly institutionalized. Here is where a woman's intuition plays an important part.

Alluding to the question of occupations for cripples, Miss Johnson said that handcrafts had generally been used. A great deal of misdirected energy was put into that field since people generally thought handcrafts to have been without craftsmanship. In so far as the craftsmanship is poor, the therapeutic value fails. It is important that in the hospital the occupations of the soldier should be taught by people who themselves are craftsmen, and in addition have a general knowledge of the facts of nursing and health, and a good grounding in psychology.

Whereas occupational therapy has been used for more than a hundred years, it has only recently begun to come into its own, and there are no places in the country for training teachers in therapeutics outside of the few institutions which have trained their own teachers. It will be of interest to know that Columbia University, Teachers' College, is the first college in this country to put in a course for the formal training of teachers along these lines.

Miss Edith M. Valet[1] spoke of the work of the New York Branch of the Association of College Alumni, which has recently offered its services as a committee to help the work of the Red Cross Institute. Their aim is to try to deal with the cripple in the ways Miss Johnson, Mr. McMurtrie and others have suggested.

David Beecroft[2] stated that for some time we have been confronted with the problem of the dilution of unskilled labor, which is closely related to the subject of handling the maimed, and as a consequence of the war both problems are going to demand our attention in the near future.

L. P. Alford suggested at this point that perhaps it would be well to redefine the objects of The American Society of Mechanical Engineers, as the session on management, with its discussions on psychology, physiology and allied subjects, showed, as Professor Kimball said, that mechanical engineering included everything in the world.

F. A. Hannah said that thus far the discussion on the subject had been from the point of view of the supply of cripples. He was interested in it from the point of view of the demand for cripples. As a consulting engineer, he had some clients who had anticipated a shortage of labor due to the draft and the demands of the Government for all employes who could be used on the special war activities.

Mr. Hannah further continued: "I have one client in particular whose business is well adapted to the use of cripples. He has a continuous process, consisting chiefly of machine-tending operations, which turns out a food product. The operations are comparatively simple and thoroughly standardized. We are now analyzing the operations on this machine and are drawing up certain specifications for a cripple. For example, we take a machine and we study it as carefully as we study men. We say that it should be tended by a man with one good leg and one peg leg, one arm with a good hand on it, twenty-five per cent of his sight and no hearing. Thus in a fairly standardized process we can go all the way through

[1] Department of Charities and Corrections, New York City.

[1] President, New York Branch of the Association of College Alumni, New York City.

[2] Directing Editor, *The Automobile*, New York, N. Y.

a plant and draw the specifications for every single operation on every machine."

Mr. Hannah then asked if anything had been done by the author along these lines.

Major Gilbreth answered that the simultaneous motion cycle chart was gotten up with the idea in view of showing all the faculties and all the limits of the worker, who is considered as a society of working members rather than as an individual, and thus a survey of the machine as a demand for motion and a survey of the cripple as a supply of motion will enable one to see whether the two coincide.

W. E. Symons also discussed the question, emphasizing the part women will play in the re-education of cripples and citing a number of his experiences with men who had been improved both materially and mentally by having been crippled.

Walter N. Polakov believed that the problem of the crippled soldier was absolutely inseparable from the problem of the labor market at large, and he thought that the Society, and Governmental and Red Cross institutions that are interested in the work, should submit the question to the labor organizations.

Arthur C. Jackson was of the opinion that it was necessary to create public opinion favorable to the employment of the cripple, and this could be done, he thought, not by having the deliberations of this meeting limited to technical publications, but by writing extracts for popular literary magazines which would create public opinion favorable to the employment of the cripple, so that it would be considered a patriotic action to place the cripple in a workshop especially prepared for his occupation.

Major Gilbreth replied to the salient points of the discussion, particularly emphasizing the fact that the crippled soldier is only a very small part of the crippled population of the country. The industrial cripples, the cripples from birth, from disease and from accident in reality comprise the problem that is ever growing in importance, a problem that includes wide and varied considerations.

MACHINE SHOP SESSION

Topical Discussion on the Subject of Inspection, Which Has Developed a Great Importance in Connection with the Matter of Inspection of Munitions

A SESSION was held under the direction of the Sub-Committee on Machine Shop Practice, Prof. Howard P. Fairfield, Chairman, for the discussion of one of the subjects most pertinent to the successful production of munitions—the subject of inspection. This meeting was arranged as a result of the unusual interest at the last Spring Meeting in problems of munitions manufacture which were discussed at that time; and in order that there might be a better understanding between manufacturers and government officials of the requirements of inspection and of its proper functioning with the other processes of manufacture.

The discussion was opened by three introductory talks: by A. L. DeLeeuw on the Logic of Inspection; by F. A. Waldron on the Relation of Inspection to Product, and by Colonel B. W. Dunn (presented by Major A. W. Erdman) on General Principles of Government Inspection and Relations Between Inspectors and Manufacturers.

THE LOGIC OF INSPECTION

By A. L. DeLeeuw, Plainfield, N. J.

Mr. DeLeeuw held that inspection is logical and necessary in our present mode of manufacturing, advantageous to manufacturer and inspector alike. Speaking first of interchangeable manufacturing, he said that while Americans had been patting themselves on the back because they thought they excelled in this direction, the fact was that the war requirements had shown that deficiencies existed in the matter of inspection.

Interchangeable methods of manufacture is a broad term, because it refers to two rather different things. Products can be interchangeable as far as design or use is concerned; or as far as individual details are concerned. For instance, it makes very little difference when we get a refrigerator of a certain size and make; whether it is this or that one or the other one. All of them will fill the bill equally well. So it is with a kitchen stove. In this sense refrigerators are interchangeable. To a certain extent even, perhaps different refrigerators of different makers are interchangeable. This is merely interchangeability of function.

But there is another kind of interchangeability. For instance, take the kitchen stove. If one of the lids breaks one simply sends to the maker for another lid which is interchangeable with the previous lid. Again the maker of pipe organs builds in groups or units, and he can build up a more or less complete organ by assembling a greater or less number of these groups. This is interchangeability of design.

On the other hand, two lathes of the same maker will interchange as far as use is concerned, yet may not fully interchange as far as the parts are concerned. He would hesitate to take a carriage from one lathe and put it on another and expect to produce a good turned-up piece. He would be rather afraid of doing the same thing with the headstock, or even with the spindle. He was not absolutely sure that he could do it with the leadscrew, although in some cases he might be able to. He would be more certain of replacing one of the gears with a new one but he was not quite sure that he could use the same key.

So here are different degrees of interchangeability: interchangeability of the entire product; interchangeability of groups and completed details; interchangeability of the pieces; and then interchangeability of the details of pieces, such as keyways, screw threads, and so on. In order to accomplish the highest possible in interchangeability, we must take up the matter of inspection.

The Beginnings of Inspection

The speaker then traced the development of inspection methods, beginning with the "olden times—not so very old either," when a complete machine was built and inspected by one man with the only criterion that it should do the work satisfactorily that was assigned to it. Later came the con-

tract system with the foreman as inspector; still later the system of progressive inspection where each workman was the inspector of the previous operation done by another workman; and finally the modern method where inspection is considered an actual operation in the production of parts.

As inspection became an operation in the shop, there was a natural tendency, also, to consider it among the burdens of the shop, due to the fact that "the man who holds the bag" likes to cut out things, but doesn't like to cut them in. While inspection as an operation makes it possible to produce on a large scale with less labor expense, this does not interest the man who holds the bag half as much as the fact that he has to pay actual cash to "fellows who take a lot of good stuff and throw it into the scrap heap."

Another thing that has set our minds against inspection is the fact that some fellow who can't even run a lathe and doesn't know the difference between a headstock and a tailstock, actually takes a piece on which an A1 lathe hand has spent two hours and says it is no good, and out it goes. Now, that is very aggravating. Nevertheless, we really ought not to blame the undertaker for the death of the man who is to be buried. If anybody must be blamed it should be the doctor. Neither should we blame the inspector if a piece is bad, although it is the inspector who buries it.

There is, however, some reason behind our dislike of the average inspector. There are cases where the inspector shows a woeful lack of intelligence. But if an inspector lacks intelligence, we should blame ourselves, because we expect something from him for which we do not pay. The man who does the detail inspecting for instance, takes a shaft, which he sticks in one end of the limit gage and then turns the gage around and tries it on the other end. If it goes on at both ends, he says it is no good. He takes another shaft and it goes on at one end and not at the other, and he says it is all right. That is all that that inspector is paid for. He is in effect an unskilled laborer who has been taught that one little repetition operation; and if one puts the proposition up to him to decide whether he should reject a shaft when it doesn't go in the gage, we are expecting from a laborer what an engineer should decide. If there is doubt as to whether the rejected shaft could not have been used, we should blame the man who set the limits or the man who made the gage, and not the inspector.

SPECIFICATIONS AND INSPECTION

Mr. DeLeeuw further said: "This brings me to the main point of what I want to bring out, and that is that the great trouble in the line of inspection is not so much with inspectors as with specifications, and in this connection I am speaking of the detail inspector who makes the interchangeability of manufacture possible. This is a serious subject, and it may not be amiss to tell a few of the things that are required of the inspector, for which he has absolutely no training.

"A few months ago I was in one of the biggest aeroplane factories in this country, and saw a man testing the long beams which form the main beam of the wings. These beams are of spruce, and generally speaking, are in the form of an I-beam. It receives most of the load. The man inspecting these beams had half a dozen laid out on a pair of horses. The beams were perhaps twenty feet long, and th horses nine or ten or eleven feet apart, a distance that might easily vary from day to day. The inspector laid the I-beam flat—not the way it was to be loaded, but flat. The man was very vigorous and took hold of the beam in the middle and punched it down three or four times. Sometimes it cracked before he got tired and sometimes he got tired before it cracked. If it cracked before he got tired he would throw it out, that is to say, he would throw it out if it was completely broken. Out of six that I saw him inspect, two broke and two cracked, but his ears were not as good as mine, he probably did not hear them crack, so the two cracked ones were passed along. Of course one can blame the inspector, but is not the real blame to be placed upon somebody above him who made him do this thing? Here is inspection without any inspection whatsoever."

Then, the speaker said, there is sometimes inspection according to specifications, which is a little bit worse. He illustrated this with anecdotes relating to specifications for belting which he said had been drawn up by the engineering force of some of the biggest concerns in the country, "not all the jokes coming from one concern." The specifications abounded in requirements which it would be impossible to check, as for example, that "all butts used in belting shall be of No. 1 selection; that the belting shall be of native packers' steer hide class; that the leather shall be stretched on straight-edged clamps; that centers and sides must be stretched separately; that the scarfing, joining and cementing shall be done by experts; that the finished leather shall be smooth to the touch on both sides; that the leather shall show no excess in the amount of material soluble in water or in ash, etc." Upon these he gave interesting running comments showing the futility of any specifications so phrased that it is impossible to check the requirements by a proper inspection of the finished product.

This kind of inspection, based upon indefinite or impossible specifications, becomes a matter of much annoyance when it relates to the finish of machine parts. "In a way we have grown used to a beautiful finish on various kinds of machines. The style of beauty varies somewhat. The style of beauty most appreciated in a self-binder, for instance, is a bright red with yellow streaks or green stripes; the style of beauty most appreciated on the bearing surface of a milling machine column, where a perfectly smooth bearing is wanted, is one which has spots on it and has been hollowed out by the use of a scraper. It is up to the inspector to say whether the finish of the machine or of the machine detail meets the ideals of beauty that the public has in its mind. It is exceedingly difficult for an inspector to do this without a standard by which to inspect; and yet I do not believe there are many shops that have standard pieces of finish which from time to time are renewed and inspected by the man who is to be responsible for selling the products."

STANDARDS AND INSPECTION

Another instance that had come within the experience of the speaker further illustrated the difficulty encountered where dependence had to be placed on the judgment of the inspector without an adequate standard for his guidance. He said in part: "A new machine was put into use for making a certain kind of screw heretofore done on another machine. As far as I could see the screws were all right, but the inspector promptly rejected the first one hundred. I sent them upstairs again with the request to hang tags to the individual screws showing which were wrong and which were right. Sixty-seven were wrong and 33 were right. I numbered the tags and made a list of those that were wrong. I got out another one hundred screws from the stockroom done on the old machine, and all inspected, hung also 100

tags on them, numbered them from 1 to 200, and made a list of them so that I knew exactly which were the old and which were the new. I sent the 200 screws up to the inspector and he sent them back with his mark as accepted or rejected, and I found that out of the 100 new ones there were now 33 rejected and 67 accepted; just the reverse of the other figures, and of the 100 old ones, which had once been all accepted, 75 were rejected. Now, that is the sort of thing that has to be checked. Really, the inspector was not to blame, because the ground on which he rejected them was roughness of thread. It is a very hard matter to say exactly twice in succession whether a thing is rough or smooth enough, especially when one considers that he may have accepted some of them Saturday morning and some Monday morning. There is a big difference there.

"One thing must be remembered when talking about inspection: Inspection does not aim at perfection; the aim of perfection is imperfection. Its aim is to make the imperfect serve the purpose required. We set limits beyond which the piece shall not go and set as wide limits as possible within which we will receive imperfection. Looked at from this standpoint, it will be found that the office of the inspector is not merely the office of a trouble maker but that he is really a useful member of society.

"The things that I have mentioned are merely surface indications of a great problem which we have before us. Most of us believe that inspection is absolutely necessary, but as a whole, the problem of inspection is still in the dark and we have not so far tried to put it on its feet. We have not, for instance, laid down standardized rules as to what specifications should be given, say on the drawings, to enable the inspector to do intelligent inspection without being a professor or a Solomon. We have got to the point where we are willing to make plus and minus allowances, but we have not got to the point yet where we are willing to make the plus and minus allowances as big, or, I should say, as convenient as possible, because the mere making of an allowance big enough does not always solve the problem.

"This is an engineering problem pure and simple. It is the problem of subordinating every piece and every detail, every dimension of the piece to our system of manufacture. Before the drawing is sent to the shop we should have a special inspection in the drawing room, going over every dimension with a view to subordinating it to the system of manufacture in vogue in that shop, and we further should scrutinize that system with a view to its being the most economical possible. There are certain things in inspection which make it more apt to be a failure than almost anything else. In the first place, it is a repetition operation. In the second place, there are many things the inspector has to inspect for which he has no absolutely definite data, and he has to follow his own ideas or notions. It is therefore necessary that the inspector should be controlled, and that his inspection should be inspected and checked.

"We ought to select our inspectors with great care. As a rule we can find them among our workmen. We sometimes find workmen who are not very productive just because their ideas are a little bit strict. Such men may easily be trained into detail inspection. We should try to get the chief inspector as broadminded as possible, but I do not believe it will ever be possible to depend on the broadmindedness of the detail inspector. There should be in the inspecting organization, either in your own shop, or among Government inspectors sent to a job, some man who is enough of an engineer, and also enough of a human being, to have the broadmindedness to look at things not merely from the standpoint of filling certain specifications, but from the broader standpoint of whether or not a piece is useful, because even in Government specifications there are cases where a piece may be useful and still might be rejected on technical grounds."

In conclusion, Mr. DeLeeuw spoke of the importance of gages, which, like the pieces they were to measure, should have limits, and should be checked by master gages verified from time to time by some authoritative source of the Bureau of Standards at Washington.

THE RELATION OF INSPECTION TO PRODUCT

By F. A. Waldron, New York, N. Y.

In continuing the discussion upon the subject of Inspection, F. A. Waldron mentioned that one of the disappointed contractors on munitions work, who had recently called at his office, had remarked that nothing could be said on "the relation of inspection to product," because no such relation existed. Another engineer had said to him that the relation of inspection to product was like that of son-in-law to mother-in-law, which suggested to him the possibilities of the subject. Then he began to think. While in every domestic circle there is the question of mother-in-law and son-in-law, if trouble exists it generally is on both sides; so he considered that, after all, the subject of his discussion was not as barren as it might seem.

Mr. Waldron said he would start at the beginning, aud, accordingly, indicated the necessary steps in the production of a commodity by the accompanying headings:

IDEAL
IDEA { Invention
       Engineering Design
DEMAND
MANUFACTURE
       Purchase
       Inspection

Imagination, which Napoleon contended "rules the world," takes form in the *ideal*, and ideals are what men fight for and what we are fighting for. The *idea* is the next stage to the ideal; one tries to make it approach the ideal. The idea is developed by *invention*, followed by *engineering design*. Then comes the *demand*. Before the thing is manufactured by any one there must necessarily be a demand, otherwise no one would manufacture. Following the demand comes the *manufacture*. Then follow two very important items: one being the purchaser, or *purchase*, and the inspector, or *inspection*. The purchaser desires some article and creates the demand; the manufacturer makes it, and the purchaser, in order to be protected, necessarily brings in the inspector to see that he gets what he is paying for.

The idea, as conceived by the inventor, becomes transformed into the design or engineering device. In the mind of the designer exists broad imagination; otherwise he would not be a designer. He conceives questions of space entirely from an academic standpoint. The question of whether it is ten feet or ten one-thousandths of an inch has no real definite meaning beyond the carrying out of the idea or invention upon which he is working. "There," he said, "is the keynote of the principal trouble in inspection, and the relatiou of inspection to product, simply substantiating what Mr. DeLeeuw has said."

Having established the design of a particular machine or piece of munitions, the question of manufacture comes up

where some of the biggest troubles occur; and in respect to these, Mr. Waldron said that as he had been both inspector and manufacturer he would try to be fair to both sides. He wanted to emphasize, however, that when a manufacturer who does not know what a snap gage is, nor what one-thousandth of an inch is, takes a contract for hundreds of thousands of duplicate parts, he is making a mistake. Under such circumstances he did not blame an inspector for "kicking" and compelling the plant to produce the goods according to specifications. Such action would do the concern good in the long run. One of the greatest difficulties in the way of the inspector is the manufacturer who is not familiar with the details of his business.

Relations of Manufacturer and Inspector

In the relation between manufacturer and inspector there is what one might call academic manufacture and inspection; and commercial manufacture and inspection. Academic inspection is where the inspector goes back to the original idea of the inventor and designer, neither of whom may have had any practical experience, and insists on absolute accuracy in accordance with the specifications. The result will be no product manufactured. This represents one extreme.

The other extreme is where the designer understands what dimensions mean; is one who can discriminate where thousandths and where ten-thousandths of an inch are required; who can visualize the processes of manufacture as he writes his specifications; and who is able to prepare the specifications so that the manufacturer and inspector can understand them. Under such conditions the inspector will be helped by the specifications rather than hindered, and if the manufacturer understands his work he will be able to turn out the product.

Trouble is sure to exist where the inspector and designer fail to get together, since the manufacturer, caught between the two, will be at the mercy of the conflicting functions. As an illustration, a concern which has been making hundreds of thousands of scabbards for the government had an inspector who was a specialist in scabbard leather, and as long as he was on the job the production was as regular as the clock. After some time this inspector was transferred, and another inspector was put on the work who had been a specialist in harness leather. Now, harness leather must have considerable grease content and bend easily in order to resist weather conditions and be flexible wherever it is used. This man cut open a piece of scabbard leather, and because it lacked the characteristics of harness leather he rejected all the scabbards. That was a question of the wrong viewpoint, but, fortunately, the difficulty was corrected by referring the matter to the man in charge of that division, who had the inspector changed to some other work. In the meantime the product was stopped for three or four days, which, with a production of ten or fifteen thousand scabbards a day, was quite a serious matter.

Conditions Rendering Inspection Difficult

The principal condition of design from the standpoint of inspection is to have reasonable tolerances determined in reference to the final functioning of the article to be manufactured. For instance, there may be certain conditions which have no effect whatsoever on the functioning of an article that must be held to very closely because the design so specifies. The inspector is helpless in such cases. It is only in questions of visual inspection that the personal equation of the inspector comes in.

The evil effect of too small tolerances in design goes further than the pocketbook of the manufacturer. It first of all reduces the number of pieces sent to the front for our troops; and in making that statement the speaker said he was not arguing for defective material.

The effect on the cost, however, is serious. The closer the tolerances the greater the cost of tools, gages and fixtures required to maintain the product, especially in the volume that it being manufactured at the present day. When the Government was ordering forty or fifty thousand pieces at a time, and only one order in two or three years, and they were being turned out in their own arsenals, it was easy to meet academic tolerances. But when turning out parts by the million and tens of millions, quantities unheard of before, the wear and tear on the tools and gages is enormous, and the making of gages is becoming an industry almost as large as our producing functions prior to the war. Enormous supplies of steel are required to replace the tools and gages which have worn beyond the limits of the small tolerances established by the department of design, or the engineering department, and we are in the economic position of a possible dearth of tool and high-speed steels. There is already a dearth of tool makers. A man came into a New England town recently and took away nine tool makers at $10 a day each and traveling expenses. Why did he do that? Simply because in some cases the design demands such close tolerances that it is impossible to furnish enough gages and taps and dies to keep up the production of the shop.

What the Inspector Lacks

While the inspector cannot be blamed entirely for conditions such as outlined, there are some other conditions for the existence of which quite a little blame can be placed on his shoulders. The solution would appear to be, as already pointed out, that inspection should be in closer touch with design—not necessarily in a functional or organization way, but in a "spiritual" way, if one so chooses to call it. Then the inspection department knows just how far it can go without having to refer back to the design. It knows what a piece is used for, and that if a thread is a little rough, but will go into the piece properly, no harm will be done. By such knowledge the inspector will be able to maintain an economic condition of manufacture.

On the other hand, if the manufacturer is trying to take advantage of the inspector and deliberately push through inferior or cheap work, it is then necessary for the inspector to put the screws on for the time being. Some inspectors will lay aside a pile of material, in the initial stages of a contract, for some minor defect; they will not pass it and the equivalent of a large sum of money may lie idle for a considerable time. After the manufacturer has had his lesson the inspector will then gradually take material away from the pile and accept it. Meantime the manufacturer may have lacked funds to meet his payroll. Where such conditions exist, unquestionably there is blame on both sides.

In conclusion Mr. Waldron said it was his purpose to try to bring out fairly the troubles of inspector and manufacturer alike so that in the subsequent discussion each might have his say, make their complaints, and in the end both might be able to get a little closer together, so that the spirit of the design might pass to the inspection department, and the mental attitude of the manufacturer be brought to such a stage that, instead of looking upon the inspector as a disturbing element, he would regard him as a helper.

GENERAL PRINCIPLES OF GOVERMENT INSPECTION AND RELATIONS BETWEEN INSPECTORS AND MANUFACTURERS

By COL. B. W. DUNN, U. S. A.[1]

In accepting the invitation of your Secretary to open briefly your discussion of this subject, it was not my thought that I could add any new facts to your knowledge of the subject. It was my hope, however, that I might succeed in some degree in preventing between our inspection service and our manufacturers at the present time a repetition of some of the misunderstandings that are known to have existed in the past between the inspectors representing foreign governments and our American manufacturers.

It is of the first importance at this critical stage in our history that harmony should prevail among all important elements engaged in promoting our national defense. Differences of opinion are bound to occur frequently between an inspector and a manufacturer. There is no reason why such differences should be at all serious when both parties are actuated by a desire to be just and reasonable. The differences have been most serious in cases where mutual distrust existed between the parties before the differences occurred. In many such cases this previous absence of confidence has been the principal cause of the difficulty. For example, it has been stated that the inspectors of a foreign government, while on their way to America, would drill daily on the steamer for the purpose of enabling them to detect dishonest practices that it was assumed the American manufacturer would adopt. About the same time these American manufacturers were assuming that the foreign inspector would be a grafter. Approaching each other in this spirit, it is not to be wondered at that serious trouble developed in many cases between these inspectors and our manufacturers.

Government Contracts and Inspection

It seems advisable to explain to you briefly the ordinary development of Government contracts and our methods of inspecting the product. The drawings and specifications for the desired product having been completed by the Design Section located at Washington, the next step is for the Purchase Section to select the manufacturers and negotiate the contracts. In the selection of these manufacturers, the Purchase Section is aided by reports from the Production Section relating to the equipment of manufacturers under consideration, their general standing, their technical personnel, their financial standing, etc. Competition among acceptable manufacturers is of course a controlling feature. The contract having been signed, a copy of it, with drawings and specifications, is sent to the Inspection Department and constitutes a notice to this department to take charge of the interests of the Government from that time on.

Our Inspection Department at the present time is made up almost entirely of men taken from the manufacturing industry. Any branch of the Ordnance Department is lucky at the present time if, in its personnel, it is able to show more than 1 per cent of officers who belonged to the Ordnance Department before the declaration of war last April. As a rule, the reserve officers are men who have come into the service purely for patriotic reasons. In accepting these patriotic offers, the preference of the Government has been for college graduates with the degree of mechanical engineer, and with a practical experience in machine shops after graduation of five years or more, during which the applicant has received a salary materially in excess of the salary paid by the Government for his grade. Many of these officers are now wearing the uniform and receiving a salary considerably less than one-third of their salaries in civil life. The assistants of these officers are civilian employees of the Government obtained through the Civil Service Commission.

The inspecting force at a single plant constitutes a field unit. It consists of one officer in charge, known as the Inspector of Ordnance, at the plant. He has as many assistants as necessary, consisting of junior commissioned officers, chief inspectors, assistant chief inspectors, and inspectors. To bring about uniformity in the action of these field units, we have a number of supervising inspectors, made up, as a rule, of men of large experience and mature age, combined with tact and good judgment. These supervisors have a number of plants assigned to them, and they circulate among them, charged with the duty of thoroughly investigating any complaints made by contractors and observing with great care the activities of inspectors to detect any weaknesses. Twice a month these supervisors meet the officer in charge of the inspection service at headquarters to discuss general features of the work and to promote uniformity in the action of the supervisors themselves.

From the above, it will be seen that any contractor who has the slightest reason to complain of the action of the Government inspector, can secure at once a complete investigation, and, it is believed, a correspondingly just decision. The inspector of ordnance in charge of the plant is required, in case of a complaint, to immediately get in touch with the chief inspector of the plant and to make a joint investigation. Granted that both minds approach such an investigation in the proper spirit, a satisfactory conclusion should be reached in more than 90 per cent of the cases. The supervisor should settle at least 90 per cent of the remaining cases, and when he cannot secure a settlement, only a few hours are needed to bring to the scene of trouble the principal technical assistant at headquarters, and, if necessary, the officer in charge of the entire service.

Differences Between Government and Commercial Contracts

It seems pertinent to analyze to some extent the differences between Government and commercial contracts. The most important one is believed to be the fact that a contractor cannot sue the Government. This is combined with the fact that in practically all Government specifications the contractor is required to satisfy the inspector. The manufacturer who considers an inspector unreasonable must be prepared to prove the accuracy of his charge. If we grant that an inspector is unreasonable, and possibly dishonest, and that his superiors belong to the same family, it is quite evident that the contractor is without adequate protection. The possibility that he may be placed in this position is a source of most of the manufacturer's imaginary troubles, which to him seem anything but imaginary. The absence of personal interest of the inspectors in completion of the contract is another difference between a Government and a commercial bargain. As a rule, the Government inspector has only one responsibility, that of seeing that the quality of the manufacturer's product is up to the prescribed standard. It is no concern of his that the product may be short in quantity. To stimulate produc-

[1] Inspection Section, Ordnance Department.

tion is the duty of another department, the Production Department.

Another very important difficulty to the manufacturer relates to the delays that frequently attend the receipt of funds from the Government. With millions to his credit, the Government paymaster cannot deliver the much-needed check until all requirements of rigid red-tape regulations are complied with. This is the cause of frequent trouble to the contractor who undertakes a greater volume of work than his financial backing justifies.

Another important difference is found in the fact that in commercial work the contractor is generally more accurately informed on technical matters relating to the product produced than is the purchaser. In the case of Government contracts, it is usually the other way. Few of our manufacturers are ordnance engineers, or have on their personnel staff men who understand the reasons for the requirements of Government drawings and specifications. The barrage fire, which constitutes such an essential part of military operations today, is seriously interfered with by any difference in the action of one fired round from another. Our soldiers will march confidently a short distance in the rear of this wall of bursting fragments, their lives depending upon this uniformity in the ammunition. Any material difference in the weight, exterior form, or location of center of gravity of the projectile, in the action of the fuse, or in the uniformity of the propelling powder charge, would be liable to cause one or more of these projectiles to burst well short of the intended point, and in the midst of, instead of safely in front of, our troops. The contractor who honestly thinks that some nicety of dimension called for by the drawings is introduced solely to allow the inspector to exercise his power, may, in this ignorant way, be objecting to one of the features essential to the efficiency of the ammunition.

Requirements from Government Inspector

The product of the manufacturer is divided by the Government into lots, and for each lot the Government inspector is required to sign a formal certificate, stating in substance that all units of the lot comply in quantity and quality with the requirements of the specification and drawing. It is impracticable for the inspector to inspect each and every unit for each and every requirement. The manufacturer does make a 100 per cent inspection of the product for all dimensions. The plan of the Government inspector is to check the manufacturer's inspection to the extent found necessary, the checked inspection for the more important feature being of course much larger than the less important. The certificate for the Government inspector is required before the voucher for payment of the contractor can be completed. As an illustration of the kind of coöperation that should exist between the inspection departments of the Government and the contractor, I am reproducing below two circular letters that have been issued from our Inspection Department to all contractors manufacturing artillery ammunition.

(COPY)

October 1st, 1917.

From: Inspection Section, Gun Division, Ordnance Office

To: (Name of contractor)

Subject: MANUFACTURERS' CERTIFICATE OF PERFORMANCE

1. It has been suggested that I request manufacturers to submit for each lot of finished product presented for official inspection a certificate on some convenient form signed by a responsible representative of the firm, and reading in substance as follows:

"I certify that Lot —— ———— —————— has been
(No.) (Article)
manufactured strictly in accordance with standard machine shop practice; that the components have been inspected carefully by the inspectors of this Company; and that to the best of my knowledge and belief this lot complies with all requirements of the drawings and specifications that apply to it."

2. Some of the arguments supporting this suggestion are:

(*a*) The certificate does not require any change in the present standard practice other than the signing and filing of the certificate.

(*b*) Very exceptional instances have occurred where over-zealous or dishonest subordinates have attempted to resort to questionable practices in repairing or salvaging defective material; and where their immediate superiors have disclaimed responsibility because they were ignorant of the practices.

(*c*) The responsibility of the firm in such cases will be acknowledged by no one more promptly than by the management, whose duty it is to take the steps necessary to avoid this ignorance.

(*d*) It is believed that this certificate will assist the management in establishing in the minds of all of its employees, and especially in the minds of its shop superintendents, foremen and inspectors, a correct appreciation of this responsibility. It is not conceivable that any of these responsible employees can remain ignorant for any length of time of anything relating to the work and practices under their supervision, if they make proper efforts to keep informed.

(*e*) The writer desires the establishment of the most cordial coöperation possible in the efforts of our inspectors and of the contractors to detect and eliminate all defective material, and to prevent errors of judgment in the rejection of good material. Mutual confidence is a necessary foundation for this coöperation. Suspicion will supplant confidence in any plant that does not detect and eliminate the employee who is inclined to conceal rather than to discover and report defects. If it is at all possible to correct the defects and salvage the material by proper, as distinguished from secret or questionable, practices, the Government inspectors will coöperate with the management to that end.

3. About the only criticism presented against the suggestion is:

(*a*) Any dishonest contractor or employee would not mind signing a false certificate, and the honest ones are liable to resent being asked to certify to their honesty.

4. Commenting on the above criticism, it is thought to be superficial. An honest man does not object to being placed on honor. Army officers have a just pride in their reputation for honesty, and they certify daily to the correct performance of various duties. The value of all these certificates is to a great extent educational. They concentrate the honest man's attention on important matters that require special treatment by him. In the production of ammunition for use by our soldiers on the firing line, the prime responsibility to conserve the safety and efficiency of the ammunition rests equally upon all concerned with the production, and all agencies tending in any degree to promote this conservation should be utilized.

5. Please give this subject your careful consideration, and let me have the benefit of your views.

(*signed*) B. W. DUNN,
Lieut.-Col., U. S. Army, Retired, Commanding.

Letter No. 2

November 21st, 1917.

From: Inspection Section, Gun Division

To: (Name of Manufacturer)

Subject: MANUFACTURERS' CERTIFICATE OF PERFORMANCE

1. In a former circular letter I asked for comments on the suggestion that we require from manufacturers a certificate similar in substance to a certificate signed by Government Inspectors. While some of the replies reflected some doubts as

to the necessity for such certificate, the suggestion did receive the hearty approval of the majority of the manufacturers.

2. This correspondence indicates that the certificate should be signed by the Chief Inspector in the employ of the manufacturer and countersigned by the Shop Superintendent. The original suggestion was indefinite in this respect, and stated that responsible representatives should sign the certificate. It is evident that the Chief Inspector and the Shop Superintendent are the chief representatives of the company who know most about the actual work in the shop. A slight change is advisable also in the wording of the certificate, substituting "good" for "standard" in describing machine shop practice.

3. General William Crozier, Chief of Ordnance, whose attention was invited to this correspondence, suggested that good results should also follow the placarding of his plant by the contractor with notices inviting attention to the obligation that should rest upon each individual employee to do everything in his power to insure that the product of his plant is of the proper quality to insure the safety of our soldiers and our success in the war.

4. I am therefore inviting manufacturers to submit for all lots of their product completed, after date of receipt of this letter, the following certificate:

> "We certify that Lot ——— (No.) ———— (Article) has been produced by the use of good and modern plant practice; that the components have been inspected carefully by the Inspectors of this Company, and that to the best of our knowledge and belief this Lot complies with all Government requirements that apply to it.
>
> (*signed*) ....
> *Chief Inspector for* .... *Co.*
>
> *Countersigned by* ....,
> *Shop Superintendent.*"

5. It should be understood that the above Certificate is not required of any manufacturer who prefers not to furnish it. When furnished, it should be forwarded directly to this office through the Inspector of Ordnance at the plant.

(*signed*) B. W. Dunn,
Lieut.-Col., U. S. Army, Retired,
Commanding.

It is my hope that this discussion will result in developing other practical methods for promoting this coöperation.

DISCUSSION

Sir Charles Ross said that two months ago there had been criticism in this country of a matter in which ammunitions were concerned. While it was not to the point of the meeting he desired to take the opportunity to say that after 16 years of close study of the American Government's Ordnance Department he was filled with admiration for it, and if the details of the ammunition question had been known to the public he felt that the work of the department would have been applauded instead of criticized.

Speaking of the troubles and difficulties which arise between inspectors and manufacturers, he said that he would propose a solution as a basis for discussion, so that if the fundamental theory on which it was based should meet with the approval of the engineers of the Society some practical means might be worked out for accomplishing the desired results. At present there is no means by which the inspection department of the Government can have matters explained to it by some quite impartial persons; and if the manufacturer has complaints to make the odium is at once thrust upon him of making complaints in respect to the inspector, which is a very undesirable thing to do.

In order to overcome that unjust obligation on the manufacturer, the thought is that an independent body should be created, called *X*, in the diagram below. Such a body might be composed of the elected representatives of the engineering societies of America, whose functions should be as follows: (1) to hear the complaints of both the manufacturer and the inspector; (2) to advise both the manufacturer and the inspector, and (3) to make reports to the Secretary of War and the Secretary of the Navy.

PUBLIC OPINION
PRESIDENT
CONGRESS

SECRETARY OF WAR }	X	{ SECRETARY OF NAVY
MANUFACTURERS }		{ INSPECTOR-CHIEF

The speaker believed that such a plan would secure the coöperation of and be welcomed by the Government. With such an organization, questions of proper toleration and finish, questions of samples, etc., could all be passed on.

At a later point in the meeting he presented a resolution for the appointment of a committee whose duties should be as outlined in the foregoing discussion. This finally led to the drafting of a resolution as given below, which was voted upon favorably.

Resolved: That the Council of the Society be requested to recommend to the Government the creation of a Board which shall be intermediate between the manufacturer and the inspector, and the Secretaries of War and Navy—the functions of this committee to be as detailed in a resolution offered by Sir Charles Ross and unanimously recommended, viz.:

That authority be given to a committee as follows:

(1) It shall hear complaints:
  (a) From manufacturers.
  (b) From inspectors.

(2) It shall advise inspectors as well as manufacturers upon the proper application of gages and standards of acceptance and rejection.

(3) It shall report and have access to the Secretary of War and the Secretary of the Navy.

R. H. Danforth pointed out that while the question of gage inspection is undoubtedly the question of most importance to those concerned with machine-shop work, difficulties are encountered in the inspection of material which could have been partly eliminated if there had been preliminary inspection. The parts which depend primarily for their acceptability on machining do not usually depend on the material, except in so far as the material determines the usability of the products. To illustrate, a manufacturer of small tools, taps and dies purchased steel under usual specifications and had made practically all of it into taps which were heat-treated and hardened in the usual way. Customers complained that the taps did not wear. An examination showed that ten per cent of the taps were not hard at all, and a chemical analysis of the soft taps proved that instead of being of tool steel they were of cold-rolled stock that had gotten in by mistake.

Another instance was in the manufacturing of automobile parts and drop-forgings, which have to be heat-treated in order to provide the necessary strength with the minimum of weight. A great deal of difficulty was encountered in getting alloy steel within a reasonable tolerance of composition so it would be amenable to heat treatment. In one case a shipment of fifteen-point carbon steel was mixed in with a lot which had been ordered as a thirty-five-point carbon and fifteen-point vanadium steel. After heat treatment, instead of getting 75,000 lb. elastic limit, only 40,000 lb. was obtained. As a result the manufacturer put in a complete inspection department for his raw material. He bought in lots of from 50 to 100 tons and made a chemical analysis of at least every ton.

A great many specifications today are practically impossible to meet. They call for certain chemical requirements and also for certain physical requirements, and unless the latter have sufficient leeway to allow for the maximum allowable variation in the former, or unless the former have an allowance sufficient to take care of the maximum allowable variation in the latter, one cannot produce material with proper characteristics. Thousands of specifications in use today do not take that point into consideration, and therefore are a constant source of trouble to both the manufacturers of the raw material and the finished product, to say nothing of the inspectors who act as the go-betweens.

W. S. Huson said that while we are working for the standardization of products and the standardization of production we are also awakening to the fact that we must have standardization of inspection. This is all the more important, as Mr. DeLeeuw pointed out, because of the kind of labor which must be employed, but the thought had come to him that it is not so much the inspection itself that must receive attention as it is the specifications; particularly for the guidance of the younger inspectors, who lack the necessary experience. Drawings and blueprints should be made to convey intelligent information to worker and inspector; and care should be taken in the designing of a machine to avoid useless and needless precisions.

He further said: "In discussing the broad field of inspection I believe that common sense is not a bad thought to give expression to. The inspector must feel that he is not hidebound by the instructions and the pictures that he has. He must use some gumption and common sense of his own.

"The chief inspector must communicate to those who are under him those qualities which govern proper and intelligent inspection. The day has gone by when 'jacking up' men is the thing to do. A man must be agreeable, even if only in a subordinate position such as that of a junior inspector. He must try to judge the work without bias or partiality and must steer clear of two things: he must not permit the workmen to agree among themselves as to what constitutes the quality of work they turn out, and he must avoid getting into argument with them as to whether it is right or wrong. He must go to the chief inspector, who must be intelligent and efficient enough to know what constitutes the right kind of work, and how far the tolerances can go one side or the other. In other words, today the principle of good shop inspection is not to point out why work is wrong, but rather to try to point out to the men why it should be right, and thereby gain their cooperation."

As contributing to this, the speaker raised the question as to what had been done for factory organizations similar to that which is being done in other fields by technical journals and house organs. Have we to any extent given to the men engaged in manufacturing operations the "whys" and "wherefores" of the work that a machine does, of the products produced and their requrements? While some workmen would profit by such printed matter, others would undoubtedly not, but nevertheless he felt that some consideration should be given to the development of such means of communication to at least show the workers that their services are appreciated.

Forrest E. Cardullo contended in answer to Mr. DeLeeuw that a set of specifications could not be gotten out that would cover entirely, completely and satisfactorily what was needed. No man had sufficient foresight to cover everything that would come up in materials and workmanship and various other things that affect the usability or non-usability of parts. The Constitution of the United States is a set of specifications for government, and there are about 110 volumes of interpretations of it. One cannot prepare a set of specifications for a motor, including materials and parts, or for an aeroplane or a gun, and cover it completely. Room has to be left for the inspector to use his judgment, and the inspector that does not is one of the best allies that the Kaiser has. The inspector should be given authority to waive the specifications. For example, it is all very well to say that a thing should have no surface defects, and it is wise to follow out this specification if the defect of the part is such that it affects its suitability for use. If there should be a tiny sulphur seam in the main bearing of a crankshaft of an aeroplane motor the crankshaft should be rejected, but if the defect is in the crankpin of a certain type of motor the pin should be accepted. In short, it all depends on whether the thing is just as good for use as if it met the specification in every respect, and if it is it should be accepted.

The war cannot be won by specifications or by inspectors. The only things that can do it are guns, ammunition, aeroplanes and various other agents of destruction. The purpose of inspection must be to produce the largest possible volume of military implements and munitions that are suitable and usable for their purpose, and the inspection that fails to do this is radically defective. In his connection with the Curtiss Aeroplane Company the speaker had heard young men in the American Inspection Service say that it was immaterial to them as to what the product was or whether, for example, ten or sixty aeroplanes were produced per week, as long as they saw to it that the "stuff" met the specifications; and if because of that attitude on their part production was delayed, it was unfortunate, but it was no concern of theirs. Such an inspector is a grave danger to the country. The purpose of the inspector should not be simply to reject certain pieces that pass on one side of an imaginary line, and accept certain other pieces that fall short of a certain imaginary line; but it should be to keep up the general quality and quantity of the product.

Inspection should be reorganized on the basis of quality and quantity. We are apt to fall into error in believing that our inspection has to be complete. Our inspector, whether connected with Government or plant, should bear in mind when he is inspecting the product of outside manufacturers that he is there primarily to help bring up the general quality, and when he has reached that point he has then done his duty.

Philip Reynolds[1] stated that he had been connected with ammunition manufacture from three different standpoints; from that of government inspector, the manufacturer and the shop inspector. He had worked on Russian and British work since the crack of the first gun. He had seen pictures of guns that had burst, with all the men either killed or wounded, just because some inspector used too much judgment. He believed that inspectors should live exactly up to the requirements, up to the gages, and that they had no right to use their own judgment at all. Matters of judgment should be submitted to their chief.

Coming down to shop work, he believed if everybody worked on restricted tolerances, that is, lower tolerances than the Government required, there would be very little trouble. He had had no trouble in meeting Russian and British requirements. The boys at the front must be protected. There must be no "prematures," or anything like that taking place.

C. B. Hamilton, Jr., also from Canada, endorsed the re-

[1] Supt. of Inspection, Lymburner, Limited, Montreal, Canada.

marks of the last speaker, and said: "We have been in this war longer than you have, and we are having our boys come back minus arms and legs, and we don't want any of that done with our own shells. We have been accustomed to the barrage fire for some time, and we are beginning to realize the niceties that are required in shell work to make sure that we are not going to have some shells burst in our own ranks; and shell work is only one of the items. There isn't any 'good enough' in this munition business. There have been quite a number of us finding that out, and you people will find it out, too."

With regard to tolerances, he said that it is the practice at his plant to make the limits in the earlier stages of the work less than the government requirements, and to increase progressively as the latter operations are approached until finally they equal the government requirements. If the limits in the early operations are made as wide as they may be, there will be trouble all down the line. The limits in the early operations should be as close as the men can work, even if it costs more money. The money will come back by less trouble in the secondary and later operations.

Mr. Hamilton said that it is further the practice in inspecting materials to do as Mr. Danforth suggested. In some cases analysis is made of a specimen from every half ton of steel, and in a few cases every bar is analyzed. Discrepancies are not all due to accident by any means. A lot of plain, ordinary negligence existed on the part of steel manufacturers.

In this matter of specifications we had better assume that the man who wrote the specifications knows more about the work than those who are just starting the work. The modern progress of shell fire calls for closer and closer limits. We will be working to closer limits next year than we are now. While the production may be reduced, we must have shells that will produce results in Germany and not in our own ranks.

He felt that the specifications quoted by Mr. DeLeeuw with regard to belting must have been selected in a way that gave a wrong impression. There are two kinds of specifications: guidance specifications and inspectors' specifications. The specifications such as Mr. DeLeeuw read are in the nature of guidance specifications, for the manufacturer to take into consideration in bidding, to know whether he is going to be able to produce that kind of goods. The inspector has nothing to do with such specifications.

While he did not want to be misunderstood in referring to things made in the United States, he had been told that shells had been sent to the British Government that were so rough that the revolution or spinning of the shell made the steel act as a rotary file on the explosive block, and produced premature firing.

In response to a question by Mr. Cardullo, he said it had been found that there were a large number of premature explosions among shells that are rough, but when they are polished there is no trouble from that cause.

Major A. W. Erdman said that as far as the Inspection Section of the Gun Division of the U. S. Government is concerned, the contractors are expected absolutely to live up to the specifications as they are written. If there are any points in the specification that can be advantageously changed, if they are called to the attention of the department the officers will be glad to coöperate with manufacturers, but the Government must proceed along these lines. It cannot proceed on the theory of getting a general average of good product.

Philip Reynolds advanced the theory that such explosions, which sometimes shattered the guns, killing every man on the crew, were due to faulty fuses rather than to the cause advanced by Mr. Hamilton. Mr. Cardullo also confirmed this opinion, saying that the consensus of opinion among those at the front was that the cause of premature explosions is defective fuses.

C. E. Coolidge reported that he had spent two strenuous years in the manufacture of munitions in Canada, and had gone over about as many of the hard spots as any of his confreres. Fortunately, his plant, one of the largest in Canada, was located in a district where there was a broadminded chief inspector. They had a large contract for eight-inch howitzers, and they probably had as much reason to find fault with government inspection as did similar plants, but the policy adopted was a broad one.

It was recognized at the start that they must first of all protect the boys on the firing line; secondly, they must protect the government; and thirdly, they must protect the manufacturer. This must be accomplished through a spirit of coöperation all around. While it is an ancient tradition that the operating and the inspecting organizations must be arch enemies, with a sort of dead line between them over which neither must step, such a spirit can produce only unsatisfactory results. It is the policy in this particular plant to consider that the government inspection corps and the shop inspection corps are practically one.

The speaker said that he had organized the shop inspection corps and had made it plain to every one of the inspectors that they were part of the government staff, and also advised the chief inspector for the government to take under his wing to a certain extent the company's inspectors. In that way they constituted one happy family. In order to overcome ill-feeling between inspectors and the machine operators, inspectors were assigned to each machine and they were told that they must be friendly to the operators and should coöperate to the limit. The spirit in that plant is of this kind. Every one feels that he is doing his little bit, and each one that he is the man behind the man behind the gun.

Charles E. Davis had found that when the fact was established in the minds of the inspectors that the truth was wanted from whatever source it could be derived, friction disappeared and production increased. He had found this to be particularly the case in connection with fuse construction for the British Government. Their assistance on many questions was needed and invariably when a point was reached where there was a question in regard to the product, they were told "We want to make this test, and we want your inspector with us when we make the test." They coöperated and gave every opportunity, and the result of their experience at every point, and the percentage of loss was reduced to a very low percentage. To his mind it was first necessary to establish in the design of a piece or a machine the vital functioning points of the product to be produced; then to establish the limits of variation that will give these results reliability. Hold to them rigidly. On non-essential points cover the matter as carefully as you can.

Major A. W. Erdman said that inspecting the functional points as outlined by Mr. Davis, was exactly the line along which their Inspection Section was working. For instance, on the twenty-one-second time fuse he thought there were 45 distinct metal parts, and there were something like 240 gages required. In the factories which have had years of experience in making these fuses the government was inspecting with thread gages to be sure the fuses would screw into any shrapnel.

Philip Reynolds[1] wrote that from his experience with the manufacture of Russian and British shells he believed that in the inspection of munition quality could be held to the set standard. As for quantity production this also could be obtained granted that the manufacturing department was tooled to perform each operation with the human element reduced to a minimum and with positive stops and machines which are kept up, combined with a perfect sequence of operations. The inspection must be organized so that the product of each machine is safeguarded thus preventing the possibility of a run of bad work.

In connection with the above Mr. Reynolds outlined the organization of his plant, as follows:

The superintendent of inspection has chief inspectors for each eight hours' shift, with their assistants controlling each floor or battery of operations. Gaging is performed at the back of machines, the work being conveyed by gravity to inspection bench. Care is taken in the allotment of the quantity of machines for each inspector. All prime dimensions received 100 per cent inspection. Final shop inspection is not necessary with efficient machine inspection except to check parts which are liable to be affected at subsequent operations. All machine inspection is made with restricted tolerances, ensuring the acceptability of work by government with their larger limits. This method has proved must successful. The superintendent of inspection is responsible for quality of product to the general manager.

The superintendent of inspection is held solely responsible for the quality as the shop superintendent is for production, all differences being settled by the general manager.

Each inspector is provided with a small personal stamp which he or she stamps on a location allotted by the government inspector and which does not interfere with the product. By this means any faulty inspection is traced. The assistant inspector checks up his inspectors frequently. Given limit gages which are right, inspectors have no excuse to wrongly gage. All gages are checked daily and twice daily, where necessary, by the gage and standard department, who are held responsible for a sufficient supply of gages and their accuracy. The head of this department is the chief draftsman and he reports direct to the general manager. This complete system of inspection has proved very satisfactory in meeting the conditions which exist in the plant.

The writer thought that interchangeability applied to a machine or a mechanism was the attainment of producing standard units of mechanism which guarantee without selection the assembly of the machine. To illustrate, a projectile and its component parts are designed with limits which allow of shell fuse and cartridge case to assemble without selection. It therefore seems correct to assume that it is practical to maintain interchangeability in munitions without sacrificing the quantity of production.

R. F. Bryant[1] contributed a written discussion, which will be published in full in the next issue, covering the experiences of the Yale & Towne Manufacturing Company regarding several important phases of inspection, particularly of fuses.

PUBLIC MEETING OF GAGE COMMITTEE

Culminating in a Proposal to Government to Cooperate in Munitions Contracts by Requiring Certification of Gages by Bureau of Standards

REPRESENTATIVES of important Government departments, both Army and Navy, the British Ministry of Munitions of War in the United States, the Canadian Munitions Board, leading munitions manufacturers and makers of gages, met at the call of the Joint Committee on Gages of The American Society of Mechanical Engineers and the Society of Automotive Engineers on Tuesday afternoon, December 4, not for a technical discussion, but to consider in a broad, patriotic way what could be done to accelerate the manufacture of munitions and to provide means by which all munitions, wherever manufactured, should be interchangeable. Costly blunders in the handling of the gage question by this country during the Civil War and by foreign countries during the present war were responsible for serious delays and loss of effectiveness.

The Chairman of the joint committee, Harry E. Harris, President of the H. E. Harris Engineering Company, presided at the hearing, and called upon Major L. A. Fischer, in charge of the Gage Design Section of the Ordnance Department, to state the purposes of the meeting by reading a brief résumé of the work of the committee up to this time.

Inception of Society's Gage Work

This phase of the Society's war work had its inception at the Spring Meeting in Cincinnati last May. So clearly was the vast importance of this matter brought out by extended discussion that a resolution was adopted calling upon the Council to appoint a committee to coöperate with the Government in laying down a sound foundation for the tremendous munitions-manufacturing program upon which the country was about to engage. Representatives of the Society sent to Washington at the time, however, found that immediate action would be premature, but two months later conditions were considered sufficiently favorable and a committee was appointed. At a meeting on August 23, the committee agreed that there should be one central bureau for the certification of gages, and that the best place for such work was the Bureau of Standards at Washington. The inspection of all master gages should be made at the Bureau of Standards, but, if possible, some of the working and inspection gages be tested in the vicinity of the factories making munitions, or at the plants of the gage manufacturers. This meeting was followed by visits of the members of the committee to such department officials of the Government as were particularly affected by and interested in the question of gages. In general, these officials expressed their entire approbation of the plans of the committee.

Society and Government Officials Get Together

In order to get a concerted understanding in the matter, the

Society gave an informal dinner to a number of high Government officials and members of the Council of National Defense, following which those present joined in a general discussion of gage certification and standardization, displaying considerable unity of opinion and appreciation of the work the Society was endeavoring to do. While many phases of standardization were considered, especially as applying to raw material, manufactured products, and gages, the discussion centered around the absolute necessity of having all gages made to the same standards, to insure correct standards and interchangeability.

Following the dinner, a letter was sent to all present asking that each department concerned appoint a member of its staff with whom the committee might confer in working out a satisfactory program. This letter was well responded to by the various branches of the service. As a result, the committee now has serving with it official representatives of the principal departments concerned. The coöperation of the Society of Automotive Engineers has been secured in the form of a committee to serve jointly with our committee. All are agreed that standards of measurement, master gages, reference gages, inspection gages and Government inspection gages should be certified at the Bureau of Standards so far as is physically possible.

At a meeting in Washington, on October 30, it was ascertained, through correspondence and representatives of Government departments present, that many of the departments were conforming to the recommendations of the committee in having gages certified at the Bureau of Standards, that there was close coöperation in many instances, but not according to any universally accepted plan. It was recommended that the various bureaus recognize officially the Bureau of Standards as the technical source for the certification of all master gages, and as many of the inspection and working gages as possible. A sub-committee was appointed to prepare a clause for the consideration of the full committee, which could be incorporated in all Government orders for gages, and in contracts for war supplies in the manufacture of which the supplier would be required to make or purchase gages. Such a clause was submitted to the joint committee on November 10, and has been the subject of much discussion and correspondence. All comments and suggestions were considered at a meeting on Tuesday morning, December 4, and a final form adopted for submission to the Government departments if approved by this public meeting.

Gages Must Be Checked Against Standards Under Unified Supervision

Chairman Harris stated, in further explanation of the work of the committee, that while a proper handling of the gage situation was of the utmost importance at the moment in securing certain supplies, such as airplane motors, truck engines, guns, small arms, ammunition, etc., the committee had no intention of proposing that on other material, such as fire buckets, for example, orders and specifications should require the sending of the gages to the Bureau of Standards. In order to produce war supplies of a mechanical nature on a large scale, in widely distributed plants, that will be correct to specifications, interchangeable and function properly, it is an established fact that universally correct gages must be had, and that the only way to have them uniform is to check them against the standard of measurement under unified supervision. Hence the recommendation that all gages be made to the standards of the National Bureau of Standards. This involves no change from existing standards, but insures the correct duplication of existing standards under the direction of technical experts equipped with instruments of precision such as few factories possess. Referring all gages to this central agency for verification would also prevent duplication of measuring equipment and technical staff, thereby conserving our most valuable resource, skilled man power. In conclusion, Mr. Harris called upon all present to unite in the single purpose of assisting the Government, setting aside private interests, desire for profit, prejudice and selfish pride, remembering that the recommendations made by these two great engineering societies, representing the vital forces of mechanical engineering in this country, would command the support of manufacturers, Government officials, the general public, and receive considerable attention from Congress.

Important Gages To Be Certified by Bureau of Standards

The Chairman then called upon Mr. William A. Viall, Secretary of the Browne & Sharpe Mfg. Co., to read the clause proposed by the committee, which in its final form is as follows:

> The master and reference gages and standards of measurements, with which are to be compared the gages and measuring instruments used in carrying out this contract, are to be certified by the Bureau of Standards of the Department of Commerce, Washington, D. C.

The committee also proposed the following form of memorandum to be used by heads of various Government departments in notifying the branches and officers under their jurisdiction of the adoption of the Bureau of Standards as the official agency for gage certification:

> The Bureau of ———— designates the Bureau of Standards of the Department of Commerce, Washington, D. C., as the place at which all master and reference gages and standards of measurements are to be certified. This is intended to include all such master and reference gages and standards of measurement as are used by the ———— for the work coming under the cognizance of the Bureau, both in manufacturing and inspecting.
>
> All master and reference gages and standards of measurement used by private manufacturers in carrying out contracts for the Bureau, where certification is called for by the contract, shall be certified by the Bureau of Standards.

As pointed out by Mr. Viall, this memorandum does not call for the certification of unimportant gages. Each bureau prepares its own contracts, and thus has complete control of the extent to which certification shall be required. The master gage, in the mind of the committee, is the one gage or set of gages used as the ultimate reference in a factory on a certain piece of work. The reference gages are the gages distributed throughout the plant with which the working gages are to be compared from time to time. The reference gages are subject to wear, relatively small but possibly appreciable, while the master gages are not subject to wear during the life of the contract. If every gage could go through the Bureau of Standards it would be desirable, but since this is not a physical possibility, the committee has included in its recommendation

only the master and reference gages. Regarding the objection that this method of certification divides the responsibility for the correctness of the finished product between the Government and the manufacturer, the committee does not regard the proposed plan as any sharing of responsibility whatever. The Government furnishes the standard and the manufacturer must work to it.

Meeting Opened to Discussion

The Chairman then declared the meeting open to all present, and called upon a number of those present to lead the discussion. Naval Constructor S. M. Henry heartily endorsed the proposals of the committee, and stated that they met the views of the Bureau of Construction and Repair.

Major L. A. Fischer, in charge of the Gage Design Section of the Ordnance Department, announced that the plan, practically as proposed, had been in operation for some time by the Ordnance Department on contracts for munitions which call for the manufacturer to supply inspection gages. The Government furnishes a set of master gages to the manufacturer and to the Government inspectors. These are kept at the factory and all inspection gages referred to them.

That there would be no delay in submitting gages to the Bureau of Standards, and had been none up to this time, was brought out by Major Fischer, who organized the gage-inspection service of the Bureau during the time when he was in charge of the division of Weights and Measures. Based on the experience of our allies, the gage-inspection division has been organized on generous lines.

Major Henry W. Torney, Inspection Department, Equipment Division, Signal Corps, said that his department had already made considerable use of the Bureau of Standards for gage certification, and expected to continue doing so.

Experiences of Our Allies

An international note was added to the meeting by the presence of a representative of the British Ministry of War in the United States, Mr. H. J. Bingham-Powell, Inspector of Gages and Standards, who emphasized the importance of advising gage makers in advance what they would have to meet in the inspection of their product, and the importance to gage makers of having facilities for knowing that their product is correct. He extended a cordial invitation to all present to inspect the facilities of the British Ministry for the certification of gages.

The experience of Canada was outlined by Capt. Richard J. Durley, of the Imperial Munitions Board. At one time the Canadian troops in France were being sorely pressed through lack of sufficient ammunition, and it was necessary to speed up the manufacture of a certain fuse. Upon studying the situation, it became evident that the date on which a supply of fuses could be obtained was entirely dependent upon the dates at which inspection gages could be had. This has been the case also on most other work. Every day which passes without a sufficient supply of inspection gages means another day on which there will be no product. The present practice in Canada and in Great Britain is to have all gages pass through the Imperial Munitions Board and the National Physical Laboratory, respectively, for certification. They are then given a serial number, issued to the inspectors, examined at intervals and when worn down to the permissible limit are returned, reëxamined and scrapped.

In reply to a question from Major A. W. Erdman, Inspection Division, Ordnance Department, as to the meaning of certification as used in the proposed clause, Major Fischer stated that this was understood to be the certification by the Bureau of Standards that the gage was within the tolerances permitted to the manufacturer of the gage by the bureau in charge of the work on which it is to be used. Verification, on the other hand, means that the size of the gage is determined regardless of whether this size is proper for the intended use of the gage or not.

An interesting point brought out by Major Erdman was whether, in view of the fact that there are not available enough highly skilled gage makers to furnish the very large quantities of gages, especially thread gages, now required, it would be advisable to utilize a large number of less skilled men. This would no doubt result in less accurate gages, but if within the limits allowed the manufacturer who is to use the gages in producing munitions, it would simply result in reducing his manufacturing tolerance without affecting the quality of the product. This might involve difficulties in some cases, but many manufacturers would be able to get into production quicker and a great increase in the output of gages would be possible.

Advantages to Manufacturers of New Plan

The advantage to manufacturers of gages of having their factory standards approved by the Bureau of Standards, or of having sub-stations at important points throughout the country, was brought out by Mr. Frank O. Hoagland, Assistant Works Manager of Pratt & Whitney. Where a gage maker has an order for a set of duplicate gages, subject to certification, he cannot make up more than one set until the first has been approved unless his standards have been approved. The first having been approved, it is readily possible to duplicate it and to check it. All purposes would therefore be served if only the first gage were sent to Washington for certification and the duplicates passed upon at a sub-station more accessible to the place of manufacture.

Then followed an exceedingly interesting discussion of numerous phases of the gage question, participated in by men of large experience on such matters with the Government, gage makers and munition manufacturers. Among the topics covered were the standardization of gages, the fixing of tolerances fair to the maker and user, means of securing greater production of gages and of regulating the flow of production, greater publicity in the technical press concerning the design, manufacture and use of gages, and other valuable suggestions now available for the use of the committee in the stenographic notes of the meeting. One hundred of America's leading men in this field freely contributed from their rich experience to the end that the industries of the country might make a prompt and satisfactory response to the call for enormous quantities of those mechanical products so essential to the successful prosecution of the war.

At the conclusion of the discussion, the contract clause and the accompanying memorandum prepared by the committee were approved by a unanimous vote of the meeting. The committee will now be able to present the matter in final form to the Government departments with the full approval of the two great engineering societies qualified to pass an authoritative opinion on this subject. There is every reason to believe that the suggestion will be promptly adopted and the committee will then be able to turn to other phases of its work.

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

PRESIDENT TAFT said that the engineer, equally with the physician, was essential to the winning of the war. The Council of this Society, together with the boards of management of the other societies and the representatives of the engineering colleges, have persuaded the Secretary of War to make similar provision for engineering students who may be drafted to the provision made for students in medicine and dentistry who may be drafted; namely, that the students under the draft be reassigned to their respective colleges, to complete their technical courses. This is most impressive.

With the recognition by the nation of the opportunity for service goes the responsibility of rendering that service. The loyalty of the members of the Society and of the profession in general has never been questioned. The only unsatisfactory feature has been the inability of a large proportion of our members to find the opportunity for expression. Whereas approximately ten per cent of the membership is now in the service, several times this number would gladly join if they were only permitted.

I am happy to report the splendid progress of the Engineering Council, and the spirit of coöperation which is being developed between the engineering societies and the committees which have been engaged in war work. There seems to be every prospect now of having a joint committee at some time in the very near future.

The conspicuous service which the Society has been rendering is in its Engineering Resources Committee, whereby the Government or any industry or individual can obtain the names, addresses, and accomplishments of specialists of every variety. These the Society has been able to furnish to such an extent that over fifteen hundred members have been suggested for important service. A corps of experienced assistants loaned by this Society has undertaken now the classification of members of other societies who are coöperating in the movement. This is an activity which all members of the profession may report with considerable pride.

Calvin W. Rice,
Secretary.

THE NEW OFFICERS OF THE SOCIETY

ALL the officers listed on the ballot prepared by the Nominating Committee appointed by the President and consisting of L. E. Strothman, *Chairman,* Willis H. Carrier, Frederick W. Gay, A. M. Lockett and Paul B. Morgan, were elected at the opening session of the 38th Annual Meeting on Tuesday evening, December 4, 1917. The elections were: President, Charles T. Main; Vice-Presidents, Spencer Miller, Max Toltz and John Hunter; Managers, Fred A. Geier, D. R. Yarnall and Fred N. Bushnell; Treasurer, William H. Wiley. A brief biographical note of each of the new officers is given below.

Charles Thomas Main

Charles Thomas Main was born in Marblehead, Mass., on February 16, 1856. He attended the public schools in that town and was graduated from the Massachusetts Institute of Technology with the degree of S.B. in the department of mechanical engineering.

He remained at the Institute as an assistant in the department of mechanical engineering for three years after graduation.

In the fall of 1879 he went to the Manchester Mills, Manchester, N. H., as draftsman. From there, on January 1, 1881, he went to Lawrence, Mass., as engineer for the Lower Pacific Mills. In March 1886 he was made assistant superintendent and in July 1887 superintendent of the mill, having in charge the engineering work also during the latter periods.

During this period of eleven years he had charge of the reorganization and the rebuilding of a large portion of the above-mentioned plant, and for something over five years had charge of its operation.

About this time Mr. Main decided that he preferred to follow engineering rather than administrative work and resigned his office at the Pacific Mills. After one year in Providence, R. I., spent in engineering and mill work, he formed an association with Mr. F. W. Dean and conducted a business under the name of Dean & Main, devoted largely in the early days to textile, mill work, but gradually broadening so as to include other industrial plants. This association existed from January 1893 to January 1907, when it was dissolved. Since that time he has conducted an engineering business under the name Chas. T. Main.

During the period from 1893 to the present time a large number of industrial plants have been designed and constructed under his direction and many others reorganized. The steam engineering for industrial plants developing into steam-power-plant work, and the water-power work into hydroelectric developments.

Among the largest undertakings in the industrial plants are the Wood Worsted and Ayer Mills in Lawrence, Mass., and in the hydroelectric work four developments for the Montana Power Company, aggregating about 280,000 hp.

He has acted as consulting engineer on many projects and as expert witness or referee in many important cases and has placed valuations on many industrial plants for various purposes.

He was elected to membership in The American Society of Mechanical Engineers in 1885 and has been a manager for three years. He is also a member of the American Society of Civil Engineers, the American Institute of Consulting Engineers, the Boston Society of Civil Engineers (past-president), and of other technical societies; is president of the Engineers' Club in Boston, and is serving his second term as term member of the Corporation of the Massachusetts Institute of Technology.

He has written several papers on engineering subjects, some of which have been presented at meetings of the Society.

Mr. Main has been interested for many years in public

affairs and has served in several municipal offices for the purpose of advancing the idea of good government and doing his share of public work.

Spencer Miller

Spencer Miller was born at Waukegan, Ill., April 25, 1859. He was graduated at the Worcester Polytechnic Institute in 1879, and after tutoring for a few months at Amherst College, entered the shops of the U. S. Wind Engine & Pump Co., of Batavia, Ill., where he remained for nearly a year. He then became a draftsman with the Link-Belt Machinery Co., Chicago, where he designed a number of rope drives, and a novel equipment for handling cargo by continuous systems of conveying for the Union Steamboat Company. He made important improvements in rope driving with grooved pulleys of different diameters by varying the angle of the grooves. This invention was the subject of a paper entitled A Problem in Continuous Rope Driving, presented by him before the American Society of Civil Engineers in 1897.

In 1886 he became associated with the Lidgerwood Manufacturing Co., of New York, which was then manufacturing a crude overhead cableway system involving fall-rope carriers of the chain-connected type, and he developed an entirely new fall-rope carrier system, which eventually resulted in obtaining a conveying speed of 2000 f.p.m. Mr. Miller continued the development of the cableway, added automatic dumping features so that loads could be dumped at the will of the engine operator, made towers self-propelling, traveling on tracks so that a great area could be covered, and adapted the cableways to the use of grab and scraper excavating buckets, so that today the cableways will convey single loads up to thirty tons over spans exceeding 2000 feet. The most noted installations were on the Panama Canal, where they were used for the construction of the locks. He developed the cableway as applied to the removal of logs from the swamp lands, reducing the cost of the logs at the mills 50 per cent, and adapted the log-skidding cableway for mountain work, skidding logs from the crests of the mountains, and out of gorges and ravines, enabling logs to be taken out of timberlands hitherto inaccessible by previous methods, one of the latest machines spanning 4200 feet.

Mr. Miller's latest adaptation of the cableway was on the Mississippi Levee Construction work. This machine is a straight-line cableway excavator, span 700 feet, operating a 3-yard drag scraper bucket.

One of the early problems of the Spanish-American War was presented to the Navy Department in the question of coaling ships at sea, and Mr. Miller designed a marine cableway that made it possible to transship coal under headway at sea. In coaling ships in harbor his method of broadside handling has increased the capacity from 25 to 150 tons per hour, and one man now does the work which under the old system required eighty. Many new colliers of the U. S. Navy, notably the *Jason*, *Orion* and *Neptune*, are equipped with this transfer system, for delivering coal to ships alongside in smooth water. In 1911 he made the refueling of warships at sea the subject of a paper read before the Society of Naval Architects and Marine Engineers. One of the most revolutionary devices invented by Mr. Miller is his breeches buoy cableway apparatus in use by the U. S. revenue cutter service, by which passengers can be rescued from any ship in the heaviest sea.

The greatest problem presented in these marine cableways was the maintenance of a constant tension in the supporting cable and also in the conveying cables, the surging of the ships tending to produce a variation of 600 per cent in the tension of the cables. Mr. Miller developed an engine which automatically maintained within 10 per cent a constant tension on these cables, compensating the varying strains produced by the wave motion affecting the ships. With this automatic-tension engine, Mr. Miller successfully solved the problem of bunkering fuel oil at sea, a supporting cable for the oil hose being held at constant tension by the engine.

His final development of this automatic-tension engine is for use as a towing engine. Its use eliminates the shock effect on the towing hawser and permits the use of lighter hawsers, of much shorter length, and limits the tension on the cable to a predetermined amount well within the safety limit of the cable, thus providing against excess strain.

In view of Mr. Miller's many activities in marine matters, it was natural that he was selected as a member of the U. S. Naval Consulting Board at its inception, and of which board he is now a member. He is chairman of The Fuel and Fuel Handling Committee, and also of the Life Saving Committee.

Aside from his engineering activities, Mr. Miller is greatly interested in civic and municipal improvement, especially in the establishment of public libraries, parks and playgrounds. He is a Vice-President of The American Society of Mechanical Engineers; member of the American Society of Civil Engineers, American Institute of Mining Engineers, Society of Naval Architects and Marine Engineers, and the Canadian Institute of Mining Engineers.

Max Toltz

Max Toltz was born in Coeslin, Germany, in 1857, and was graduated from the Royal Polytechnic College of Berlin in 1878. He came to the United States in 1882 and became associated with the St. Paul, Minneapolis & Manitoba Railway, now the Great Northern, serving successively as draftsman, assistant engineer, bridge engineer and mechanical engineer. In the latter capacity he had charge for four years of the motive-power department.

From 1903 to 1905 he acted as consulting engineer of the Canadian Pacific Railway, during which time he built the Angus Shops near Montreal and also those at Winnipeg. He also acted as consulting engineer for the Erie Railroad during this period. In 1905 he became vice-president and general manager of the Manistee and Grand Rapids Railway, acting also as consulting engineer for different railroads at the same time. Since 1908 he has conducted a private practice, including the work of consulting engineer for the Great Northern Railway, the Northern Pacific Railway, the Chicago, Milwaukee & St. Paul and the Butte & Anaconda railways, reporting especially upon the electrification of steam roads, and also specializing in power plants, grain elevators and large handling plants, and iron-ore docks.

From 1900 to 1913 he was Captain of the Engineer Corps, Minnesota National Guard, and since 1913 Major of the Engineer Corps. He is now engaged in camp construction for the Government, his first camp having been Camp Robinson at Sparta, Wis. He is now at Camp Dodge, Des Moines, Iowa, where he has charge of the installation of the heating of the entire camp.

John Hunter

John Hunter was born in Scotland in 1866, and was educated in public schools, serving his apprenticeship as a mechanical engineer before leaving Scotland.

The first twenty years of his career were spent in marine

service. In 1885 he joined the Red Star Line, *S. S. Westerland,* as junior engineer, sailing between Antwerp and New York, rising to first assistant of the *S. S. Friesland* of the same company in 1891. In 1895 he transferred to the new *S. S. St. Louis* of the American Line, running between New York and Southampton, as senior first assistant engineer, and at the outbreak of the Spanish-American War in 1898 was appointed chief engineer of the *S. S. St. Paul,* with the rank of Lieutenant, U. S. A.

The *St. Paul* was taken over by the United States Navy, equipped as an auxiliary cruiser and fitted out with twenty 5-inch guns, and under the command of Admiral Sigsbee saw much active service during the war which bore heavily on the crew. When the *St. Paul* went back in the North Atlantic service, Mr. Hunter continued as chief engineer until August 1905, when he gave up his naval career to enter consulting work.

During his twenty years of sea service he had traveled 1,500,000 sea miles, and had seen an interesting development in marine engineering. The steam pressure carried on boilers in his ships had risen from 10 to 200 lb., and the old low-pressure engines had given place first to the cross-compound type, with 80 lb. pressure, then to the triple-expansion three-cylinder engine with 165 lb., and finally to the six-cylinder quadruple expansion engines and twin screws of the *St. Paul,* with their 200 lb. pressure.

In August 1905 he went to St. Louis to take the position of chief engineer of the power plants of the Union Electric Light and Power Co. At that time the Ashley Street plant was under construction and changes were being made to increase the capacity of the station. In the early part of 1907 he was given charge of the construction work of the company and the completion of this plant, including the last section of the east river wall, where it was found necessary to sink two caissons to bed rock, 22 ft. below the zero stage of the river. He was also in charge of the steam-heating plant of the company.

He has recently been called into the service of the Government in the capacity of district manager for the Emergency Ship Building Corporation, with headquarters in New York City.

Mr. Hunter has been prominent in the affairs of national societies, having served for three years as a member of the Prime-Movers Committee of the National Electric Light Association. He served also as president of the Engineers' Club of St. Louis and for two years as president of the Caledonian Society.

Frederick August Geier

Frederick August Geier was born in Cincinnati, Ohio, on June 23, 1866, and at the usual age entered the public schools, wherein he continued his studies until graduated from Woodward High School with the class of 1884. Two years later he engaged in the banking business in Newton, Kansas, but returning to his native city in September 1887, became connected with The Cincinnati Milling Machine Company as bookkeeper. He now owns a controlling interest in, and is president of, this company, which is generally acknowledged to be the largest plant in the world devoted exclusively to the manufacture of milling machines and accessories.

Some years ago, when The Cincinnati Milling Machine Co.'s business had grown beyond the capacity of the old plant (located on Spring Grove Avenue), Mr. Geier conceived the idea of organizing a factory colony grouped about a central power plant. Three other companies joined at once in the project, and the outcome of the idea is the present factory colony at Oakley, a suburb of Cincinnati.

The C. M. M. Co. now has one of the most modern plants in existence and employs about 2000 people. It provides ideal factory conditions as to light, heat, ventilation, and sanitation, maintains an employees' service and medical department, and provides space and equipment for a cafeteria, which is operated for the employees by a committee chosen by themselves. It also recently started a coöperative store for the benefit of its employees.

Mr. Geier is also president of The Factory Colony Co., The Modern Foundry Co., and the Factory Power Co., is a director of The Cincinnati Rubber Mfg. Co. and The Cincinnati Bickford Tool Co., also a director of the Lincoln National Bank of Cincinnati and also the Central Trust Co., Cincinnati. He is a director of the Ohio Mechanics Institute. He is at the present time also president of the Council of Social Agencies of Cincinnati. He is a member of the board of managers of the National Society for the Promotion of Industrial Education. For five years he served as trustee of the University of Cincinnati and chairman of its board. He served two years as president of the National Machine Tool Builders' Association, and served as chairman of the Cincinnati Section of The American Society of Mechanical Engineers for the term 1916-1917.

D. Robert Yarnall

D. Robert Yarnall, member of the firm of Yarnall-Waring Co., and also vice-president and general manager of the Nelson Valve Co., Philadelphia, was born in Delaware County, Pennsylvania, in 1878. He was educated at the University of Pennsylvania, receiving the degree of Bachelor of Science in 1901, and that of Mechanical Engineer in 1905.

For a short time after graduation he was engaged in engineering work in connection with the design of cement plants, and for the five years just prior to 1906 he was superintendent of construction for Mr. Charles Edgerton, consulting engineer, Philadelphia. For the next four years his efforts were devoted to the interests of the Stokes & Smith Co., manufacturers of box-making machinery, during which time he assisted in installing the Taylor system of scientific management.

In 1910, Mr. Yarnall, with Mr. B. G. Waring, organized the Yarnall-Waring Co., manufacturers of power-plant devices, which company operates and manages the works of the Nelson Valve Co., of which Mr. Yarnall is also vice-president and general manager.

In 1911, Mr. Yarnall introduced into America the first V-notch weir meters for measuring rates of flow, and subsequently he invented a number of improvements on this device, including the now well-known heater-meter combination which is used extensively in power plants. He is the author of the paper entitled The V-Notch Weir Method of Measurement, presented before the Annual Meeting of the Society in 1912; and has just presented a paper before the Philadelphia Local Section, entitled Recent Developments in V-Notch Weir Measurement. He is also the inventor of a number of successful power-plant valves and other steam specialties.

He has taken an active part in the Engineers' Club of Philadelphia, being a member from April 18, 1903, and vice-president from February 1916 to date. During this period he was active in bringing about the broad plan of affiliation of the Engineers' Club with the local sections of national societies, the plan of affiliation now being familiarly referred to by other cities as the "Philadelphia Plan."

He entered the Society as a Junior in 1903, and was elected to full membership in 1911. Mr. Yarnall has been a member of the Society's Committee on Sections since its formation, and during the past year has been chairman of this committee.

He is a member of the Engineers' Club of Philadelphia, The University Club and The Franklin Institute.

Fred N. Bushnell

Fred N. Bushnell was born in Saybrook, Conn., in 1867. He received a high school education, and in 1883 moved to Providence, R. I., entering the works of the Providence Steam Engine Company, where he acquired his shop experience. His early education was supplemented by a special course of study in engineering subjects under private instruction, and he entered the drafting room of the Providence Steam Engine Company in 1885, where for several years he was engaged in designing engines, boilers, bolt-forging machines and other miscellaneous products of this company.

In 1889 he entered the employ of Robert Wetherill & Co., of Chester, Pa., returning to the Providence Steam Engine Company in 1890 as superintendent.

The mechanical equipment of many of the early electric power stations was built and installed under Mr. Bushnell's supervision. The rapid development of the electrical industry impressed Mr. Bushnell as offering unusual opportunities for young men with engineering training, and he decided to give up manufacturing and to devote his energies to electric-power-station work.

In 1893 he accepted a position as chief engineer of the Narragansett Electric Lighting Company, of Providence, R. I. In 1902 he was appointed chief engineer of the Rhode Island Company, which controlled the electric railways in Providence, Pawtucket and other towns in that vicinity.

He occupied these positions until 1907, when he entered the employ of the Stone & Webster Engineering Corporation of Boston, and was given charge of extensive power-station work for the Boston Elevated Railway Company. After this he was engaged for some time in making special investigations and reports on engineering projects, and in 1909 was appointed engineering manager of the Stone & Webster Engineering Corporation, in charge of all engineering work in its Boston office. In 1912 he was appointed vice-president and engineering manager.

Some of the recent works with which Mr. Bushnell has been identified are the alternating-current power system of the Boston Elevated Railway Company, comprising a large generating system, sub-stations and underground transmission; the power station of the Republic Railway & Light Company near Youngstown, Ohio, and the new River Station of the Buffalo General Electric Company, Buffalo, N. Y.

Mr. Bushnell became a member of the Society in 1891.

William H. Wiley

William H. Wiley was born on July 10, 1842, in New York City, and received his A. B. degree from the College of the City of New York in 1861, and the degree of C. E. from Rensselaer Polytechnic Institute in 1866. He also studied as a special student at the Columbia School of Mines in 1868.

At the outbreak of the Civil War, in 1861, he joined the 7th Regiment, New York State Militia. In March, 1862, he was enrolled as First Lieutenant in the Independent Battalion, New York State Volunteers, mustered into the service, and served under General McClellan. When the regiment was mustered out in 1864, he was given the title of Major, U. S. Volunteers, for services under General Gillmore, on Morris Island, S. C.

Since 1876 Major Wiley has been a publisher of scientific works. He served as a member of the 58th, 59th and 61st Congresses from New Jersey. In 1897 he was president of the International Jury of the Brussels Exposition, and was a member of the Superior Jury, Brussels. He was a commissioner from New Jersey at the St. Louis Exposition in 1904.

Major Wiley is the author of a book on Yosemite, Alaska and Yellowstone, published in 1888, and has acted as New York correspondent for London *Engineering*. He is a member of the American Society of Civil Engineers, the American Institute of Electrical Engineers, the American Institute of Mining Engineers, the American Association for the Advancement of Science, the National Geographic Society, the Order of Leopold, Belgium, and the Loyal Legion.

Major Wiley has been a member of the Society since its organization. He was appointed on the Finance Committee in 1882. While serving as Chairman of this Committee he was elected Treasurer of the Society, in 1884, and has been regularly nominated and elected for the period of thirty-three years which has since elapsed.

COUNCIL NOTES

NOVEMBER 16, 1917

A MEETING of the Council was held on the afternoon of Friday, November 16, 1917,[1] in the rooms of the Western Society of Engineers, Monadnock Block, Chicago. The following members were present: Ira N. Hollis, *President*, Max Toltz, A. M. Greene, Jr., D. S. Jacobus, Charles T. Main, W. F. M. Goss, John A. Stevens, C. H. Bierbaum, R. H. Fernald, William B. Jackson, F. R. Low, *Chairman of Publication Committee*, Charles Russ Richards, representing the *Sections Committee*, Alex. D. Bailey, Arthur L. Rice, George R. Brandon and Philip N. Engel, officers of the Chicago Section of the Society, attending the meeting by invitation, and Calvin W. Rice, *Secretary*.

[1] The November meeting took place after the December JOURNAL went to press.

The Council was welcomed by Mr. D. W. Roper, vice-president of the Western Society of Engineers.

Anglo-American Conference. It was voted to authorize the Executive Committee to accept the invitation of the Aircraft Production Board to the London conference, and to authorize the President to appoint a delegate.

A.S.M.E. Boiler Code. The Boiler Code Committee submitted a Revision of the Code which was received and ordered printed in THE JOURNAL. This was published in the December issue.

Gas-Power Committee. It was resolved that the existing committee be discharged, with thanks for their services, and a new Gas-Power Sub-Committee was appointed, as follows: C. H. Benjamin, *Chairman*, Harte Cooke, E. J. Kane, W. T. Magruder, H. R. Setz, H. F. Smith, J. H. Spitzglass, W. V. Stout, and D. McCall White.

Committee on Technical Schools. A committee of W. F. M. Goss, *Chairman*, A. M. Greene, Jr., and D. S. Jacobus was appointed to formulate for presentation to the Council at its next meeting a statement of the policy which in the opinion of the committee should be observed with reference to the maintenance of the activities of the technical schools as an agency for promoting efficiency in war.

Western Society of Engineers and Chicago Section. It was resolved that the Council extend a vote of thanks to the Western Society of Engineers for the use of their rooms and also to the Chicago Section for their hospitality.

Adjournment was taken to meet in New York on December 4, 1917, at the Annual Meeting.

December 4, 1917

At the meeting of the Council on December 4, 1917, preceding the 38th Annual Meeting, the following members were present: President Ira N. Hollis presiding, John H. Barr, C. H. Benjamin, R. M. Dixon, *Chairman of Finance Committee*, R. H. Fernald, W. F. M. Goss, Arthur M. Greene, Jr., W. B. Jackson, D. S. Jacobus, Julian Kennedy, F. R. Low, *Chairman of Publication Committee*, C. T. Main, Spencer Miller, H. de B. Parsons, C. T. Plunkett, Max Toltz, William H. Wiley, *Treasurer*, Past-Presidents John A. Brashear, James Hartness, Robert W. Hunt, F. R. Hutton, Jesse M. Smith, Ambrose Swasey, Worcester R. Warner, S. T. Wellman, by invitation, Dr. C. R. Mann, of the Carnegie Foundation, and Professor Gardner C. Anthony, of Tufts College, and Calvin W. Rice, *Secretary*.

Coal Conservation. President Hollis gave a resume of the matters leading to the request from Fuel Administrator Garfield for coöperation in the matter of coal conservation, and announced that the following appointments had been made: As consulting engineers to the Bureau of Mines, Charles L. Edgar, L. P. Breckenridge, R. H. Fernald, and Charles Russ Richards; for the U. S. Chamber of Commerce Fuel Committee, the request being made that Dr. Ira N. Hollis, President, serve as one of the members, the President appointed in addition: J. W. Lieb, L. P. Breckenridge and F. H. Clark.

Aircraft Standardization. In response to the invitation from the Aircraft Standardization Board, James Hartness, Past-President, was appointed the representative of the Society to the joint conference shortly to be called in London on the matter of standardization of aircraft production.

Boiler Code Interpretations. Interpretations covering Cases Nos. 177-180 were approved with slight changes and ordered published in The Journal.

The Council expressed its appreciation of the magnificent offer of Dr. Brashear to secure for the Library the works of Professor Langley, and ordered this offer communicated to the Library Board for appropriate action.

The thanks of the Council were returned to the retiring President, Dr. Hollis, for his uniform courtesy and untiring interest and efficient direction of the work of the Society during the past year.

Adjournment was taken to meet on Friday, December 7, as the Council for the year 1918.

December 7, 1917

The first meeting of the Council for the year 1917-18 was held Friday, December 7, on adjournment of the Annual Meeting. There were present C. H. Benjamin, A. M. Greene, Jr., F. A. Geier, W. F. M. Goss, John Hunter, R. H. Fernald, Ira N. Hollis, F. R. Hutton, W. B. Jackson, D. S. Jacobus, C. T. Main, *President*, H. de B. Parsons, D. R. Yarnall, Wm. H. Wiley, *Treasurer*, by invitation, H. A. Harris, Chairman of the Gage Committee, and Calvin W. Rice, *Secretary*.

The Technical Schools in War. Dr. W. F. M. Goss, Chairman, presented a revised report of his committee on the subject of technical schools in the war, and resolutions passed by the Engineering Council and the Society for the Promotion of Engineering Education were also read.

It was then voted that:

1. The Council of The American Society of Mechanical Engineers recognizes the serious responsibility of the engineer in the prosecution of the war, not only in the corps of engineers, but in the many other branches of the national service where highly trained engineers are required. It urges the importance, as a war measure, of utilizing to the fullest the present engineering ability, and of maintaining unimpaired the engineering strength of the nation for the successful prosecution of military operations, and for the support of the sustaining industries.

2. To this end the Council of The American Society of Mechanical Engineers points out the necessity for establishing an agency for coördinating the military needs for technically trained men, the available supply of such men, and the sources of training. It urges that schools of engineering as the principal sources of this training be regarded as closely allied in the national purpose with the Military and Naval Schools of the nation, and that in the further administration of the draft the attitude of the Government toward them be such as to maintain the efficiency of these schools.

3. The plea for attention which is herein urged is not made in the interest of schools or of students, but is made solely for the full utilization of existing engineering resources and the preservation of a source of supply of engineers.

It was resolved that copies of these resolutions be sent to the Secretary of War and to the Provost Marshal General, that the Council earnestly support and approve the resolutions of December 6, passed by the Engineering Council, and that such endorsement be included in the communication sent to the Secretary of War and to the Provost Marshal General.

Sections. On recommendation of the Committee on Sections, it was voted to approve the following appointments on local committees:

Cincinnati: George Galbraith, *Chairman*, Henry Ritter, *Vice-Chairman*, J. T. Faig, *Secretary*, E. A. Muller and A. J. Baker.

Connecticut: C. K. Decherd, *Secretary-Treasurer*.

Buffalo: F. E. Cardullo, *Chairman*, W. A. James, *Vice-Chairman*, E. B. Neil, *Secretary*, J. W. Gibney, *Treasurer*.

Student Branches. On the recommendation of the Committee on Student Branches, it was voted to approve the establishment of a Student Branch at Tufts College.

Dues of Men in Military Service. It was voted that the procedure under B 16 (*b*), suspending the dues of members in active service, be as follows: In each case the Secretary shall require a written application from the member or a request in person or by representative, stating the facts of his service. Second, the Secretary shall refer each application to the Membership Committee with a request that the Committee report to the Council, after considering the facts in each case, the names of those members whose dues, in the opinion of the Committee, should be remitted.

Power Test Committee. In response to the request of the members attending the public hearing on the Power Test Codes at the Annual Meeting, the President appointed three members of the Society as its representatives on a Sub-Committee on Water Wheel Code, to act in conference with the appointees from the National Electric Light Association, the

American Institute of Electrical Engineers, and the American Society of Civil Engineers.

Boiler Code Committee. E. R. Fish and F. R. Low were appointed on the Committee.

Further Appointments. It was voted that Ambrose Swasey be appointed to succeed himself for a term of four years as a representative on the Board of Award of the John Fritz Medal.

W. F. M. Goss was appointed to succeed himself for a term of one year as the representative appointed by this Council to the Engineering Foundation Board.

R. M. Dixon was elected Trustee of the United Engineering Society to serve for a term of three years, to fill the vacancy caused by the expiration of the term for which John R. Freeman was elected.

Charles Whiting Baker was appointed to succeed himself for a term of three years to represent the Society on the Engineering Council.

George J. Foran was also appointed to represent the Society on the Engineering Council to fill the unexpired term of John H. Barr, who asked that his resignation be accepted due to the demands of Government work in which he is engaged.

Executive Committee. Chas T. Main, *Chairman,* Ira N. Hollis, D. S. Jacobus, Arthur M. Greene, Jr., Spencer Miller and John Hunter were appointed an Executive Committee of the Council under the provisions of B 26.

Adjournment was taken to meet in New York on Friday, January 18, 1918.

Calvin W. Rice,
Secretary.

WELCOME TO CIVIL ENGINEERS

In the Auditorium of the Engineering Societies Building on the evening of Friday, December 7, the American Institute of Mining Engineers, The American Society of Mechanical Engineers and the American Institute of Electrical Engineers, the three original Founder Societies, joined in a formal welcome to the American Society of Civil Engineers, the fourth Founder Society, which has recently removed from its former home on 57th Street, New York, to new quarters in the Engineering Societies Building.

Mr. Charles F. Rand, President of the United Engineering Society, presided. He said that the coming of the Civil Engineers rounded out a plan made by wise men some fifteen years ago. The association of the four national engineering societies was born of a very general desire to secure the full advantages which come from complete coöperation. These advantages had been realized in many previous examples, such as the John Fritz Medal Board of Award, the Engineering Foundation, the backing furnished by the four societies for the International Engineering Congress and the Joint Committee of Engineering Societies which preceded the Engineering Council.

He said the societies' obligation to Mr. Andrew Carnegie for his gift of over one million dollars used in the construction of the Engineering Societies Building should never be forgotten. He sometimes thought that the signing of a check for that sum may not have been very difficult for Mr. Carnegie, but he was able to certify that the provision of the remaining amount, through the efforts of the Founder Societies and their members, was surrounded by some difficulty, although now fully accomplished. The property of the Founder Societies, including the real estate, the Library, the reserve and endowment funds, exceeding two and one-quarter million dollars, all free and clear.

He referred to the administration of the United Engineering Society, which occupies the unique position of standing not over but under the Founder Societies, having been formed by them to perform certain specific acts governed by contracts. The Engineering Foundation, which has an endowment fund for research, the Engineering Council and the great Library under the care of the Library Board, are all administered as departments of the United Engineering Society.

If the administration of the United Engineering Society has been satisfactory it is because its officers have followed the footsteps of a former leader who shaped its policies and guided the Society for a number of years. He referred to Mr. Gano Dunn.

Welcome of Electrical Engineers

Mr. Gano Dunn, selected to express the welcome of the youngest Founder Society, the American Institute of Electrical Engineers, to the oldest, the original engineers, said that his welcome was all the more agreeable because it was made in a moment of enthusiasm and in the inspiring presence of all the other societies.

He thought that the occasion would mark the most eventful day so far in the history of the engineering profession in America, for on it had come to all the accession of the American Society of Civil Engineers, with its prestige and leadership. We in turn, under the influence of that prestige and leadership, should ourselves contribute to the joint result each day more and greater things, so that from now on the dream of those in all the societies that have seen in the days ahead a great and united engineering profession, would come one step nearer realization.

Welcome of Mechanical Engineers

Dr. Ira N. Hollis, speaking for The American Society of Mechanical Engineers, said that the union of the Founder Societies had come at a time when every man's and every woman's heart is moved at the danger before our country. We could be nothing else but brothers whether we were together in this building or not; but we are now thrown so much nearer together that we can make ourselves more effective in the service of our country by being under the same roof.

He emphasized the responsibility of the engineer for the industrial order of the twentieth century, and pointed out that it is his task to help make the world safe for democracy even as his instrumentalities are now adding to the horror of the great war.

He welcomed the Civil Engineers as brothers and as companions in the work that we shall jointly give our country.

Welcome of Mining Engineers

Dr. Rossiter W. Raymond, representing the American Institute of Mining Engineers, said that it was with personal as well as with representative pleasure that he, in the name of the American Institute of Mining Engineers, resigned the title of senior of the Founder Societies to the great and famous organization of the American Society of Civil Engineers.

Dr. Raymond spoke in his happiest vein and showed how the Civil Engineers, plus the Mechanical Engineers, plus the Electrical Engineers, made the Mining Engineers, and the work of the Mining Engineers gave to each of the other branches its greatest opportunity for displaying its capacity.

Mr. William L. Saunders, Past-President of the American Institute of Mining Engineers, speaking "at large," as the Chairman put it, expressed the view that the occasion celebrated not merely a physical union but a spiritual uniting of forces for participation in civic affairs.

Replies on Behalf of Civil Engineers

Mr. George H. Pegram, President of the American Society of Civil Engineers, responded on behalf of the new tenants. He averred that the Society moved to the joint house because service to our fellow-men, the interests of engineers and of the membership demanded it. The public, in his opinion, had not been informed on the work of the engineer, and not until it is so informed can engineers expect the recognition they deserve. In the closer coöperation of the four great societies he saw an opportunity for placing the engineer rightly before the public.

Dr. George F. Swain responded to the addresses of welcome on behalf of the members of the American Society of Civil Engineers resident outside of New York. It was his opinion that the society should have been in the union house before, and that it was there now in order that it might pull together with the other societies. In his opinion engineering organizations had heretofore confined themselves to two of four important purposes that they should forward. They had tried to advance engineering knowledge and to erect high standards for professional work and conduct. There remained now the work of making the engineer felt as a member of the community, and of working out plans by which the societies should do more for the individual member.

Annual Meeting Smoker

The Smoker of The American Society of Mechanical Engineers, held on the evening of December 5, attempted a radical departure from the two held at previous annual meetings. It was felt necessary to plan for 800, and to provide for the maximum sociability and intercourse it was decided to dispense with chairs. Arrangements had been made for an illustrated talk on Japan by Past-President John R. Freeman, who in the year had visited that country, together with Past-Presidents Brashear and Swasey, and the Auditorium of the Engineering Societies Building was secured for this feature. This allowed for assembling the members and guests before conducting them to the assembly rooms on the fifth floor. The features of the latter part of the smoker, when the participants were required to remain on their feet, were unfurling of a service flag showing the then 433 of the membership in active service for the Government, an auction of eight posters of past-presidents, the secretary, the honorary secretary and the treasurer, and the serving of refreshments. A combination march and snake dance was provided for getting the 750 or more who participated from the auditorium to the fifth floor, and as members and guests filed into the fifth floor rooms they were given a special box containing cigars and cigarettes and a card inviting contributions for smokes for the engineer regiments abroad. Altogether, including the money obtained from auctioning the posters, $313.86 was raised for this purpose. The idea of providing a maximum opportunity for mixing by omitting the chairs appears to have been eminently successful.

W. W. Macon.

Annual Meeting Excursions

Although conditions due to the war badly handicapped the Excursion Committee this year in arranging trips for the visiting members and guests at the Annual Meeting, yet four delightful trips were taken.

On Wednesday afternoon, December 5, a small party visited the Montgomery Ward Company's mail-order plant in Brooklyn and found much of interest there.

On Thursday afternoon a party of ladies took a sightseeing trip through downtown New York. Another party visited the Samuel L. Moore's Sons Corporation shipbuilding plant at Elizabethport, N. J.; this plant has been rebuilt and enlarged to take care of the increased demand for shipping and had ships in various stages of completion on the ways.

On Friday afternoon the Society was loaned the boat *Correction* by the New York Department of Correction for a trip around Manhattan Island. This trip was participated in by about 100 members and guests and was a most enjoyable occasion. Mr. Colwell's first-hand account of the trip is appended.

John H. Norris,
Chairman Excursion Committee.

BOAT EXCURSION

An exceptional excursion around Manhattan Island and through the bridges was provided for the members and their guests at the Annual Meeting. As some of the party expressed it, the trip "showed New York by daylight, twilight and dark."

Through the courtesy of the Department of Correction of the City of New York, a large and comfortable boat was at the disposal of the Society for this interesting and well-attended trip. A congenial party, including quite a few college men and a bounteous supply of lunch, left the city dock, East 26th Street, about 1:30 p.m. The day was ideal.

After passing under all the bridges, fifteen in number, during daylight, the Hudson River was reached under a full red setting sun, a little larger and brighter than Dr. Brashear's; but the Doctor's was a close second.

The good boat *Correction*, with Captain Parkerson in command, steamed up the East River, passing under the Queensborough Bridge and through Hell Gate Rapids, and approached the new bridge and viaduct of the New York Connecting Railway slowly so that all had a fine view of that magnificent and massive engineering masterpiece. The Captain turned the boat around directly under the bridge which gave an opportunity to see the steel span directly overhead, then proceeded south and went through the upper part of Hell Gate, to the west arm, and was shortly blowing four long blasts for the Harlem River Bridge to open. The city flag, blue, white and yellow, at the bow of the *Correction*, was like a magic wand as the drawbridges, eleven in number, were swung open in turn—Washington Bridge and High Bridge allow clearance and were not opened.

At High Bridge, which is one of the most artistic bridges in the world, the tide was running strong and Captain Parkerson did some nice maneuvering to take his boat between the piers that support the arches, there being very little clearance.

Many points of interest were passed including Blackwell's, Ward's and Randall's Islands where many city institutions are located. Many large power and large manufacturing plants, the Speedway used exclusively for trotting horses, New York University with the imposing Hall of Fame and Library located on a prominent elevation, were all passed in turn. There were some shipyards "doing their bit," and last but not least the Ship Canal, which required skill to navigate a large boat like the *Correction* on account of the strong current and the crooked and narrow channel.

Going south on the Hudson River, the old familiar points were in view—Riverside Drive, Trinity Cemetery, 129th Street Viaduct, Grant's Tomb, the Soldiers' and Sailors' Monument as well as the Palisades and the large manufacturing plants on the Jersey shore, also some of our own and the Allies' grim fighters and cruisers in the river looking real business-like.

James V. V. Colwell.

AMONG THE LOCAL SECTIONS

FOLLOWING the Business Meeting of the Society on Thursday morning, December 6, of the 38th Annual Meeting, there was held in the Auditorium of the Engineering Societies Building a "Sections Session," presided over by Mr. D. Robert Yarnall, Chairman of the Committee on Sections, and devoted to three-minute reports by those delegates from the Sections present. The reports, which are here published, were preceded by a statement from Mr. Yarnall of the accomplishments and aspirations of the Committee on Sections. As each delegate was making his report, a slide was thrown on the screen giving the history of the growth of his Section. Delegates were in attendance from Atlanta, Baltimore, Birmingham, Boston, Buffalo, Chicago, Cincinnati, Connecticut, Erie, Indianapolis, Milwaukee, Minnesota, New Orleans, New York, Philadelphia, Providence, St. Louis, San Francisco and Worcester.

Foreword by Mr. Yarnall

FOUR signal events this year will go down in this history of the Sections as marked developments in this activity. First, the new By-Laws, after two years' study by the Committee as to the requirements of the Sections and with due regard for the suggestions and comments made at the Sections Conference in 1916, were approved by the Council and are now in effect. The By-Laws were developed with the idea of granting all possible autonomy to individual Sections, and hence merely supply a skeleton on which to build Section activities. These By-Laws were printed in The Journal in November 1916, and have been distributed to the Sections' officers as well.

Second, a session of the Annual Meeting was for the first time this year given over to the discussion of Sections problems, thus recognizing the prominent place the Sections movement has in Society affairs. Delegates to this meeting were officially appointed by the Sections and the expense to the meeting paid by the Society.

Third, a most important development of the year has been the establishment of the first State Section—the Connecticut Section, with its five Branches at Bridgeport, Hartford, Meriden, New Haven and Waterbury. The president of the Connecticut Section, Mr. H. B. Sargent, will report further concerning this interesting development. Our Sections Committee would insert here a word of caution that we do not encourage the formation of other State Sections until this new plan has been thoroughly tried out.

Fourth, is the innovation of holding meetings of the Committee on Sections in the various cities where Sections have been established. During the autumn, members of the committee have visited in turn Bridgeport, St. Louis, Milwaukee, Chicago, Detroit and Philadelphia. All of the members of the committee have been present at these meetings with the exception of Mr. E. H. Whitlock who is now a major in the Engineer Officers' Reserve Corps.

Sections' Work Manifold in Phases

The phases of the Sections' work are manifold. In each center in which Sections are established opportunities for service arise at every turn. The new Sections' By-Laws govern the activities of each Section only to the extent of insuring that its procedure is in conformity with the Constitution of the Society; they leave the Section free to carry out the details of its coöperative work with other societies' sections and with the local engineering organizations and the public.

In addition to the short three-minute reports that will be given today, at this Sections' Session, delegates have come into personal contact with the Council and have thus had an opportunity to familiarize themselves with the parent Society's attitude towards its Sections. At both the Annual and Spring Meetings this year, as for the past few years, the Section delegates lunched with the Council and Past-Presidents, thus affording an opportunity for the officers of the Society to become acquainted first-hand with the spirit of the Section movement. These luncheons also afford an opportunity for the new officers representing Local Sections to become acquainted with the friendly attitude of the Council towards this important movement.

In order that this session may give all present an opportunity to carry away an idea of what has been accomplished by the Sections Committee during the past year, we will summarize briefly its activities, as some of these matters will not come within the scope of the very interesting reports which will be made by those present on "the firing line."

Progress by Sections' Committee

Since the last Annual Meeting the Committee has held nine meetings to discuss the manifold problems which have confronted the twenty-two Sections. In addition there have been a number of meetings of the Sub-Committee on By-Laws for Sections, this work being largely performed by Messrs. Marburg and Rautenstrauch, who are entitled to much credit for the painstaking effort they have devoted to it.

During the year the establishment of the following Sections has been approved: Baltimore, Erie, Connecticut and Ontario, Canada. The latter is the first Section to be established outside the domain of the United States; its headquarters are at Toronto, and its territory embraces the larger portion of the Province of Ontario, from which it takes its name.

We have prepared a few charts (exhibiting slides here) to illustrate certain phases of Sections development. The first of these shows that meetings of the Society are already fairly well distributed over the country, and I might add that during the last year over 150 meetings have been held by these Sections. At practically every one of these points the A.S.M.E. Section coöperates closely with the local engineering society or club. It is felt that this spirit of coöperation in these localities is one of the strongest elements for good work for which the Sections are responsible and it is not improbable that through it the much-prophesied combination of the national engineering societies may be effected. But of course the last thought does not come within the scope of the Sections' work. We do, however, wish to urge all Sections to cultivate the fine spirit of coöperation which is already manifest at so many points.

In the last few years there has been a wonderful increase in the number of those enrolled as members of the Society. Whereas the Committee on Sections does not hold that it is responsible for this growth, it is noticeable that the Sections movement was started just two years prior to the upward trend of the membership curve. There is no doubt that widespread holding of meetings throughout the country will encourage those at distant points to come into the ranks.

Sections and The Journal

The Sections Committee is desirous of having the Sections contribute their share to the upbuilding of The Journal through the development of high-grade papers and also to accept their share of responsibility for the much-needed development of research work as was discussed fully at the Sections Conference on Tuesday afternoon. With this aim it has recommended that the individual Sections appoint committees on papers and research. It is felt that a wealth of information is lying dormant and that this may be made available through two good live committees in each Section.

Thus far the Sections have not responded to these suggestions with as much alacrity as had been hoped. The fact that the British Government has recently appropriated fifteen million dollars for research work at a time when the very existence of the country is at stake shows how keen is the need for such work.

In this connection it is interesting to note that at two recent Sections' meetings the importance of industrial research has been emphasized; On October 18, at Cincinnati, Mr. F. O. Clements gave an interesting address on The Research Laboratory Applied to Industry, and again at Buffalo, on October 17, Doctor C. E. K. Mees, head of a well-known research laboratory, delivered a lecture before the Section on Scientific Research.

Other Good Suggestions

Another suggestion for Section activities is the opportunity offered to the Sections through the valuable group of papers presented yesterday at the Keynote Session. We might assign one of these subjects to each of the two or three Sections in whose localities the respective operations are being carried on, i. e., take the shipbuilding problem for instance, the Sections at San Francisco, Boston and Philadelphia might make it the subject of a symposium on shipbuilding, somewhat similar to the symposium on forging suggested by Mr. White of Milwaukee on Tuesday. By proper apportionment of the list we believe the Sections might contribute real aid to our country at the present time.

Each Section executive committee should consider the possibilities for increasing the membership of the Society during the coming year. We suggest that Chicago, for instance, which has about 417 members, might reasonably aim to add 100 new members, or make an increase of about twenty-five per cent. Some Sections might even be more ambitious, but there is no doubt that such an activity could be conducted upon lines so dignified as to leave no question concerning the high standard of membership which at present exists. That the time is opportune for such an activity is evidenced by the fact that over 1700 applications for membership in the Society have been received since January 1, 1917. The mechanical engineer is the engineer of the industries, and the industries are doing their share in making the world safe for democracy.

President Hollis, during his term of office, has visited practically every Section of the Society and has done much to create enthusiasm for the Section movement all along the line. Our Committee feels under great obligation to him for his constructive suggestions and his timely counsel. In our journeys among the Sections we have felt the impress of the ideals of professional and national service, and engineering democracy, which he has driven home. We are very glad to have him with us today to tell you personally of his conception of our Sections and the opportunities which are theirs.

Reports by Delegates

Mr. Poole (Atlanta): The influence of the Atlanta Section has accomplished a unique result. It has brought about the actual, practical recognition of engineering in municipal affairs. Of course, we know that all cities have their city engineering or equivalent departments. We also know that the city engineer or equivalent official is elected by popular vote, and therefore his department is honeycombed with politics, and that was true in Atlanta as elsewhere, but in Atlanta the influence of the Local Section of the A.S.M.E. has brought about the appointment of a non-political body known as the Board of Consulting Engineers for the City, composed of two civil engineers, one of whom is also a mechanical engineer, an electrical engineer, an architect, and a mechanical engineer pure and simple. The functions of this Board are purely advisory, but it has done some very unusual things. Disagreements between heads of the different departments on engineering matters, and on other outside interests, like the street railways, are all referred to the Board and its decision is final. That is an accomplishment we may be proud of.

Atlanta has also, due to the influence of the Local Section of the A.S.M.E., a mechanical-engineering department. I do not know of any other city in the United States which has that. The Department is non-political, the head of the Department is appointed by a non-political board, the members of which are prominent business men not connected with any of the big companies, but with engineering interests generally.

The Committee on papers has been promised three or four fairly good papers for the coming winter. Recently our Section has increased its membership from 30 to 35 per cent.

Mr. Varney (Baltimore): The members of the Baltimore Section are affiliated with the Engineers' Club. Some forty are now in active service.

We have had one meeting this season. We generally endeavor to have at our meetings one technical paper and one popular talk, so as to make the latter interesting to our visitors. In the notices sent to the affiliated engineers in our Section, we enclose a printed card setting forth the objects of the Section, and stating why they should contribute papers and attend in person, and the assistance they could give by their presence and their advice to the younger men coming in. If we had a number of such cards we could follow up by a telephone call and a personal visit that would add greatly to the effectiveness of our work. We have difficulty in getting our members out. New industries are being rapidly established in the suburbs around the water front, and we are not acquainted with the engineers connected with these enterprises. It is necessary at first to send them an invitation to attend our meetings, and a typewritten letter, signed personally by the Chairman, is sent to these engineers. I think our Sections Committee should furnish letters of this kind. The officers of the Section have limited facilities for getting around to widely scattered plants.

A large percentage of our members are at Annapolis.

Mr. Klinck (Birmingham): The Birmingham Section took a very active part in the formation of the Alabama Technical Association, the membership of which is only open to members of national societies. It is our intention at an early date to have a joint meeting under the auspices of the A.S.M.E., covering the conservation question, particularly of fuel, etc.

The Committee on Papers has a definite promise of three papers, with favorable prospects of securing more.

We endeavor to increase our membership entirely by personally discussing the matter with those whom we think should be with us, by inviting them to the meetings and getting them interested, and the results we are obtaining indicate that this is the right procedure for our territory. In addition, at our last meeting each member present pledged himself to get at least one new member during the coming year.

Our aim in getting members is to secure those whose membership will be active and permanent. We have from thirty to forty per cent of our membership at the meetings.

Mr. Starkweather (Boston): The aim of the Boston Committee is: First, to make the Section meetings of maximum engineering interest and value to the local members; second, to promote acquaintance and mutual regard among them; third, to

safeguard the Society from commercialism and to prevent control by any interest or group of interests, and fourth, to have in constant training a considerable number of sub-committeemen, so that there shall be true succession in office of able men well fitted for the duties involved.

For carrying out these four aims we have endeavored to make the meetings successful by having addresses on the vital questions of the present times, given by men eminent in their lines and with direct recent experience. The engineering features of the great war are legitimate questions of this kind, and for our first meeting this year on Trench Fighting and Modern Land Warfare we were fortunate enough to secure Lieut. André Morize, of the French Army, detailed for instructing the Harvard Regiment. At this event, the French and American colors were displayed, and the guests were prominent army officers. The meeting was preceded by a buffet supper and from 175 to 200 were present.

For the second meeting on Aeroplane and Air Fighting, the same general plan was followed with Lieutenant-Colonel Rees, of the British Royal Flying Corps, for the speaker. We used the British and American colors in this case, and made an effort to give some formality to the affair. There were probably 225 present.

The third meeting on Shipbuilding was even more successful than the preceding two from a technical standpoint. Mr. E. H. Ewertz, General Superintendent of the new Destroyer plant now nearing completion at Squantum, near Boston, and Mr. H. G. Smith, Vice-President and General Manager of the Fore River Shipbuilding Company, made addresses which were enjoyable and instructive. President Hollis presided, and we were further honored by having President-elect Main as our guest.

In all of these meetings some effort has been made to plan in advance for the discussion, but usually there is no lack of it, the subjects being of special interest to every one. Usually we begin at 7.30 and adjourn before 10.30, the luncheon or dinner being at 6.15.

To meet the requirement for the extension of acquaintance, we have reached the conclusion that if members and guests on meeting nights come direct to dinner from their offices and plants, much time is saved, their attendance is secured, and the hour or two so spent promotes the object sought. We are endeavoring to cultivate more cordiality at these lunches and dinners, so that by the time cigars are lighted every one has been repaid for coming and all are ready for the meeting. Because the Section really stands for the Society to ninety-five per cent of the members, everything possible should be done to emphasize and strengthen its influence and activities, and the social side should not be neglected.

Coming now to the delicate question of internal politics, our belief is that the greatest good to the greatest number should be the aim, and even further than this, that the Society has a positive function to perform (but not a mission) in maintaining the strictest standards possible of the ethics of engineering, untainted by commercialism. As this is a direct reflex usually of the personality of each Executive Committee, we desire as representative and broad-gage members as can be secured. In these days of large readjustments and shifting of capital and labor, nationalizing of industries, mobilizing of effort, saving of resources, etc., the Society has the opportunity of its existence, if it will but seize it, and each Section must take advantage of its local opportunities.

The appointment of three sub-committees of three members each on Papers, Sociability and Membership, and Research gives nine men who assist the Executive Committee, and who are possible nominees for the ensuing year. In this way we avoid carrying over old members of the Executive Committee. All the sections should be run with the same system and careful planning as any business, avoiding one-man rule, and with an eye solely to the enlargement of the usefulness of the Society to the community and to its members. We make it a point to encourage suggestions and criticisms, and in every way to enlist coöperation, and these three sub-committees are in line with this intent. We also provide combination meetings with other societies, and have an annual banquet.

In conclusion, while we do not claim the solution of all the problems which have tried the skill and patience of our predecessors, we believe their experience has been of value by indicating, at last, various things to avoid, and we shall endeavor to hand over to our successors a Section somewhat improved because of our connection with it.

MR. CARDULLO (Buffalo): Some five or six years ago the Local Section of the A. S. M. E. in Buffalo got together and started the Buffalo Engineering Society. The Society has a membership of several hundred and is increasing very rapidly. It holds a meeting every week. The Local Sections of the various engineering societies are affiliated with it, and our activities are carried out through the medium of the Buffalo Engineering Society, each local section being responsible for certain meetings of the Society. The A. S. M. E. Section is responsible for four meetings a year and the other local sections for a similar number.

I find that the greatest difficulty in the work of our Local Section of the A. S. M. E. is in the fact that the Section shows a disposition to elect as officers the busy managers of the biggest corporations in Buffalo, and in this way the younger men are rather left out of the game, and I think we are missing a good deal from the fact that we have not put the younger fellows into the places where they can bear the burden of the day.

The Buffalo Engineering Society is doing more for us than we are doing for ourselves, but in a way we feel that we are responsible for that, and as loyal and earnest members of the Buffalo Engineering Society we are doing a great deal for the community.

MR. ENGLE (Chicago): We held four general meetings, as usual, in 1917. They were informal, and were attended by from 100 to 180.

Recently we have taken up the matter of coöperating with the Western Society of Engineers.

MR. LANGEN (Cincinnati): We are affiliated with the electrical engineers and also the civil engineers, and we jointly elect a chairman, this officer usually changing about between the electrical and mechanical engineers each year. We aim to have eight good interesting papers each year. We have done this for the last two years, and the attendance of the meetings has increased considerably. The Chairman and Executive Committee of the Board meet once a week for a luncheon. We have no Papers Committee as the Chairman and Secretary of the Section take care of this. We invite the older students of the University of Cincinnati to hear specially interesting papers. Our membership is increasing and we have enough applications to increase it to from 111 to 150 this year. Twelve of our men have gone into the army in the last sixty days.

MR. SARGENT (Connecticut): The Connecticut Section is so young it has not much of a record back of it, except the record of the New Haven Section, now classed as the New Haven Branch of the Connecticut Section. The Section as organized consists of branches in Bridgeport, Hartford, Meriden, New Haven and Waterbury. It has held only one formal meeting.

We have been very generous, as we think we should be, in inviting those who are interested to come in, whether they are members or not, and some of them become members or applicants for membership in the Society.

The organization of the Connecticut Section began with an endeavor on the part of the engineers in Meriden to have a little social intercourse and get acquainted, and that acquaintance ripened into a belief that the members ought to have some recognition on the part of the Society. We met and devised a skeleton plan which the Committee on Sections approved, and that resulted in a kind of automatic organization, whereby, there being five proposed branches, the several Chairmen of these Branches should constitute the Executive Committee of the Section, and under that scheme we are now running.

We met under the auspices of the New Haven Branch at our last meeting. We will hold other meetings in different parts of the State, either in New Haven, Hartford, Bridgeport, Waterbury or Meriden, and the meeting will then be under the auspices of that Branch. We are trying to work out our organization to make it a sort of home-rule government within certain limits.

MR. SHERWOOD (Erie): I want to speak first about having notices issued by the Sections sent to the Chairmen and Secretaries of other Sections, so that we may see what means are taken to induce the men to come to the Sections meetings in the

various parts of the country. I have so far received no notice of meetings by other Sections, and I am frank to say that I have deferred putting the names of other chairmen and secretaries on our list.

Our Section is less than a year old, and as a consequence, we are not very strong yet, but we are gaining strength through coöperating with the Society of Engineers of Northwestern Pennsylvania, and on that account we are having fairly good meetings. An effort to increase the membership will be made, as at the present time we have only about twenty-six members.

Mr. Wallace (Indianapolis): The keynote of the Indianapolis Section has been coöperation. We have coöperated with the Indiana Mechanical Society at its annual meeting, by having one department of the program on one day.

The Indianapolis Section has been instrumental in organizing the Indianapolis Engineers' Club, which is a clearing house for all of the engineers in the city. Through the Club we fostered and organized the first battalion of engineers in the state of Indiana that has gone into the service.

Mr. White (Milwaukee): We have about one hundred members. Our activities can best be illustrated by saying that we have appointed a committee of twelve to draw up papers for the city of Milwaukee, in which they select engineers for city service. We have arranged for a meeting this month at which we will have a symposium on forgings, six speakers, and a visit to the largest forging plant in operation west of Pittsburgh. We are also doing something in research.

Mr. Brink (Minnesota): Our Section has about one hundred members. I think it is a mistake to have a Section to take in a whole state, because it is hard to get the members together at our meetings, although we have meetings alternately at St. Paul and Minneapolis, and occasionally, once a year or so, we meet in Duluth. We are trying to perform social work and also work on interesting papers. The Section this year has set out to get the A. S. M. E. Boiler Code adopted in Minnesota.

Mr. Hutson (New Orleans): Practically all of our work is done in coöperation with the Louisiana Engineering Society. That Society is about twenty years old, and a very live one. When our Local Section was first organized, we and the local Section of the A. S. C. E. held joint meetings in the rooms of the Louisiana Engineering Society, so that for all practical purposes they were extra meetings of that Society. One of those meetings was very successfully held about the time this country entered the war, and as the result of a paper on Preparedness the Louisiana Engineering Society made a roster of the engineers in Louisiana, with an entry of their capabilities.

This year it was arranged that we will be responsible for one meeting in the spring and one meeting in the fall, under the auspices of the Louisiana Engineering Society. Immediately after that meeting we have our business meeting, so that our business affairs are separate from those of the Louisiana Engineering Society, but all of our technical affairs are consolidated with it.

Mr. Prindle (New York): Our coöperation in New York with other scientific societies has consisted in our inviting the members of some particular society to meet with us at some of our meetings, where we had a paper which we thought was particularly interesting to the members of that Society, and such societies, on the other hand, have invited us to their meetings under like circumstances, and all have understood that the meetings of each society are open to the members of the other societies, but further than that we have not found it advisable to go as yet, because in New York the sections are so large the meetings become rather unwieldly where you combine two or more.

We have emphasized very much in the last year or two the get-together spirit, trying to break down the frigidity which exists in New York among people who do not know each other socially, and dinners and dinner dances and little buffet suppers just before the meetings have been used successfully.

Mr. Mudd (Philadelphia): We have the coöperation and affiliation idea in Philadelphia very nearly the same as the other Sections we have heard from. All the Branches of the National Engineering Societies have headquarters in the Philadelphia Engineers' Club. Last summer we had to raise a large amount of money to enlarge our auditorium, and the members of the Society succeeded in raising $32,000.

We opened the year with a joint meeting with the Engineers' Club, and the subject was The War in Its Relation to Shipbuilding. We had about 600 present, and probably one-third of those represented the A. S. M. E. Several of our papers were published in The Journal last year, and arrangements have been started to publish three of them this year. The remainder of the papers will be published in the Journal of the Engineers' Club.

Mr. Burlingame (Providence Engineering Society): Providence has a prosperous engineering society affiliated with the A.S.M.E. in a novel way. It was through the good offices of the A.S.M.E. that we enlarged our local society into a General Engineering Society which has now five or six hundred members, taking care of the general engineering interests in the neighborhood of Providence. That society is holding meetings under the leadership of a number of sections, eight sections hold meetings, so that we have about three meetings a week at our headquarters, besides the monthly meeting of the general engineering society. The local headquarters have been furnished by the liberality of a local member, who is also a member of the A.S.M.E., a lantern has been donated to us, and we have the nucleus of a very good library, so we feel especially indebted to the A.S.M.E. along all of these lines for the development and growth of our local work.

We have two local officers, a chairman and a secretary to each section, who divide the responsibility and give us a wide range of subjects. Our membership is increasing, and we feel that the society is a valuable factor in Providence in helping along the work of the Government. Many of our members are in the service, and others are working in connection with war committees on various kinds of work. I am a member of the New England Committee on the subject of intensified industrial training, the importance of which has been emphasized today.

Mr. Radcliffe (St. Louis): The St. Louis Section has about one hundred members. We are holding regular monthly meetings of a social nature, always followed by a paper or an address on an engineering subject. We are affiliated with the Engineers' Club, in what is known as the Associated Engineering Societies, which is made up of the local chapters of the national societies, with a total membership of about five hundred, but we still maintain a very strong individual identity as a local Section of the A.S.M.E.

If the Sections are to be the backbone of the Society, the best way that the Society can stiffen that backbone is to send members of the Council around to visit the members of the Section and stimulate their interest in the Section work. Only two or three of the local Sections can get in touch with headquarters, and the next best thing is to bring headquarters in touch with the members of the Society in their various localities.

Mr. Delany (San Francisco): The San Francisco Section, formed in 1910, is one of the oldest Sections in the Society. We have had one good meeting this year, for which we have to thank President Hollis. We invited the other sections of the various Societies to join with us, and they were quite enthusiastic in their responses. The meeting was very successful, and several members of the other Societies complimented us afterwards on the holding of this joint meeting, and expressed the hope that the other societies would do the same thing later.

We have had a good deal of difficulty in securing papers. We started by trying to secure papers by correspondence, and since then we have appointed a Papers Committee, and we expect results from that committee's work. We also have appointed a Research Committee, and during the present week there was to be a meeting of our Executive Committee with both the Papers Committee and the Research Committee, to find out just what progress is being made.

Mr. Fairfield (Worcester): The Worcester Section of the A.S.M.E. was formed to establish a means for engineering acquaintance and coöperation between the local members of the Society and the non-members who are engaged in our industrial firms. We have also established very close relations with the alumni and students of our local engineering college, the Worcester Polytechnic Institute.

Reports of Section Meetings

ATLANTA

November 6. The first meeting of the current fiscal year was held at the Hotel Ansley. The members were entertained at supper by the new chairman, Oscar Elsas, Mem.Am.Soc.M.E., after which Professor J. S. Coon delivered an interesting address on the subject of Aviation with Relation to the War. Following this routine business matters were discussed and most encouraging opinions were expressed regarding the remainder of the season. It was decided to hold meetings monthly and to have presented at each meeting either a paper or an address on an appropriate subject.

CECIL P. POOLE,
Section Secretary.

BOSTON

November 23. A dinner was held at the Engineers' Club, with President Hollis and President-Elect Charles T. Main, together with Mr. H. G. Smith, Vice-President and General Manager of the Fore River Shipbuilding Co., and Mr. E. H. Ewertz, General Superintendent of the Squantum Destroyer Plant of the Fore River Shipbuilding Co., as the guests of honor. After a short business session, Chairman Ashton turned the meeting over to President Hollis, who gave an entertaining and timely address, and then introduced Mr. Ewertz, who described the rapid building of the Squantum plant, which was an aviation field six weeks ago, but which is to deliver 35 submarine destroyers in sixteen months, beginning January 1, 1918. The plant is nearing completion at this time.

Mr. Smith delivered an address on the Recent Development of the American Marine Industry, approaching the subject not only from the engineering but from the production side, particularly with reference to the question of labor. He was later asked many questions as to various elements of the labor situation, and the discussion thus started, terminated in a very successful meeting.

W. G. STARKWEATHER,
Section Secretary.

BUFFALO

November 16. At the second general meeting of the Engineering ing Society of Buffalo, and its affiliated sections, Dr. C. H. Norton, Mem.Am.Soc.M.E., gave a talk on the Modern Cylindrical Grinding Machine. Dr. Norton illustrated his lecture and cited many interesting points in the design of grinding machinery.

L. H. Hart, engineer for Lupfer & Remick, Civil Engineers, spoke on the subject of Electricity on the Barge Canal, at the November 21 meeting of the society. Mr. Hart pictured a barge canal electrically operated by a push-button type of boat, and predicted that these boats would be run on the canal eight months of the year. This canal would relieve railroads of bulk freight and give them greater opportunity for development in carrying other lines.

At a meeting of the Automotive Section of the society, on December 6, G. Douglass Wardrop, Editor of the *Aerial Age*, talked on Aeroplanes, Uncle Sam's Infant Industry. He illustrated his subject by numerous lantern slides and several reels of films. Quoting Mr. Wardrop:

"A wedge will soon be driven through the lines of the German armies, and I believe that the point of that wedge of liberty will be the aeroplane.

"Young men in Buffalo will have the satisfaction of knowing that on many of those planes the name of Buffalo will be stamped somewhere in their mechanism.

"The aeroplane is the greatest factor we have now for the advancement of civilization. It is the wedge-point of liberty. Buffalo is now the leading aviation center in this country. In a short time it will be the greatest single aviation center in the world. But you Buffalo people will have to work hard indeed if you want to keep that supremacy. Detroit has got the automobile industry practically to herself, and she is trying to do the same with aviation. Detroit now stands second, and is rapidly increasing her importance as a producing center for aeroplanes and their parts."

Among the interesting applications of the aeroplane Mr. Wardrop showed the picture of a Montana ranchman using an aeroplane to round up his cattle. He flies over his wide plains and drops a smoke bomb when he finds the straying herds. The cowboys note the fall of the bomb and hurry to the spot. He showed pictures of inaccessible mining districts, wealthy in resources beyond present computation, but lightly worked now because of the enormous cost of transportation, that could be reached in an hour by the use of aircraft.

The society held another meeting on December 12, at which F. A. Parkhurst, Mem.Am.Soc.M.E., spoke on The Mobilization of Labor. A fuller account of this meeting will be given in the following issue of THE JOURNAL.

LOUIS J. FOLEY,
Assistant to Section Secretary.

CHICAGO

November 16. President Hollis and several members of the Council were present at the first meeting of the Section for the season. Dr. Hollis addressed the audience on the engineer's task in the present war. He said that the terrible effectiveness of modern warfare is due largely to inventions of the engineer, and it now lies with the engineering profession to say whether the results of its work shall be only to make war more horrible, or whether by its influence it shall be possible to make the present war the last one, and to determine that coöperation and the use of the engineering inventions shall be for the happiness of the people instead of their hurt. If increased efficiency of human effort is to mean simply an increase of population which will result in a greater struggle for dominion and greater effectiveness in killing, it is not worth having. Dr. Hollis spoke of the effectiveness which engineers may have in helping the officials who are charged with conservation or resources, by acting in consulting capacity on such matters as fuel conservation, and by acting as speakers to educate the public in the necessity for and the methods of preventing waste of food and fuel.

Major Peter Junkersfeld, Mem.Am.Soc.M.E., delivered the principal address of the evening on Cantonment Construction, giving much information and data in regard to his work in the cantonments. In his capacity as officer in charge of inspection, he had had exceptional opportunity to gather information and presented a most instructive paper, which will be published in full later.

Altogether the evening was a great success, the meeting being the most enthusiastic and best-attended since the inception of the Section.

ARTHUR L. RICE,
Section Secretary.

ERIE

November 13. Pulverized Coal and its Future was the subject of an address by H. G. Barnhurst, Mem.Am.Soc.M.E., at a joint meeting of the Section with the Engineers' Society of Northwestern Pennsylvania. The meeting was opened by Mr. Schumm, President of the Engineers' Society of Northwestern Pennsylvania. The speaker of the evening gave a most interesting account of the developments in the use of pulverized coal as fuel.

M. E. SHERWOOD,
Section Secretary.

INDIANAPOLIS

November 7. L. O. Armstrong, who is traveling under the auspices of the Bureau of Economics of the United States Government, gave an illustrated address. Mr. Armstrong is endeavoring to stimulate interest and enthusiasm for all efforts of the Government in carrying on the war. His talk was valuable, profitable and very much appreciated. His subject was Canada at War, and was well illustrated by motion pictures and lantern slides.

At the same meeting Captain Brown, of the Canadian Engineers, gave a short talk pertaining to his experiences in the trenches in France. Captain Brown is back in this country on a sick leave, and while here is the recruiting officer for the Canadian Government in the city of Indianapolis.

Captain Reeves, of the United States Army, also gave a very interesting talk concerning the qualifications required by young men for the aviation service. Captain Reeves is the local recruiting officer for the Aviation Section of the United States Army. He was for many years professor of economics at the University of Michigan at Ann Arbor.

L. W. WALLACE,
Section Correspondent.

LOS ANGELES

November 24. The meeting of the Technical Societies of Los Angeles took the form of an automobile trip to the top of Mt. Wilson, the occasion being a visit to the Mt. Wilson Solar Observatory. The exciting part of the trip was that of climbing from an altitude of 1500 ft. at the base of the mountain to 5600 ft. at the top, which is a distance of nine miles. The new one-hundred inch telescope, the largest in the world, proved the principal object of interest, as it is nearing completion. The greater part of the excursionists "stargazed" until after midnight.

T. J. Royer,
Section Secretary.

MILWAUKEE

November 14. B. E. Fernow, Jr., gave an illustrated talk on the Design and Application of Magnetic Clutches. Mr. Fernow showed a great number of interesting pictures and demonstrated an actual clutch.

Following the meeting there was a general discussion, after which a buffet luncheon was served.

F. H. Dorner,
Section Secretary.

PHILADELPHIA

November 27. This meeting of the Section was opened with a statement of the progress being made by the various sections, by D. Robert Yarnall, Chairman of the Committee on Sections. Mr. Yarnall emphasized the fact that some of the newer western sections are extremely active and progressive. Mr. Ernest Hartford, secretary of the Committee on Sections, spoke upon the subject of section activities. A motion made by Mr. L. H. Kenny was carried, directing that the chairman appoint a committee on papers. Prof. Walter Rautenstrauch, member of the Committee on Sections, presented the paper of the evening, entitled Manufacturing in Relation to Banking, Research and Management.

Offensive Against the Submarine, by Joseph A. Steinmetz, was the subject of the evening at a joint meeting of the Section with The Franklin Institute on December 11. A complete report of this meeting will be given in the following issue of The Journal.

John P. Mudd,
Section Secretary.

PROVIDENCE

December 10. Frederick J. Hoxie, Mem.Am.Soc.M.E., spoke before the Fire Insurance Engineering Section, giving a most interesting paper on the Fire Hazards of Celluloid. On Tuesday, December 11, the Designers and Draughtsmen Section listened to a paper by J. S. White, of the Morse Chain Company, Ithaca, New York, who talked mainly on the engineering of silent-chain drives; a very interesting discussion followed. On December 12, George F. Wheaton, of the J. & P. Coats, Ltd., read a paper on Boiler Efficiencies before the Power Section. The Brown University Student Section of the Providence Engineering Society held a meeting on this date, at which Professor Hardy Cross gave a paper on How an Engineer Gets His Facts.

James A. Hall,
Correspondent.

ST. LOUIS

November 9. The Associated Engineering Societies of St. Louis held a farewell testimonial dinner tendered to John Hunter, Mem. Am.Soc.M.E., who for the past twelve years has been Chief Engineer of the Union Electric Light and Power Company, and who has recently been called into the service of the Government in the capacity of district manager for the Emergency Shipbuilding Corporation, with headquarters in New York. The occasion found the Engineers of St. Louis meeting with mingled feelings; pride that one of their members had been chosen for this important work, and regret that they were to lose a man who had done so much for the profession during his many years' residence in St. Louis, and who had made a friend of every engineer with whom he had come in personal contact. Mr. Hunter has always taken active interest in the work of The American Society of Mechanical Engineers and has been elected Vice-President for the coming year.

The regular monthly meeting of the Section was held on November 23, at which the affairs of the Society were discussed, and a resolution adopted to the effect that the Executive Committee of the St. Louis Section extend to the Council a cordial invitation to hold a meeting in St. Louis at such time as may be found most convenient.

H. W. Radcliffe,
Section Chairman.

WORCESTER

November 22. The first meeting of the Worcester Section was held in the Electrical Building of the Worcester Polytechnic Institute, and the subject presented for discussion was Fuel Conservation. The section was fortunate enough to secure Dr. Ira N. Hollis, President of the Society, and Prof. L. P. Breckenridge, Mem.Am.Soc.M.E., to open the discussion. Dr. Hollis took up the broader view of conservation as it appertained to all our resources, emphasizing the point that some of our resources, such as our foods, are recurring crops, while others, like coal, once used are gone forever.

Professor Breckenridge dealt with the conserving of our coal supply. He displayed lantern slides, showing where the coal is used and what industries are the largest users. He closed his presentation of the subject by outlining the ways in which coal can be saved.

Previous to the discussion, a buffet luncheon was served at the home of Dr. Hollis.

H. P. Fairfield,
Section Secretary.

STUDENT BRANCHES

Conference of Student Branches

At the Student Branch Conference held on Wednesday, December 5, in connection with the Annual Meeting, much was developed of interest, and although it was found that our Branches have lost a great percentage of their members due to the war, plans are being laid to carry on their activities as in previous years.

The representatives of the following colleges were present, and gave brief talks on how the war had affected the conduct of their affairs, and what plans were being laid for future meetings:

Armour Institute of Technology.......Mr. A. H. Anderson
State University of Iowa....................Mr. Sheatsley
State University of Kentucky......Prof. F. Paul Anderson
Massachusetts Institute of Technology......Mr. A. Saunders
New York University.....................Mr. H. G. Tyler
Polytechnic Institute of Brooklyn.........Mr. Wm. Sumner
Rensselaer Polytechnic Institute............Mr. R. P. Kolb
Stevens Institute of Technology.............Mr. McDermot
University of Washington....................Mr. McCoy
Worcester Polytechnic Institute............Mr. R. C. Lewis
Yale University..........................Mr. R. Wier, Jr.

While some of the colleges have been affected less seriously than others, none have escaped without feeling some strain of the present war conditions. Massachusetts Institute of Technology reported a loss of 50 per cent of its members and a number of the other colleges reported losses from 30 per cent to 50 per cent. With the provision just made by the Government to enlist all engineering students in the Engineer Reserve, and to

exempt them from the national draft, many more men will now probably stay in the institutions and complete their courses.

On account of the loss of professors in the various colleges a great many courses have been eliminated from the college curricula entirely and outdoor drills substituted. While the kind of training varies in the different colleges, nearly every college devotes part of the time to military training. Reports from a few of the colleges in this connection follow:

At Columbia University a complete submarine has been installed in the laboratory and the students are instructed in the testing of motors, engines, etc. In Cambridge are the aviation school and the only naval school of its kind in the country. At Ohio State University there is an aviation school. At Stevens Institute of Technology military drills are required two days a week; Stevens has received an assignment of guns and the students receive instructions in the manual of arms. While it has been a regular requirement at the University of Washington since 1909 that strict military training is required for two years, this training has now been made more severe and students receive instructions under the supervision of U. S. Army officers and have three drill parades a week. Yale University has thirty horses which are utilized in the artillery training the students are receiving.

F. R. Hutton, *Chairman*,
Committee on Student Branches.

Student Branch Meetings

(Some of the Student Branch Reports are unavoidably held over on account of lack of space, but will be published in the February issue.)

ARMOUR INSTITUTE OF TECHNOLOGY

November 27. One of the main objects of the Branch this season is to have short talks given by three or four members of the Society, on some technical subject. At the last meeting K. A. Taylor spoke on the construction, assembling and testing of different types of Fairbanks-Morse Gas Engines. Mr. Rehfelt discussed the modern dispensing machine, such as the type used in the automatic restaurant. Mr. Wutheimer spoke on the design, remodeling, process of construction, and routing through the shops of different types of valves as used on gasoline motors, as made by the American Car & Foundry Company.

The officers of the Branch for the coming year are as follows: President, D. A. Taylor; vice-president, J. A. Keeth; secretary, V. A. Kerr; treasurer, H. Anderson.

The Armour Institute of Technology has discontinued athletics this year, although it strongly advises its students to make use of the gymnasium to keep themselves fit for Government service, and has made it compulsory that the freshmen and sophomores take military training one afternoon a week. The training is left optional to the junior and senior classes, but a large majority of both upper classes are drilling.

Under the instruction of Professor Libby and Professor Pebbles, a class of marine engineers is now meeting four times a week.

V. A. Kerr,
Branch Secretary.

UNIVERSITY OF CINCINNATI

October 19. The spirit and ardor shown at the first meeting of the season gave every indication that the Branch would be very active this year. An entertainment and membership committee, along with a new publicity man, were appointed. An orchestra and several good speakers was the program offered for the evening. Among other visitors several of the alumni of the Engineering College, along with a few professors, were present. J. B. Stanwood, Mem.Am.Soc.M.E., gave a very interesting talk on The Power to Visualize Objects of Study. He suggested that engineering problems be solved, as far as possible, by means of a rational reasoning process rather than by the use of handbook rules and formulæ. Mr. Stanwood solved several problems dealing with the valve motion of the simple slide-valve engine to illustrate his remarks. Professors Jenkins and Joerger also addressed the students and strongly advocated Mr. Stanwood's ideas.

At the second meeting of the Branch on November 23, Wm. A. Greaves, of the Greaves-Klusman Tool Company, Cincinnati, spoke of his engineering experiences. The talk presented many interesting problems such as the repairing of very large anchors, the underlying principle of the building of the Mississippi Jetties, and Captain Eads's ship railway. The speaker concluded his talk by urging the students to do everything in life with a determination to win.

It was decided at this meeting to make an inspection trip to the new plant of the Union Gas & Electric Company, now under construction. At the present time the construction company is placing the condensers and the boilers. This plant is to be one of the largest of its kind in that part of the country. Up to the present time the students have been studying the foundation as a part of their steam-power-plant course in steam engineering.

C. L. Koehler,
Branch Secretary.

LEHIGH UNIVERSITY

November 12. The first meeting of the Branch for the season was given over entirely to a business session and the electing of the officers for the present year, which resulted in the following: President, W. R. Penman; secretary, N. Dmytrow; treasurer, R. M. Stettler.

P. B. de Schweinitz,
Honorary Chairman.

UNIVERSITY OF MAINE

November 23. The first meeting of the Branch for the season was given over to a short business session, and the electing of the new officers for the present year, which resulted in the election of I. L. Newman, president; I. S. Hanson, vice-president; D. F. Theriault, secretary and treasurer; A. F. Barnard, R. L. Googins, K. B. Noyes, as the Executive Committee, and Prof. W. J. Sweetser, Mem.Am.Soc.M.E., Honorary Chairman.

D. F. Theriault,
Branch Secretary.

MICHIGAN AGRICULTURAL COLLEGE

November 1. The first meeting of the Branch for the season was given over entirely to the electing of the new officers for the present year, and the discussion of campaigns for membership. The results of the election were as follows: President, H. T. Froelich; vice-president, W. G. Retzlaff; secretary, H. M. Sass; treasurer, F. O. Stang.

H. M. Sass,
Branch Secretary.

PENNSYLVANIA STATE COLLEGE

November 16. The first meeting of the Branch for the season began by a short business session, after which the meeting was turned over to the Program Committee. Prof. R. B. Fehr, Mem.Am.Soc.M.E., gave an illustrated talk on the romantic development of the steam engine, beginning with the earliest forms of which there is any record and tracing its development to the present day. Dean R. L. Sackett gave a short talk to the students with reference to the activities of the Branch. There followed a few selections by the Mandolin Club, after which refreshments were served. Prof. E. A. Fessenden, Mem.Am.Soc.M.E., Professor Resides, and Prof. A. F. Wood, Mem.Am.Soc.M.E., then gave short talks, completing the program of a very successful evening.

H. W. Parthesun,
Branch Secretary.

THROOP COLLEGE OF TECHNOLOGY

November 8. Dr. Ira N. Hollis, Pres.Am.Soc.M.E., was present as speaker and guest of honor at the opening meeting of the Branch this year. Dr. Hollis addressed the students on the War, Conservation, The Part of Engineering in the War, and told his philosophy of life. Everyone present was much impressed by

this stirring address and the true simplicity of this really great man.

Because of the enlistment of so many of its students the Branch has had some difficulty in organizing this year. Plans have been made to coöperate with the Student Branch of the American Institute of Electrical Engineers, and to have joint meetings once a month. The outlook for a successful year is very good so far.

Retla Alter,
Branch Secretary.

UNIVERSITY OF WASHINGTON

November 16. K. B. Sallee was elected corresponding secretary, and the following Committees appointed: Program committee, Prof. J. H. Macintire, *chairman*, Buel B. Blake, and Earl Elvidge; election committee, Valentine Hoffman, *chairman*, Lester R. McLeed, and Leroy Burque. Jasper F. Keuhnert was elected freshman representative, and Arthur W. Stewart sophomore representative. Plans were completed for the coming smoker which it was decided to hold on November 22, at 8 p. m.

K. B. Sallee,
Branch Secretary.

WASHINGTON UNIVERSITY

November 7. The first meeting of the season resulted in the following elections: Chairman, Ernest E. Bissett; vice-president, Francis Packer; secretary, Fairman B. Lee; treasurer, Corwin P. Rummel. Plans for future meetings and a smoker were discussed, after which Professor Macintire gave a short talk on the aims and ideas of the Society. Representatives from the freshman and sophomore classes were appointed to get all underclassmen interested.

Fairman B. Lee,
Branch Secretary.

UNIVERSITY OF WISCONSIN

October 18. The season opened with a well attended business meeting and was followed by a talk given by Professor Corp, Mem. Am.Soc.M.E., on the purpose of the Society and the benefits derived by the members.

At the November 11 meeting of the Branch, Mr. Stocker gave an illustrated lecture on his work and experiences in China. He gave a very good description of the life, customs, habits and methods of the Chinese. A business session followed at which the names of the men applying for membership were read for the second time, and the date of initiation was set for Thursday night, November 15.

The December 6 meeting consisted of an interesting and complete talk on Gas Turbines by Glenn Warren. Mr. Warren has spent a great deal of time studying gas turbines, and was therefore well qualified to speak on this subject.

H. K. Shieks,
Branch Secretary.

WORCESTER POLYTECHNIC INSTITUTE

November 16. The November meeting of the Student Branch was made especially interesting by a discourse on Employment Relations Work, by E. H. Fish, Employment Manager of the Norton Co. The speaker emphasized the attempts made by employer experts to reëstablish the old cordial relations between the employed and the employer. He also told how the up-to-date employment manager coöperated with the welfare work among the employees, even assisting in the employees' home in times of great stress of sickness. In closing he called attention to the present lack of skilled workmen and showed how the Norton Companies established their records of employees as related to the working ability, ambitions, health, etc., of the individual as a means of putting the right man in his proper place.

On December 7, the Branch held a joint meeting with the American Institution of Electrical Engineers, in the Electrical Building. The meeting was opened by Benjamin Luther, chairman of the A.I.E.E. Branch, who introduced Mr. Geo. M. Eaton, W.P.I., '96, now head of the Railway Division of the Westinghouse Electric & Manufacturing Co. Mr. Eaton gave an illustrated lecture on The Other Half of Engineering, and showed how a new machine or apparatus is seldom in its best form as first designed and tested. By displaying a variety of designs the speaker showed how new goods are often defective, as first constructed, and how these inevitable defects are corrected. The talk was both instructive and unique, inasmuch as it dealt with the difficulties of engineering rather than with the successes. Mr. Eaton showed the students that an engineer's job sometimes is that of pulling batters out of a hole and is not always easy.

H. P. Fairfield,
Branch Secretary.

KANSAS STATE AGRICULTURAL COLLEGE

November 22. James I. Brady, senior in mechanical engineering, gave a paper entitled Ordnance Work. He dwelt upon the organization of the Ordnance Department and the importance of the work at the present time, laying emphasis on the part technically trained men might perform in this field of work. The second number on the program was a review of the September issue of The Journal, presented by Mr. Harry Bell, Junior in Mechanical Engineering. Mr. Bell laid special emphasis on the article of "Modern Locomotive Practice."

At the December 6 meeting of the Branch Seibert Fairman presented a paper entitled Aviation Training. The subject matter was gathered from current magazines and from reports of students of this school who are at present training as aviators. This subject proved very interesting and of much importance because of the fact that a large per cent of the students are entering the aviation service of the Government. Mr. Gordon Hamilton, junior in mechanical engineering, presented a review of the November issue of The Journal. Mr. Hamilton in his review spoke on the two articles of Accident Prevention, and Labor Turnover Records and the Labor Problems.

I. O. Mall,
Branch Secretary.

College Reunions

The College Reunions were held on Friday night of the Annual Meeting as in previous years, and if the war lessened the number somewhat, nevertheless the reunions that were held were very thoroughly enjoyed.

The Cornell reunion had as its guests Mr. Lawrence Sperry, Prof. D. S. Kimball and Mr. Robert Lee. Mr. Sperry gave an interesting talk of his "flying" experiences; Professor Kimball spoke on the wartime conditions at the University and Mr. Lee illustrated his talk on the gyroscope with lantern slides and models. Mr. C. F. Hirschfeld and Mr. W. W. Macon acted as toastmasters at the dinner.

The Massachusetts Institute of Technology had forty A.S.M.E. members at its reunion at the Technology Club. After an informal dinner Mr. James P. Munroe, '82, gave a talk on Washington in War Times.

Purdue held its annual reunion at the Phi Gamma Delta Club, and over thirty members were present, including as guests Dr. W. F. M. Goss, Prof. C. A. Waldo, Dean C. H. Benjamin and Mr. Angus Sinclair, all of whom gave very interesting talks. Dean Benjamin spoke on what the University and graduates are doing for their country at the present time, while Dr. Goss brought home forcibly the necessity of conserving the number of men training for the engineering profession. Congratulations were telegraphed the University on its patriotic help and services at this time.

Stevens Institute of Technology gave a supper dance at the Hotel Astor, omitting their usual theater party in view of the seriousness of the times. The dance was most successful and voted by all one of the most enjoyable dances ever given by Stevens.

The University of Kentucky N. Y. Club held an informal smoker at Keen's Chop House, having as their guests the out-of-town alumni who were in the city attending the Annual Meeting, as well as several other engineers that Kentucky would be proud to claim as hers. Professor Anderson, dean of the mechanical and electrical colleges of the University, and President Wendt of the Buffalo Forge Co. gave very interesting impromptu talks. The attendance was somewhat reduced owing to the fact that so many Kentucky men are in the national service.

Worcester Polytechnic Institute held its reunion in the Society rooms. Following a buffet supper remarks were made by three Past-Presidents of the Society, Dr. Ambrose Swasey, Dr. John A. Brashear and Dr. Ira N. Hollis, President of the Institute. The other guests who addressed the meeting were Prof. M. E. Cooley, of the University of Michigan, and Prof. Chas. M. Allen, of Worcester, who gave an interesting account of the present activities of the Institute.

ROLL OF HONOR

THE SOCIETY'S SERVICE FLAG unfurled at the Annual Meeting bore the number 433 in stars, which was the total number of members in the Service of which the Society had notification on December 4, 1917. This new list of names received since the publication of the previous list brings the total to nearly 600.

ADAMS, PORTER H., Office of Naval Intelligence, United States Navy.
ADAMSON, KEITH F., Captain, Inf. U. S. R., U. S. Expeditionary Forces.
ALISON, E. E., Major, Production Section, Gun Division, Ordnance Department, U. S. R.
AUSTIN, RICHARD S., Aviation Student, Division 5, Foreign Detachment, American Expeditionary Forces.

BACON, HOWARD E., Company C, 318 Field Signal Battalion, Camp Jackson, Columbia, S. C.
BAIRD, JAMES T., JR., Captain, Ordnance Department, United States Reserve.
BALDWIN, BERT L., Major, Engineer Officers' Reserve Corps.
BASSETT, CHARLES K., Lieutenant, Ordnance Department, United States Reserve.
BEEBE, LAWRENCE L., Captain, Engineer Officers' Reserve Corps.
BEHR, F. J., Major, Coast Artillery Corps, United States Army.
BENEDICT, BYRON W., First Lieutenant, Ordnance Section, Oficers Reserve Corps, United States Army.
BENHAM, W. L., Major, Quartermaster Officers' Reserve Corps, Camp Funston, Ft. Riley, Kan.
BENSON, H. S., First Lieutenant, Ordnance Department, Inspection Section, U. S. R.
BILLINGS, A. W. K., Lieut.-Commander, care of Commander U. S. Naval Aviation Forces, Paris, France.
BIRDSEYE, GARNER K., First Class Private, Aviation Section, Signal Corps, United States Army.
BOWES, LAWRENCE C., 332nd Field Artillery, U. S. A.
BOYD, FRANK F., Lieutenant, United States Naval Reserve Force.
BRADFORD, J. S., Captain, 103rd Engineers, Company B, Camp Hancock, Augusta, Ga.
BRADY, GEORGE S., Captain, American Ordnance Base Depot in France.
BREADY, WILLIAM M., JR., First Lieutenant, 108th Engineers, Company E, 33rd Division, Camp Logan, Texas.
BREWSTER, HENRY B., Captain, 303rd Regiment of Engineers, Camp Dix, N. J.
BROWN, EDWARD W., Lieutenant, United States Naval Reserve Force.
BUCKLEY, JOHN H., Captain, Equipment Engineer, Small Arms Division, Frankford Arsenal.
BYLLESBY, H. M., Major, U. S. R., Signal Corps Headquarters.

CAHILL, EDWARD H., First Lieutenant, Field Artillery Section, Carriage Division, Ordnance Department.
CAMPBELL, JEREMIAH, Major of Engineers, United States Reserve Corps, American Expeditionary Force, France.
CARPENTER, CHARLES A., First Lieutenant, Ordnance Section, Officers' Reserve Corps, United States Army.
CHAPIN, WARREN W., Captain, Engineers, United States Reserve.
CHRISTIE, A. G., Private, Reserve Officers' Training Corps, Johns Hopkins University.
CHURCH, ELIHU C., Captain, Engineer Officers' Reserve Corps, Adjutant 117th Engineer Regiment, 42nd Division.
CLARK, JOHN W., Second Lieutenant, Engineer Officers' Reserve Corps, United States Army.
CLAUSSEN, HOWARD P., Ensign, United States Naval Reserve Force, Class 5 (Naval Reserve Flying Corps).
CLEMONS, ROBERT S., Major, Commanding 506th Engineering Service Bureau, Camp Lee, Va.
CLUCAS, GEORGE W., Private, Company G, First Reg. 122 Reserve Militia.
COHEN, ABRAHAM SAUL, First Lieutenant, Ordnance Reserve Corps, United States Army.
COLE, C. S., Captain, Ordnance Reserves.
CONANT, WILLIAM S., Captain, Ordnance Officers' Reserve Corps.
CONROY, RAYMOND, Second Lieutenant, Coast Artillery Corps, United States Army.
COOK, WILLIAM P., JR., First Lieutenant, Ordnance Officers' Reserve Corps.
CYPHERS, JAMES F., First Lieutenant, Ordnance Officers' Reserve Corps.

DAILEY, FRED A., Captain, Engineer Officers' Reserve Corps.
DELEMOS, FREDERICK P., Second Lieutenant, Infantry Officers' Reserve Corps.
DE VISSER, JOHN H., Captain, Officers' Reserve Corps, Ordnance Department, Supply Division.
DEXTER, HARRIS E., Lieutenant, 30th Engineers (Gas and Flame).
DICKERSON, H. S., Captain, United States Reserve.
DIEMER, HUGO, Major, Ordnance Officers' Reserve Corps.
DIETRICH, FRED E., Machinist's Mate, Second Class, Naval Coast Defense Reserve.
DRESSLER, L. RICHARD, First Lieutenant, Ordnance Department, Carriage Division, Officers' Reserve Corps.
DREW, WILLIAM N., Second Lieutenant, 323rd Field Artillery.
DUNCAN, J. C., Captain, Quartermaster Corps, U. S. R.

EATON, P. B., Second Lieutenant of Engineers, United States Coast Guard.
EDE, ALBERT B., Second Lieutenant, Coast Artillery Corps, U. S. A., American Expeditionary Forces.
EDMONDSON, RALPH S., First Lieutenant, 27th Engineers, Engineers' Reserve Corps.
ESTABROOK, M., Captain, Ordnance Department, United States Army.
EVANS, GEORGE A., Lieutenant (Junior Grade), United States Naval Reserve Force.
EVANS, LYNN B., Ensign, United States Naval Reserve Force.
FABENS, ANDREW L., First Lieutenant, Ordnance Reserve Corps.

FERNSTROM, F. S., United States Naval Reserve Force.
FESSENDEN, C. H., Captain, Ordnance Reserve Corps, Ordnance Department, Frankford Arsenal, Philadelphia, Pa.
FIELD, FREDERICK C., Captain, Ordnance Officers' Reserve Corps, Small Arms Division, Ordnance Department.
FISH, M. R., Private, Mass. State Guard, Company H., 19th Regiment.
FISHER, R. R., First Lieutenant, 106th Engineers, 31st Division, Camp Wheeler, Macon, Ga.
FISHLEIGH, WALTER T., Major, Sanitary Corps, N. A., Surgeon General's Office, Washington, D. C.
FORDYCE, JOHN R., Major Engineers, U. S. R.
FORFAR, DONALD M., First Lieutenant Engineers, U. S. R. Engineer Officers' Reserve Corps.
FOWLER, WALLACE S., First Lieutenant, Ordnance Officers' Reserve Corps, Production Section, Carriage Division.
FOSTER, ERNEST H., Ensign, United States Naval Reserve, Class No. 4.
FRANCE, JOHN E., First Lieutenant, Engineer Officers' Reserve Corps, 5th Engineer Corps, Company F.
FRANKET, WILLIAM F., Second Lieutenant, Ordnance Officers' Reserve Corps.
FRANKLIN, BENJAMIN A., Major, Ordnance Department.
FREDERICK, ALVAH B., Second Lieutenant, Ordnance Officers' Reserve Corps.
FREEMAN, B. W., First Lieutenant, Ordnance Department.
FRIEDMAN, FERDINAND J., First Lieutenant, Supply Division, Ordnance Department, U. S. R.
FRITZ, A. L. G., Cadet, Squadron B, Signal Corps, Aviation Section, Officers' Reserve Corps, United States Army, Wright Field, Dayton, Ohio.

GIBBS, PAUL H., First Lieutenant, Ordnance Department, Inspection Section, Gun Division, U. S. R.
GILSON, JOSEPH L., Corporal, Company F, 302nd Engineers, United States Army.
GITHENS, THOMAS F., First Lieutenant, Ordnance U. S. R., Trench Motor Design.
GLEASON, GILBERT H., Trooper, First Troop (Cavalry) Mass. State Guard.
GRAY, H. LIGGETT, Chief Machinist's Mate, U. S. Naval Reserve.
GREENE, AUGUSTINE E., Major, Ordnance Officers' Reserve Corps.
GREENLEAF, GEORGE E., Major, Ordnance Bureau, United States Army.
GREF, W. H., Lieutenant, Torresdale Station, Philadelphia, Pa.
GUEST, W. E., Captain, Ordnance Officers' Reserve Corps.

HANSEN, F. D., First Lieutenant, Reserve Corps, Ordnance Department.
HARKNESS, V. F., Lieutenant (Junior Grade), United States Naval Reserve Force.
HENRY, VERNOR S., First Lieutenant, Ordnance Department, United States Reserve.
HERRICKS, E. A., Captain, Ordnance Officers' Reserve Corps.
HOBBS, GEORGE W., First Lieutenant, Ordnance Section, Officers' Reserve Corps.
HOFFMAN, JOHN ERNEST, Second Lieutenant, Engineer Officers' Reserve Corps, American Expeditionary Forces.
HORTON, ELIAS Q., Ensign, U. S. Naval Reserve Force, on board U. S. S. South Carolina.
HOWARTH, JACOB M., First Lieutenant, Officers' Reserve Corps, Intelligence Officer, 342nd Inf. Headquarters, Camp Grant, Ill.
HUBBELL, ARTHUR C., First Lieutenant, Purchase Section Small Arms Division, Ordnance Department.
HUNICKE, C. CAMPBELL, Sub-Inspector of Ordnance, Ordnance Department, United States Navy.
HUNT, H. B., Major, Ordnance Department, Gun Division.
HUNTER, CHARLES F., Captain, Ordnance Reserve Corps.

Jackson, John P., Major, Engineer Officers' Reserve Corps.

Kaemmerling, Gustav H., Second Lieutenant, U. S. M. C., First Aviation Squadron.
Kehl, R. J., First Lieutenant, Division of American Ordnance Base Depot in France.
Kellogg, Charles D., First Lieutenant, Ordnance Department, Small Arms Division.
Knowlton, F. K., Captain, Ordnance Reserve Corps, United States Army.
Lambelet, Carl H., First Lieutenant, Ordnance Department, United States Reserve.

Lamoree, J. K., First Lieutenant, Engineers, U. S. R., Officers' Reserve Corps, Engineer Section.
Lancaster, William C., Captain, Engineer Officers' Reserve Corps.
Langville, H. B., Lieutenant (Junior Grade), Naval Coast Defense Reserve, U. S. Naval Reserve Force.
Leonard, Elton Ibbotson, Canadian Expeditionary Force in France.
Leisen, Theodore A., Major, Quartermaster Corps, Utilities Department, 85th Div., U. S. Army.
Lewis, Kenneth B., Private, Company H, 19th Infantry, Mass. State Guard.
Lightowler, George R., First Lieutenant, Ordnance Reserve Corps, Watertown Arsenal.
Luehrmann, Hugh, Second Lieutenant, Signal Reserve Corps, U. S. School for Military Aeronautics, Cornell University, Ithaca, N. Y.
Lyon, Percy S., Captain, Coast Artillery Reserve Corps, Ft. Monroe, Va.
Lyster, Thomas L. B., Major, U. S. A., Air Service, American Expeditionary Forces, France.
Lytle, Charles W., Private, Aviation Section, Enlisted Reserve Corps.

McGrew, J. A., Major, Quartermaster Reserve Corps, Cantonment Constructing Department.
McKissick, Ellison S., First Lieutenant, Company F, 306th Engineers, U. S. R.
Marshall, Harold F., First Lieutenant, Aviation Section, Signal Officers' Reserve Corps, United States Army.
Metcalf, George R., First Lieutenant, Ordnance Officers' Reserve Corps, Fort Hancock, N. J.
Miltenberger, George K., First Lieutenant Engineers, United States Reserve, Company D, 314th Engineers, 89th Division, Camp Funston, Kan.
Mixter, George W., Major, Signal Corps, Equipment Division.
Monaghan, James F., Captain, Ordnance Officers' Reserve Corps, United States Army.
Morgan, John D., First Lieutenant, Engineer Officers' Reserve Corps.
Morris, Thomas B., First Lieutenant, Engineers, United States Reserve.
Murrie, John L., Lieutenant, United States Naval Reserve Force.

Neidig, W. N., First Lieutenant, Signal Corps, United States Reserve, Construction Division, Aviation Section.
Newcomb, Benjamin R., First Lieutenant, Ordnance Reserve Corps, United States Army.
Newcomb, Franklin L., First Lieutenant, Company C, 24th Regiment of Engineers, Engineers Reserve Corps.
Nielsen, Lawrence H., Naval Reserve Flying Corps.

Oberlin, E. G., Lieutenant Commander, United States Navy.
Obrison, Thomas E., First Lieutenant Engineers, U. S. R., 2nd Company, 2nd Engineers Officers' Training Camp, Fort Leavenworth, Kan.

Pancoast, Fred L., Captain, Ordnance Department, United States Reserve.
Parr, Harry L., Lieutenant, United States Naval Reserve Force.
Penney, Rupert L., Captain, Ordnance Officers' Reserve Corps.
Perry, E. D., First Lieutenant, Equipment Division, Purchasing Section, Ordnance Corps.
Peters, H., Signal Corps, U. S. A., Inspection and Specifications Section.
Pope, Clarence James, First Lieutenant, Ordnance Department, U. S. R., Motor Section.
Pope, Frederick, Captain, 30th Engineers, Gas and Flame Division.

Reimer, A. A., Major, 305th Engineers, 80th Division.
Reitz, Walter R., First Lieutenant, Ordnance Department, U. S. A.
Rhame, Frank P., First Lieutenant, Ordnance Department, United States Reserve, Inspection Section.
Ripley, William H., First Lieutenant, Ordnance Department, United States Reserve.
Rittenour, Frederick H., Captain, Engineer Officers' Reserve Corps.
Rockwell, Sherburne B., Chief Petty Officer, U. S. Navy, on board U. S. S. Noma.
Roesen, Robert H., Sergeant, Company D, 302nd Engineers, National Army.
Rose, C. E., Captain, Engineer Officers' Reserve Corps.
Ross, Cleland Coldwell, First Lieutenant, Ordnance Reserve Corps, Fort Hancock, N. J.

Sampter, Herbert C., Aviation Section, Signal Corps, Enlisted Reserve, U. S. A.
Samson, Charles L., First Lieutenant, Engineer Officers' Reserve Corps.
Savage, L. L., Lieutenant, 309th Engineer Regiment, U. S. A.
Schmidt, Edward C., Major, Ordnance Reserve Corps, Carriage Division, Inspection Section.
Schwenker, Robert F., Second Lieutenant, Field Artillery, Officers' Reserve Corps, U. S. A.
Sedgwick, H. A., Prov. Lieutenant Commander, United States Naval Reserve Force.
Seed, Charles R., Ensign, United States Naval Reserve Force, U. S. S. Waukiva.
Segalowitz, Oscar, First Sergeant, Company D, 302nd Engineers.
Shea, Thomas F., First Class Private, Aviation Section S C.
Sheedy, M. M., Captain Engineers U. S. R., Company C, 21st Regiment Engineers (Light Railway).
Simmons, Harry M., Second Lieutenant, 6th Division Engineers, Field Train, U. S. A.
Smith, Robert W., Second Lieutenant, Engineer Officers' Reserve Corps, 106th Engineers.
Snavely, A. Bowman, Second Lieutenant, Coast Artillery, Officers Reserve Corps, Fort Dupont, Del.
Spaulding, H. C., Captain, U. S. R., Purchase Section, Gun Division, Ordnance Department.
Spencer, C. G., First Lieutenant, Aviation Section, Signal Officers' Reserve Corps.
Spencer, F. G., Captain, Ordnance Department, U. S. R.
Stem, Clifford H., Second Lieutenant, Engineers, U. S. R.
Stewart, Harry M., Sergeant Motor Truck 375, Motor Supply Train 409, Quartermasters' Corps, U. S. A.
Sticksel, C. P., First Lieutenant, Engineer Reserve Corps.
Stringham, Joseph S., Captain, Ordnance Department, Rock Island, Arsenal, Ill.
Swain, Philip W., Second Lieutenant, Field Artillery Reserve Corps, B Battery, 303rd Field Artillery.
Swetting, J. Rodney, Second Lieutenant, Engineer Officers' Reserve Corps.

Talbot, John Alden, Second Lieutenant, Field Artillery, United States Reserve.
Tangeman, W. W., Lieutenant, United States Army.
Terry, M. V., Captain, Engineer Officers' Reserve Corps.
Thomas, Felix, First Lieutenant, Motor Equipment Section, Ordnance Department, Carriage Division, U. S. R.
Thomas, Winthrop G., Corporal, Depot Company H, Signal Corps, United States Army.
Thompson, Paul W., First Lieutenant, Ordnance Department, Gun Division.
Tompkins, Harold D., Lieutenant, Company C, 104th Field Signal Battalion, Camp McClellan, Ala.
Turner, Channing, First Lieutenant, Field Artillery, Officers' Reserve Corps.
Tuska, Gustave R., Major, Engineer Officers' Reserve Corps.

Van Denburgh, O. A., Jr., Private, Enlisted Ordnance Corps, National Army.
Vinnedge, Earle W., Second Lieutenant, Engineers U. S. R., American Expeditionary Forces.

Wahl, James H., Lieutenant (Junior Grade), United States Naval Reserve Force.
Walker, L. E., First Lieutenant, Ordnance Department, Production Section, Carriage Division, U. S. R.
Wall, George L., Major, Ordnance Reserve Corps.
Walsh, Walter V., Aviation Section, Signal Corps, U. S. Army.
Waters, Everett O., Second Lieutenant, Ordnance Section, Officers' Reserve Corps.
Wells, A. E., Major, 121st Infantry, U. S. A.
Whyte, Jessel S., Captain, Company F, 310th Engineers, United States Army.
Williams, H. E., Captain, Field Artillery, Officers' Reserve Corps.
Williams, Harold J., First Lieutenant, Ordnance Department, United States Reserve, Carriage Division, Field Artillery Section.
Williams, Samuel S., Aviation Section, Signal Reserve Corps.
Woodcock, William E., Second Lieutenant, Engineers, United States Reserve.
Woodward, Hiram W., Second Lieutenant, 106th Engineers, U. S. R.
Woolson, Clifford G., Captain, Company A, 104th Engineers, S. E. Department, 29th Division, United States Army.
Wright, Stanley, Second Lieutenant, 314th Engineers, Camp Funston, Kan.

Young, John P., Fifth Company, Coast Artillery Corps, U. S. A., Fort Hancock, N. J.

NECROLOGY

E. W. GRIEVES

E. W. Grieves was born in Delaware in 1843 and attended the public schools in that state. He spent a four years' apprenticeship at woodworking, and then served several years as a patternmaker on ship and car work and as a designer and constructor of cars.

He became the chief draftsman and assistant superintendent of the shops of the Harlan & Hollingsworth Co. Later he was associated with the Baltimore and Ohio Railroad as master car builder. At the time of his death he held the position of mechanical expert with the Galena Signal Oil Co., Franklin, Pa.

Mr. Grieves became a member of the Society in 1891. He died in February 1917.

E. W. GRIEVES

CHARLES E. NEWTON

Charles E. Newton was born in Hartford, Conn., in 1858. He was educated in the public schools of that city, leaving high school to enter the employ of the Jewell Belting Co. in Hartford as office boy, where his ability speedily won him promotion. He became salesman for the company and was on the road for a number of years, where he had more than usual success.

In 1892 Mr. Newton was elected secretary of the company, and later became assistant manager. His responsibilities increased with time, and in August 1917 he became president of the company.

Mr. Newton became an Associate of the Society in 1895. He died on November 15, 1917.

HENRY RUTGERS FORD

Henry R. Ford was born on January 30, 1871, in Lawrenceville, Pa. He was educated in Binghamton, N. Y., attending both the grammar and high schools of that city. Later he took the engineering course at Pratt Institute, Brooklyn.

After serving his apprenticeship as electric wireman and as machinist, he obtained a position with the Edison Electric Illuminating Co., New York City, as wireman. In 1893 he was employed by the F. P. Little Company, Buffalo, N. Y., in the capacity of wireman and machinist, later becoming foreman and superintendent. In 1898 Mr. Ford became associated with the firm of McCarthy Bros. & Ford, giving special attention to designing, general engineering and contract work. Throughout Buffalo and its vicinity he designed and installed many steam- and gas-power and lighting plants.

He became a member of the Society in 1914. He died on October 31, 1917.

JOSEPH REID

Joseph Reid was born on November 11, 1843, in Maybole, Ayrshire, Scotland, where he attended the public schools until his eleventh year. He then was apprenticed by his father to learn the joiners' trade, at which he worked for four years. Later he became a machinist in the railroad shops of the Glasgow and Southwestern Railroad Co., Kilmarnock, Scotland.

In 1863 Mr. Reid located in Montreal, Canada, where he worked for a short time as machinist, after which he followed his trade in the United States, and was for some years connected with the

JOSEPH REID

HENRY R. FORD

Baldwin Locomotive Works in Philadelphia. In 1876 he entered the service of the Atlantic and Great Western Railroad Co., now the Erie Railroad, at Meadville, Pa.

In the following year Mr. Reid went to Oil City, where he worked with W. J. Innis & Co. and also with the firm of Malcomson & Patterson. When the latter firm failed in business, he bought their shop and started a small business of his own. In addition to general jobbing work, he made a specialty of refinery supplies. The opening of the Lima, Ohio, oil fields found the refiners unable to take care of the grade of oil produced in that field. The oil, how-

ever, could be used as fuel, and after careful experiment Mr. Reid designed, patented and manufactured a line of oil burners which were very successful and to handle which in 1885 he formed the Reid Burner Co.

As the result of extensive experiment, Mr. Reid brought out in 1894 what is believed to have been the first practical natural-gas engine, and by 1899 had made many improvements in it. The small repair shop became a large factory and the Joseph Reid Gas Engine Co. was organized with Mr. Reid as president. Mr. Reid assisted also in organizing the Frick-Reid Supply Co., a large oil concern in the West, and was vice-president and director of this company. He was also president of the Reid Land & Development Co., which operates fruit ranches in the West.

Mr. Reid became a member of the Society in 1904. He died on October 23, 1917.

ROWLAND SPENCER BROTHERHOOD

Rowland S. Brotherhood was born in September 1875 in Charleston, S. C. He was educated at the Patric Military Institute, Anderson, S. C.

His apprenticeship was spent with the Betts Machine Co., Wilmington, Del., where he gained his experience in machine-tool designing. In 1902 he accepted a position with the Bethlehem Steel Tool Co., South Bethlehm, Pa., in hydraulic-press and machine-tool designing and on general mill work in charge of the manufacturing drawing office. In 1903 he resigned from this position to become associated with the Portland Iron & Steel Co., South Portland, Me., in general engineering and construction work during the erection of the plant. In 1904 he became connected with the Standard Horse Shoe Co., South Watertown, Mass., as a designer of horse-shoe bending and swedging machines. Later in the same year he took charge of the Brotherhood Railway Supply Co., and the following year accepted a position with the Cambria Steel Co., Johnstown, Pa., in the drafting department on boiler, engine, marine and locomotive work and designing special machinery.

In 1907 Mr. Brotherhood became connected with the Remington Arms-Union Metallic Cartridge Co., Bridgeport, Conn. His position was in the equipment department, where he designed automatic machinery and was assistant to the chief equipment engineer. After five years he resigned to accept a position with the International Silver Co., Bridgeport, superintending the changing of the entire plant over from steam to electric drive, the installation of a new electric-lighting system and the erection of a new building. From April 1913 until the time of his death Mr. Brotherhood's work dealt with the general mechanical, electrical and efficiency engineering of the company.

Mr. Brotherhood became a member of the Society in 1916. He was the secretary of the Meriden branch of the Connecticut Section. He died on October 13, 1917.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER FEBRUARY 10

A TOTAL of 157 new applications for membership in the Society are published in the first list of the new year. This makes 1766 new applications since January 1, 1917. The total membership of the Society is now upward of 8500.

Below is the list of candidates who have filed applications since the date of the last issue of The Journal. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate or Associate-Member, those in the third class under Associate-Member or Junior, and those in the fourth under Junior grade only. Applications for change of grading are also posted.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by February 10, and providing satisfactory replies have been received from the required number of references, they will be balloted upon by the Council. Those elected will be notified about March 15.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be slower than under normal conditions.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

California

ELLINGWOOD, E. L., Consulting Mechanical Engineer, National Bank Building, Los Angeles

HALLORAN, Ralph A., Gas Engineer, Standard Oil Co. of California Whittier

RINGE, William H., Pacific Coast Manager, Shepard Electric Crane & Hoist Co., of Montour Falls, N. Y., San Francisco

WHATLEY, Arthur C., Mechanical Engineer, Interstate Commerce Commission, San Francisco

Connecticut

BAYRER, L. Garfield, Production Superintendent, Billings & Spencer Co., Hartford

DEE, William V., Secretary, G. Drouve Co., Bridgeport

GLEDHILL, Ernest, Foreman Department Metals, The Remington Arms U. M. C. Co., Inc., Bridgeport

STANLEY, John C., President and General Manager, American & Bristol Manufacturing Co., Bridgeport

District of Columbia

GROVE, William G., Aeronautical Engineer, Balloon Section, Air Division, Signal Corps, U. S. Army, Washington

Florida

AHERN, J. F., Manager, Fairbanks-Morse & Co., Jacksonville

Idaho

GOUGH, Achilles C., Professor Industrial Arts and Engineering, Idaho Technical Institute, Pocatello

Illinois

BUTCHER, Ira A., General Superintendent, A. W. Stoolman, Champaign

DUDLEY, Edward F., Mechanical Engineer and Designer, Miehle Printing Press & Manufacturing Co., Chicago

GRIFFIN, Lorne A., Vice-President, American Steam Conveyor Corporation, Chicago

LEVY, Lehman, Mechanical Engineer, Wilson & Co., Chicago

LIBBY, Edwin S., Assistant Professor Experimental Engineering, Armour Institute of Technology, Chicago

WOODMAN, Andrew W., President, The Joliet Bridge & Iron Co., Chicago

Indiana

KJELDGAARD, Niels C. S., Engineer, Burnoil Engine Co., South Bend

MAYO, Edward H., Consulting Engineer, Fletcher Trust Building, Indianapolis

Iowa

HENNESSY, William J., Inspector of Engines and Boilers, Emergency Fleet Corporation, U. S. Shipping Board, Burlington

Kansas

PHELPS, Barton P., Engineer Shop Extensions, Santa Fé Railway System, Topeka

Maryland

DANA, William J., Instructor in Mechanical Engineering, Johns Hopkins University, Baltimore

WILKINSON, Turner A., Sales Manager, Erie City Iron Works, Baltimore

Massachusetts

BRADY, John J., Sales Agent, Boston Office, Heine Safety Boiler Co., Boston

DANA, Clarence A., Chief Draftsman, Lowell Division, Saco-Lowell Shops, Lowell

DERBYSHIRE, FREDERICK W., Manufacturer of Watch Tools, F. W. Derbyshire, Waltham
INGHAM, IRVING L., Chief Inspector, Gilbert & Barker Manufacturing Co., West Springfield
POLLOCK, ROBERT T., President, Robert T. Pollock Co., Boston

Michigan

CLUNE, JOSEPH P., Manager, Soda Ash Department, Solvay Process Co., Detroit
COLE, ROY E., Chief Engineer, Liberty Motor Car Co., Detroit
FIGEE, J. HENDRIK, Engineer, Steere Engineering Co., Detroit
HAZLEY, JOSEPH H., Sales Engineer, Wilmarth & Morman Co., Grand Rapids
WERNICKE, OTTO H. L., President, Wernicke Hatcher Pump Co., Grand Rapids

Minnesota

ROWLEY, FRANK B., Assistant Professor Experimental Engineering, University of Minnesota, Minneapolis

Missouri

DUFFY, RALPH E., Engineer, Public Service Commission of Missouri, Jefferson City
HEDRICK, EARLE R., Professor of Mathematics, The University of Missouri, Columbia
HOFF, JOHN A., Consulting Engineer, Anheuser-Busch Brewing Association, St. Louis

Nebraska

MITCHELL, WILLIAM A., Assistant Chief Engineer, The Great Western Sugar Co., Scottsbluff
SEATON, LAURENCE F., Professor of Mechanical Engineering, University of Nebraska, Lincoln

Nevada

MUNROE, HAROLD S., General Superintendent, Consolidated Coppermines Co., Kimberly

New Jersey

BEAVERS, GEORGE, JR., Works Manager, American Standard Metal Products Corporation, Paulsboro
COEY, STEWART C., Works Superintendent, The Celluloid Co., Newark
PALM, ROBERT, Chief Engineer, Chrome Steel Works, Chrome

New York

ABRAMS, JACK, Jack Abrams & Bro., Inc., Plumbing & Heating Contractors, New York
BETHELL, JAMES G., Patent Attorney, New York
BRIGHTMAN, HENRY M., General Manager, Interests of J. H. Flagler, New York
DAVIS, FRANCIS G., Master Mechanic, American Brass Co., Buffalo
DOWD, ALBERT A., Consulting Engineer, Russo-Baltic Car Works New York
DUNLAP, JOHN R., Editor and Publisher, *Industrial Management*, New York
ESHELMAN, CLARENCE M., Service Engineer, Cameron Machine Co., Brooklyn
FARNHAM, BION B., Superintendent Farnham Mfg. Co., Buffalo
FASTING, SVERRE, Contracting Engineer, Shepard Electric Crane & Hoist Co., Montour Falls
FRASER, JOHN, Consulting Engineer, New York
FULLER, FREDERICK M., Assistant Chief Engineer, Ice Machine Division, De La Vergne Machine Co., New York
GIRTANNER, ALEXANDER, Vice-President, American Steam Conveyor Corporation, New York
GRADY, JAMES J., President and Treasurer, Freeman & Grady, Inc., New York
GUNDLACH, CARL E., Chief Engineer, George Schautz Engineering Co., Inc., Buffalo
LEUDEMANN, JOHN, Chief Engineer and Superintendent, International Exhibit Building, New York
LIPETZ, ALPHONS I., Chief, Locomotive Department, Russian Mission of Ways of Communication, New York
McMILLAN, CHARLES E., Consulting and Inspection, Brazil Railway, New York
MEAGHER, FRANCIS J., Sales Engineer, W. F. Davis Machine Tool Co., New York
MOSCHETTI, RICHARD L., Mechanical Draftsman, Public Works Department, Navy Yard, New York
OHNSTRAND, ENOCH, Chief Engineer of Construction, Library Bureau, Ilion
PLAIN, MORSE D., Power Engineer, Syracuse Lighting Co., Syracuse
ROBBINS, GERALD G., Chief Draftsman, Shepard Electric Crane & Hoist Co., Montour Falls
SCHWEIGERT, WILLIAM F., Traveler, Niagara Machine & Tool Works, Buffalo
SEAMAN, FRANK W., Chief Engineer, Edward R. Ladew Co., Glen Cove
SELDEN, WILLIAM H., Chief Estimator, American Car & Foundry Co., New York

Ohio

BJOERN-CALLESEN, WILLIAM, Chief Draftsman, Development Department, Firestone Tire & Rubber Co., Akron
DAVISON, CHARLES M., Assistant Engineer, The Edwards Manufacturing Co., Cincinnati
DYKSTRA, JOHN E., Superintendent, Foos Gas Engine Co., Springfield
EVANS, FREDERICK H., Dean, College of Industrial Science of Toledo University, Toledo
UNVERFERTH, CLARENCE B. D., Chief Draftsman and Surveyor, County Surveyor's Office, New Court House, Dayton

Oklahoma

LANEY, LEON K., with Jordan, Laney & Nickel, Bartlesville
PETERSON, FRANKLIN P., Petroleum (Gas) Engineer, Frank P. Peterson & Co., Tulsa

Pennsylvania

De LAPOTTERIE, Harry, Works Manager, Townsend Co., Vice-President Metal Patents Co., New Brighton
GUCKER, FRANK T., Secretary and Treasurer, The John T. Dyer Quarry Co., Philadelphia
JONES, ALFRED, Superintendent, Armstrong Cork Co., Linoleum Department, Lancaster
LEECH, EDWARD, Construction Engineer, Barrett Co., Frankford
McKENNA, ROY C., President, Vanadium-Alloys Steel Co., Latrobe
WASILKOWSKI, FELIX J., Mechanical Engineer, David Lupton Sons Co., Philadelphia
WERTHEIM, FERD E., Production Engineer, Bonney Vise & Tool Works, Inc., Allentown

Rhode Island

GUILLEMETTE, JOSEPH D., Assistant Engineer, Warren B. Lewis, Providence

Tennessee

BEUTNER, VICTOR, Consulting Engineer, Knoxville

Wisconsin

JOHNS, EDWARD F., Assistant Engineer, Bayley Manufacturing Co., Milwaukee

Canada

DENTON, LOUIS L., Light, Heat & Power Engineer, Canadian Explosives, Ltd., Montreal
McCOY, LLOYD, Engineer on Special Work, Canadian Car & Foundry Co., Montreal
WARK, THOMAS A., General Superintendent, St. Maurice Paper Co., Cap Madeleine, P. Q.

Philippine Islands

SUZARA, AUGUSTUS, Boiler Inspector, Bureau of Customs, Philippine Government, Manila

Russia

JANOUSHEVSKY, PAUL, Chief Engineer Motive Power, Vladicaucase Railway, Petrograd

FOR CONSIDERATION AS ASSOCIATE OR ASSOCIATE-MEMBER

California

FAKKEMA, R., Draftsman, Holt Manufacturing Co., Stockton

Connecticut

STUART, CHARLES J., Mechanical Engineer, Footwear Division, U. S. Rubber Co., Naugatuck

Massachusetts

COYLE, WILLIAM T., Secretary and Mechanical Engineer, Deane Machine Co., Fitchburg

New Jersey

COUCH, FREDERICK F., Assistant Professor Mechanical Engineering, Rutgers College, New Brunswick

New York

BUTLER, RICHARD E., Engineer, The Babcock & Wilcox Co., New York

North Carolina

HEISKANEN, JALMAR E., Mechanical Engineer, The Champion Fibre Co., Canton

Virginia

LANCE, CLARENCE C., Shop Engineer, Seaboard Air Line Railway Co., Portsmouth

Dominican Republic

TRUEBA-SUAREZ, BENIGNO, Contracting Engineer, Erecting Sugar Factory, Central Las Pajas, Macoriz Sugar Co., San Pedor de Macoriz

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

California

KNAUER, HENRY S., Assistant Engineer of Tests and Chief Draftsman, Southern Pacific Co., Los Angeles

Connecticut

HERRICK, EDSON P., Cost Accountant, Colt's Patent Fire Arms Mfg. Co., Hartford
MacBEAN, ROBERT A., Industrial Engineering Staff, Winchester Repeating Arms Co., New Haven

District of Columbia

YOUNG, ROSS H., Squad Chief, Mechanical Designer, Stone & Webster Co., Washington

Illinois

MEYER, LESLIE C., Mechanical Engineer W. A. Jones Foundry & Machine Co., Chicago

Iowa

WILDER, MORRIS B., Industrial Engineer, Sioux City Gas & Electric Co., Sioux City

Massachusetts

GABELER, William H., Assistant Superintendent, Barrett Co., Everett

HORTON, William G., Turbine Tester, General Electric Co., Lynn

KING, Harry H., Mechanical Engineer, Scovell, Wellington & Co., Boston

New Jersey

GREGG, Louis D., Vice-President, The Gregg Co., Ltd., Hackensack

New York

BEVIN, Victor D., Shop Superintendent, United Filters Corp., Brooklyn

EVERITT, Commercial Engineering Department, New York Telephone Co., New York

JAMISON, George S., Engineer, Underwriters' Bureau of the Middle & Southern States, New York

Pennsylvania

TADDIKEN, Ulrich A., Engineer, Condenser Department, Westinghouse Electric & Manufacturing Co., Pittsburgh

ZIMMERMAN, James J., Inspector and Expeditor, Engineering Equipment, Mechanical Engineering Dept., Cambria Steel Co., Johnstown

Texas

MURPHY, Eugene A., Instructor Technical Courses, U. S. Signal Corps, Ground Officers Training School, San Antonio

FOR CONSIDERATION AS JUNIOR

Alabama

MILLER, Lewis H., Mechanical Engineer, The Tennessee Coal Iron & R. R. Co., Birmingham

MULLER, Jacob F., Jr., Assistant Secretary, Assistant Treasurer, United Gas & Electric Engineering Corporation, Birmingham

California

KARSTENSEN, Alvin M., Tool, Die and Machine Designer, Bethlehem Shipbuilding Corporation, San Francisco

Colorado

HARRISON, Horace L., Draftsman, Dorr Co., Denver

LUNDQUIST, Joseph M., Assistant Chief Engineer, River Smelting & Refining Co., Florence

Connecticut

JONES, Vincent L., Assistant Engineer, New York, New Haven & Hartford R. R. Co., Cos Cob

TAFT, Edgar W., Statistical Engineer, Winchester Repeating Arms Co., New Haven

WARNER, Ralph M., 1st Lieutenant Ord. Department, U. S. R., Union Metallic Cartridge Co., Bridgeport

Delaware

HOMEWOOD, George M., Junior Mechanical Engineer, E. I. du Pont de Nemours & Co., Wilmington

District of Columbia

McCREA, Charles L., Ensign, U. S. N. R. F., Bureau of Ordnance, Navy Department, Washington

SANDMANN, William F., Aeronautical Mechanical Engineer, Signal Service at Large, Washington

Illinois

KAHN, I. F., Assistant, Turbine Department, General Electric Co., Chicago

REED, Melbourne O., Junior Engineer, Cooley & Marvin Co., Chicago

Indiana

CROOK, William R., Chief Designer & Superintendent of Factory Building, Aerothrust Engine Co., La Porte

Kansas

ROBERT, Jules H., Instructor, Department of Applied Mechanics and Machine Design, Kansas State Agricultural College, Manhattan

Maine

CHADBOURNE, John L., with Portable Steam Saw Mill, North Berwick

New Jersey

ANTOSCH, Walter, Engineer, Standard Aero Corporation, Elizabeth

BARRY, John L., Jr., Engineer, Standard Aero Corporation, Elizabeth

COLDWELL, Clarence B., Sales Engineer, Voorhees Rubber Manufacturing Co., Jersey City

SMITH, Harry R., Testing Engineer, Hyatt Roller Bearing Co., Newark

THIERINGER, Herman, Production Department, Babcock & Wilcox Co., Bayonne

New York

BROWNELL, Frederick J., Mechanical Designer, Western Electric Co., New York

BUCHHAGEN, Walter H., Experimental Engineer, J. P. Devine Co., Buffalo

EPPS, Frank A., Chief Mechanical Engineer, Foamite Fire Extinguisher Co., New York

HEIDE, George F., Field Engineer, Construction Div., Interboro Rapid Transit Co., New York

HOLDEN, Edward A., Assistant Engineer and Draftsman, The Engineer Co., New York

LANDT, James L., Assistant to Mechanical Engineer, Semet-Solvay Co., Syracuse

LAUTZ, Edward G., Mechanical Engineer, Assistant to the President, Niagara Machine & Tools Works, Buffalo

LOCKE, Charles A., Head of Mechanical and Electrical Detailing, E. F. Terry Manufacturing Co., New York

MERRILL, S. Clifford, 2nd Lieutenant, Ordnance Reserve Corps, U. S. R., c/o National Envelope Co., New York

PARKER, Karr, Chief Engineer, McCarthy Bros. & Ford, Buffalo

PRIDDY, Benjamin E., Assistant Service Manager, Cameron Machine Co., Brooklyn

SILBER, Alfred A., Draftsman, Perin & Marshall, New York

WEISS, Paul A. H., Assistant Engineer, Central Hudson Gas & Electric Co., Poughkeepsie

Ohio

PARKER, George C., Assistant Chief Draftsman, Cincinnati Ball Crank Co., Cincinnati

SINNIGE, Carl E., Engineer, Plant Engrg. Dept., The Lodge & Shipley Machine Tool Co., Cincinnati

Pennsylvania

BLUM, Mayer I., Mechanical Draftsman, Stone & Webster Engineering Corporation, Philadelphia

JENSEN, James A., Mechanical Engineer, Quaker City Iron Works, Philadelphia

SHUTT, James M., Designing Draftsman, Arthur Brock, Jr., Philadelphia

Rhode Island

OWEN, Richard L., Draftsman, Brown & Sharpe Manufacturing Co., Providence

South Carolina

SLOAN, Pearson H., Mill Engineer, J. E. Sarrine Co., Greenville

Virginia

THEE, Walter C., 2nd Lieutenant, Coast Artillery Corps, U. S. A., Fortress Monroe

China

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping anyone desiring engineering services. The Society acts only as a clearing house in these matters.

In forwarding applications, stamps should be enclosed for transmittal to advertisers; applications of non members should be accompanied by a letter of reference or introduction from a member, such reference letter to be filed with the Society.

GOVERNMENT REQUESTS

The Society has been asked to make suggestions of men for the following positions with the Government. Non-members possessing the necessary qualifications may avail themselves of these notices by enclosing with their reply a personal introduction to the Secretary.

STAFF OF FIFTY MEN for the equipment division of Signal Corps, in connection with contracts for motors and airplanes, to handle detail work of passing on material and labor costs and quantity of both material and labor entering into work. Must have good general education and sound judgment, technical, manufacturing and accounting experience, with personal qualities which will command confidence and respect; must be capable of taking general charge of work and acting as chief of Section when latter is absent. Approximately three men will be stationed at each factory who will report to Finance Department in Washington. Best man of each group will be commissioned and given charge of special work at each point. 2475(a).

TRAVELING LABOR INVESTIGATOR, analyst of labor costs and conditions to improve and unify labor problem among contractors. May be commissioned. 2475(b).

TRAVELING MATERIAL INVESTIGATOR, to help in reducing waste of material and capable of readily locating and pointing out excessive costs. May be commissioned. 2475(c).

SPECIAL TOOL AND FIXTURE INVESTIGATOR, to travel between plants and assist in saving expense by unification of tool, jig and fixture work, capable of assisting contractors to find outside capacity where necessary due to lack of capacity in their own plants, and capable of passing upon cost of work, for Finance Department. Will probably be commissioned. 2475(d).

THREE ASSISTANTS in main office at Washington, who will be commissioned and assume charge of intelligent compilation of reports sent in by field force. 2475(e).

It is desired to have all of the men recruited for this work above the conscription age, to insure the permanence of the organization.

DRAFTSMEN on heating and plumbing, to go to France. 2476.

1. LABORATORY INVESTIGATION and testing of airplane instruments. 2477.

2. MECHANICIAN on same. 2477.

3 RESEARCH ENGINEER in physics. 2477

DRAFTSMEN DETAILERS on ordnance. 2507.

HIGH GRADE MECHANICAL ENGINEER experienced in freight handling and conveying work, design and building local ports for munitions. Major's Commission. In U. S. 2527

CIVIL ENGINEER, designer of buildings and docks. Major's Commission. In U. S. 2528.

EXPERIENCED CONSTRUCTION MEN, power houses and coaling facilities. Major's Commission. In U. S. 2529.

POWER HOUSE DESIGN AND CONSTRUCTION MEN. Captain's commission Later appointment of one man in charge of completed ports. In U. S. 2530.

STATISTICAL ENGINEER AND ACCOUNTANT; as chief statistical and estimator for construction work in U. S. 2531.

POSITIONS AVAILABLE

PHYSICISTS, ENGINEERS, DESIGNERS AND DRAFTSMEN for work of research, development, and design related to problems of telephonic, telegraphic and radio communication which are matters of public importance, required by the Western Electric Company, Inc. Both temporary and permanent positions open. Apply by letter, not in person unless so specifically requested, to F. B. Jewett, Chief Engineer, 463 West Street, New York City. 2178-AA.

TECHNICAL GRADUATE having three or four years' practical experience in efficient operation of boilers and stokers wanted for position of traveling engineer. Exceptional opportunity for man with initiative and ability to become expert combustion and steam engineer. Work requires extensive traveling in connection with investigation of power plants throughout country. 2340-AA.

YOUNG ENGINEER to take up safety work in connection with plant in New England and to take general charge of building inspection. 2438 (a) AA.

CHIEF CHEMIST in connection with investigation work involved in manufacture of product. 2438 (b)-AA.

MECHANICAL SUPERINTENDENT. Must be competent to handle and direct construction, installation and maintenance of buildings, machinery and equipment, also power-plant operation. Jurisdiction will cover several plants. Only high-calibered men need apply. Outline fully past experience, age, salary, credentials. 2440-AA.

OPERATING ENGINEER for industrial plant. Must be technical graduate, have had practical operating experience in power plants and be capable of handling power proposition involving approximately 5000 boiler h.p. State age, experience in detail and salary expected. Location vicinity of Chicago. 2445-AA.

MECHANICAL ENGINEERS for permanent positions with established firm of consulting engineers. Young men, not liable to early army-draft call preferred, but age not necessarily deciding factor. No special technical experience necessary, but must have good technical education upon which to build. Good opportunity for men now in other lines, who wish to enter consulting field. Reply in own handwriting, stating education, experience, age, weight, height, nationality, and salary expected at start. Location New York City. 2446-AA.

ENGINEER AND DRAFTSMAN familiar with power-plant work and general piping. Good future for young man interested in general steam engineering in large manufacturing plant. Stage age, experience and salary expected. Location Philadelphia. 2448-AA.

EXECUTIVE POSITION in purchasing department of firm manufacturing tires and sundries. Location New England. 2457-AA.

EXPERIENCED DESIGNER on small machinery and tool work, with small and growing concern building machinery for canning industry. Location Maryland. 2458-AA.

YOUNG MECHANICAL ENGINEER who has not yet passed beyond the point of doing installation work of light machinery, and who may wish to develop in salesmanship. Location New York. 2461-AA.

PRODUCTION ENGINEER with practical experience in manufacturing line. Prefer man familiar with brass-foundry practice. as well as small parts for automobile manufacture. Location New Jersey. 2463-AA.

YOUNG ENGINEER for testing. State experience, references, and salary wanted. Location Pennsylvania. 2467-AA.

YOUNG GRADUATE in mechanical or electrical engineering for drafting and estimating work in connection with blast furnaces and mines. Location East Tennessee. 2468-AA.

ENGINEER WORKS MANAGER, experienced man in shop principles and management, good executive and capable handler of men. Location West Virginia. 2470 (a)-AA.

SUPERINTENDENT assistant to above, practical shop man. 2470 (b)-AA.

ASSISTANT MECHANICAL ENGINEER, to pass on mechanical features of design, as strength of bases, shafts, sizes of bearings for particular duty and similar questions. Location New Jersey. 2471-AA.

ENGINEER, experienced in steam-power-station design, operation and efficiency. Location New York City. 2472-AA.

ENGINEER, experienced in power-station construction, must be familiar with modern steam-power-station construction and operation. Location Ohio. 2473-AA.

GAS ENGINEER, experienced in small municipal gas plants, on construction, operation, and efficiency. Must be familiar with standard practice and system ordinarily in use. Location New York and Ohio, part time in each place. 2474-AA.

COLLEGE GRADUATES, ENGINEERS. Men out at least a year for general shop-engineering work with growing concern. Work leads to industrial management. State full particulars. 2478-AA.

MECHANICAL ENGINEER, technical graduate, one who has had experience in stoker business preferred and experienced in answering technical correspondence. Good opportunity for right man. Location Chicago. 2479-AA.

YOUNG A-1 TIME-STUDY MEN, connected directly with general manager's office, large rubber plant; only high-grade men with strong sense of proportion and natural ability need apply. Salary commensurate with achievement. Location Ohio. 2480-AA.

CHIEF DRAFTSMAN, qualified to handle position in connection with aeroplane designing, working under chief engineer. Location Cleveland. 2482 (a)-AA.

A-1 TOOL AND FIXTURE DESIGNERS. Location Cleveland. 2482 (b)-AA.

DRAFTSMEN to lay out and arrange equipment to get both efficient utilization of floor space and economical plant operation, have sufficient electrical knowledge to make drawings of electric light and power systems required by electricians. Only reliable, experienced, persons wanted. Excellent opportunity for advancement with possibility of being placed in charge of entire drafting room. Plant manufactures nitric, sulphuric and muriatic acids, barium products, aniline dyes, dry colors, printing and lithographic inks and supplies, paints and varnishes. Salary to start $1200. Location Ohio. 2487-AA.

CHIEF ENGINEER versed in refrigeration and producer-gas engines. Salary $2400 to $3000 a year. Location 50 miles from Baltimore. 2488 (a)-AA.

EXPERIENCED DESIGNER familiar with automatic machinery, adding machines, etc., must be capable of developing complete design from freehand sketches. Permanent position open with concern at present doing important government work. Salary to start $40 to $50. Location New York City. 2491-AA.

SWITCHBOARD OPERATORS who have had experience in large stations, preferably young men with good education who can quality for responsible positions in this line of work. Location Ohio. 2492 (b)-AA.

ENGINEERING EDITOR to take responsible charge of monthly periodical in automotive-engineering field. Should have broad engineering training. Man with experience on high-class technical periodical preferred. State salary, education and experience, and enclose samples (which will be returned) of technical articles written or prepared for publication. Location New York City. 2493-AA.

GRADUATE ENGINEER capable of learning part of business for large industrial company, with view to taking charge of department. Previous experience unnecessary, but ability and energy essential. Location New Jersey. 2495-AA.

ASSISTANT MANAGER for engineering department of Brooklyn concern. Man best fitted for position would be one having experience along general metal-manufacturing lines, especially machine-shop and sheet-metal-stamping work. American citizen only considered. Duties are to have active charge of making up plans and estimates for new work. 2496-AA.

SUPERINTENDENT for road-making-machinery plant, consisting of machine and erecting shops, boiler and forge shops, foundry and wood working shop. Want man who has made good in similar position, of real executive ability, organizer and one who can handle men with the necessary push to drive job along. Salary to start $2500. Location New York State. 2497-AA.

STEEL SALESMAN not subject to military draft wanted by old-established steel house for permanent position. Give experience and full details in first letter. Location New York City. 2499-AA.

PRACTICAL MAN to take charge of laboratory. Should possess qualifications of engineer of tests as well as being practical man to handle foundry problems. Location Illinois. 2500-AA.

DRAFTSMEN familiar with designing and detailing machinery for economical production of farming machinery, automobiles, and pumps. Experience on cotton-gin and oil-mill machinery desirable but not essential. Must have some knowledge of shop and foundry practice. Salary depends on man. Location Georgia. 2503-AA.

ASSISTANT SUPERINTENDENT for shop making hydraulic forgings for 6, 8 and 9½-in. howitzer shells. Must be hustler and have practical experience along mechanical lines and ability to handle men. Need not be experienced forge man. Compensation dependent upon ability. Location Middle West. 2509-AA.

MAN for boiler-room-efficiency work, where principal duties will be to make flue gas analyses, get coal and ash samples, inspect equipment, and observe all boiler-room operations, with view to making improvements Previous experience not required. Salary $90 to $100, with good opportunity for energetic man. Location Ohio. 2510-AA.

SALES ENGINEER OR MACHINERY SALESMAN with good technical training, able to develop sales end of business in American machinery in France, with headquarters in Paris. Knowledge of French preferred, but not necessary. Man of 30 to 45 preferred. Must have actual sales experience, preferably in following lines: machine tools, power-plant and electric equipment, including oil engines, road-making machinery, and mining machinery. Location New York City. 2511-AA.

MANUFACTURER of engineering specialties, large eastern firm, long established, desires young man not under 30, with technical education, good personality, and initiative. Knowledge of heating, ventilation, and power-plant engineering and installation practice essential. Excellent opportunity provided for development and promotion for right man. In letter give full particulars and experience and salary expected. Location New Jersey. 2512-AA.

HIGH-CLASS ENGINEER, with engineering, as well as executive ability, to take charge of engineering department. Man capable of looking after generation of power, particularly, but who will also have charge of plant maintenance, construction of new building, and, in general, supervision of machine departments. Location Ohio. 2513-AA.

EXPERIENCED MAN to take full charge of production problems of Connecticut concern; young man who has qualifications essential to handling problems of production with success. 2515-AA.

ASSISTANT SUPERINTENDENT for factory manufacturing fire-extinguisher equipment. Organization employing both men and women. Man slightly over draft age with several years' practical experience. Technical training preferred. Headquarters New York. Salary depends on man. 2516-AA.

INSPECTOR for factory manufacturing small brass parts. Man over draft age, capable of taking charge of department. Salary to start $30. Location New York City. 2519-AA.

DRAFTSMAN for work on wide range of designing machinery for roofing manufacture, conveying, foundations and plant layout. Location New Jersey. 2504-AA.

DRAFTSMAN, mechanical and electrical experience, and familiar with conveying machinery or designing of similar type of machinery. Location New York City. 2518-AA.

MEN AVAILABLE

MECHANICAL ENGINEER or SUPERINTENDENT. American with 14 years' practical and theoretical experience. Specialist in steam, air, gas, oil and water-engineering specialties. Machines, tools, fixtures and shop equipment, shop maintenance, efficiency, engineering testing and production engineer. Executive who can go into shop and do things. Successfully held positions involving above. At present employed. Salary $3000. A-1.

CONSTRUCTION SUPERINTENDENT. American, age 30. Technical-school graduate. In charge of large plant construction for last eight years, responsible for labor, ordering of materials, quality and progress of work. Desires responsible position with growing manufacturing company. A-2.

EXECUTIVE MECHANICAL ENGINEER, master mechanic, construction superintendent or chief draftsman. Member, technical graduate, married, aged 39, with several years' high-grade commercial experience and sixteen years' varied engineering experience in design construction and operation of manufacturing properties. Broad experience on material handling and power-transmission machinery, shop layouts, equipment and operation, with considerable experience in their construction. Can design, supervise, install, organize and produce in field of ordinary metal manufacturing, comprising pattern, foundry, forge, structural and machine-shop departments. Broad technical knowledge, energetic and industrious, executive and administrative ability. Available immediately. About $4000. Correspondence solicited. A-3.

PURCHASING ENGINEER OR EXECUTIVE. Graduate mechanical engineer, 30, married, clean cut, aggressive, and with capacity for work. Has moved up to position of purchasing engineer and general-office executive with young company doing million-dollar business. Wishes change in position, Michigan preferred. A-4.

ORDNANCE ENGINEER. Member with broad experience in design, construction and testing of machine, automatic, semi-automatic and rapid-fire guns, mounts, and ammunition of all kinds. A-5.

MECHANICAL ENGINEER, Columbia graduate, 1912, desires position as assistant to executive or consulting engineer. Broad general engineering experience, including industrial-plant layouts, machine design, inspection, construction, etc. Salary $1800. A-6.

MECHANICAL ENGINEER OR ASSISTANT TO EXECUTIVE. Member, 39, Cornell graduate, with advanced engineering degrees. Fifteen years' experience in estimating, designing, construction, development of processes, operations and office work, also considerable knowledge of munitions. Would like to change position and secure permanency if possible with some firm now engaged in war work. A-7.

CHIEF DRAFTSMAN OR ASSOCIATE CHIEF ENGINEER. Associate member, 28. Employed as chief draftsman of tube company. Desires change offering larger possibilities with future. Experienced in mechanical and structural engineering, also efficiency engineer, designing, estimating and erection. Complete tube plants, rod, wire, billet, skelp, rail and steel mills. Acid and zinc plants,

by product coke-oven plant. Steel mill buildings and bridge design. Best references, desires permanent position. Salary to start $200. A-8.

SUPERINTENDENT. Member, graduate, mechanical, 1904, large western university engineering school. Fifteen years' practical experience along mechanical lines, machine-shop practice, pattern making, foundry practical and efficient production methods. Thoroughly familiar with Taylor system of organization and bonus or piece-rate system of labor rates. Would invest. Location Chicago. A-9.

EXECUTIVE, assistant to executive or mechanical engineer. Cornell graduate, 36, 12 years' experience in positions covering chief executive, office management and works manager, operation, construction and experimental work. Experienced in combustion, steam and gas power, gas manufacture. At present employed. A-10.

MECHANICAL ENGINEER, technical graduate, desires position as assistant engineer or chief draftsman of machine company. At present employed as designer, estimator, and testing engineer. Experience includes testing, machine and structural design, office engineering, machine-shop and steel-foundry practice. Location Middle of Far West preferred. A-11.

CONSTRUCTION ENGINEER OR WORKS ENGINEER, member, technical graduate, 36. Fourteen years' experience, in charge of engineering department and assistant to construction engineer. Is thoroughly experienced in designing of blooming, billet, rod and strip mills, merchant mills, etc., also complete wire-mill plants. At present employed. A-12.

FRANCE, sales, investigational or executive services offered by American graduate, M.E., 37, formerly resident in France and speaking the language fluently, at present earning about $4000; but seeking position with better future prospects. Machine and erecting-shop, drafting and designing-room, as well as executive and sales experience in both building and mechanical fields. French and American references. A-13.

MECHANICAL ENGINEER, 33, 11 years' estimating, designing and shop experience on boilers, superheaters, stokers and oil burners; also with heating, ventilating and air conditioning, desires position as chief draftsman or assistant to chief engineer or manager of progressive concern, where conditions allow development of ability. Location New York or Brooklyn preferred. A-14.

MECHANICAL ENGINEER with 15 years' experience in the design of power plants, industrial plants, heating, ventilation, etc. Has had charge of men and shown executive ability. At present holds responsible position but has very little work to do. Willing to consider responsible and permanent position only. A-15.

ASSISTANT TO SUPERINTENDENT OR PLANT ENGINEER. Cornell graduate, American, 35, with 13 years' experience in engineering department of both manufacturing and metallurgical plants, desires position with prospects of permanency and advancement. A-16.

MECHANICAL ENGINEER, member, 39, American, 22 years' experience on automatic machinery, automatic press tools and deep drawing-press work, 12 years' experience in Connecticut brass shops. Shall soon finish seven year contract with present employers. Can design, supervise, organize or install new work as mentioned above. A-17.

MECHANICAL ENGINEER, associate member, 15 years' experience in consulting, designing, machine-shop, laboratory work, superintending coistruction and with general high-grade mechanical engineering experience desires position where economical developing ability of patents and research work is required. Prefer Middle West, South West or West. A-18.

DIESEL ENGINE EXPERT desires to communicate with some concern, having the capital and willing to go into development of Diesel-engine business. Advertiser, now employed, has had broad engineering experience and knowledge of how to obtain real efficiency. Communications to be confidential. A-19.

ENGINEER AND SUPERINTENDENT. Successful in manufacture of high-explosive shells and tools for machining, nosing and finishing shells. Will consider any proposition along these lines for patriotic and personal reasons. A-20.

HEATING AND VENTILATING ENGINEER, M.E. graduate, American, 36, married. Seven years' experience in heating and ventilating engineering, both design and construction, experience in refrigeration and other lines of engineering. Sober, energetic and ambitious. Has reached limit of advancement with present employers. Prefers position in charge of work as assistant to chief engineer. Salary $3000 to $3500. Available February 1, 1918. A-21.

CHIEF ENGINEER OR MECHANICAL SUPERINTENDENT under 40, with technical education and sixteen years' experience in design, construction, and equipment of industrial buildings and power plants, now with large corporation, desires connection where organization and executive ability combined with engineering experience will command fair salary. A-22.

MECHANICAL ENGINEER, Columbia graduate, 1902. Has served in railroad-motive-power department for number of years. Desires position as mechanical engineer or engineer of tests on railroad or in a line of business related to railroading. At present employed. Salary expected, $3000. A-23.

YOUNG MECHANICAL ENGINEER desires position as assistant general superintendent, production manager or superintendent of equipment of large plant or general manager of small plant. Has successfully held above positions and also worked in machine shop and drafting room. Capable executive, thoroughly practical, aggressive and of generous build. Has specialized on production work, having full charge of designing and building equipment to produce wide range of articles of wire, sheet metal, wood, paper, etc., also designed and installed equipment for processing, assembling, conveying and labor saving. Understands cost accounting, estimating, rate setting, time study and routing; 28 years old, with family. Exempt under federal draft. At present employed. Salary $3500 to $4000. Any location, prefer concern one of whose lines, at least, is of vital importance to Government at this time. A-24.

MANUFACTURING OR MECHANICAL EXECUTIVE. Age 44, at present holding position as superintendent. Desires to locate in Bridgeport, Conn. Experienced in machine shop practice, and in manufacture of hardware, guns and ammunition. A-25.

TECHNICAL GRADUATE in mechanical engineering, 33, married, experience in factory planning and construction, design of special equipment, power-plant installation and maintenance, as well as organization and management, desires to make connection in executive capacity with progressive industrial enterprise. Location immaterial. Complete record with references available. Minimum salary considered $3600. A-26.

MANUFACTURING EXECUTIVE, 33, married. Thorough mechanical and modern management experience in manufacturing of small machines and sheet-metal goods. Fifteen years' experience from apprentice, through tool-making, designing, foremanship, to position of management engineer with leading company for past 4 years. Practical, progressive, originating, and clean cut. Interested only in permanent position with greater opportunites with reliable company located in good home town. A-27.

EXECUTIVE OR ASSISTANT SUPERINTENDENT. Technical education, American, 36. Practical mechanic, familiar with design of special machinery, tools, jigs, fixtures, etc., for manufacturing duplicate parts on interchangeable system. Twelve years in drafting room, including chief draftsman; six years' shop experience, one as foreman. Salary $2000. Location preferred, Eastern States. A-28.

CHIEF ENGINEER OR MASTER MECHANIC, with thorough technical and practical experience, covering construction, operation and upkeep of steel plant, specialty metallurgical work, heating and melting furnaces. A-29.

SAFETY ENGINEER, six years' thorough technical and practical experience in this capacity, with large steel works in Pennsylvania. A-30.

METALLURGIST AND TESTING ENGINEER. Graduate mechanical engineer, 33, married, wishes to connect with reliable concern, whose product requires careful and thorough testing nid heat-treating of steels. Interested only in permanent position with good prospects. Seven years' experience in steel research work and heat-treating, successful in handling men. At present employed. A-31.

WORKS MANAGER OR GENERAL SUPERINTENDENT, desires connection with large plant, any product from automobiles to clocks; broad-gage, fully-trained executive; 36; experienced in plant layout, best shop practice, management control methods, systems and man training; successful in all jobs through production, design and control divisions; man whose vision is equal to possibilities of business and accustomed to make plans become facts. A-32.

YOUNG MAN of proven ability, 9 years' practical experience in consulting engineering, contracting, sales engineering and technical editorial field. Specialist in mechanical and electrical equipments for power plants and buildings. Maintenance supervision, investigation, design and layout. A-33.

SUPERINTENDENT, MECHANICAL ENGINEER, or MECHANICAL DRAFTSMAN. Experienced in plant layout detail work, small machine design, rolling-mill machinery, installation of machinery and high-tension electric service, motors, generators, transformers, etc. Executive ability, can handle men. Machine shop practice and well experienced in furnace construction, annealing and melting type. Consider any position of technical nature. Graduate of Manual Training School and University in Mechanical Engineering, eight-year course. A-34.

ENGINEERING SURVEY

A Review of Engineering Progress and Attainment in Mechanical Engineering and Related Fields, Including a Digest of Current Technical Periodicals and Selected Titles of Engineering Articles

War Service Boards

THE mobilization of the industries of the United States for war purposes—The War Service Conference—was brought about by the Chamber of Commerce of the United States at a meeting of the business men from all over the country held in Washington today. Addresses were made by W. S. Gifford, director of the Council of National Defense; Daniel Willard, chairman of the War Industries Board; Harry A. Garfield, Fuel Administrator; Geo. N. Peek, industrial representative of the War Industries Board, and others.

"It is not going to be any light task," Mr. Gifford said, "to completely organize industry in this country, but we think we are going to do it effectively, so that we may go ahead and have these new war-service committees of the Chamber tell the Government what can and what should be done. It is obvious that some industries are going to be more essential than others, but it would be foolhardy to think that the time will not come when the so-called less essential industries may not be needed."

Mr. Gifford spoke of the question of possible Government recognition of the War Service Committee.

"This is a Democratic formation of committees by the industries and not by the Government," he said.

A. C. Bedford, president of the Standard Oil Company, who has been chairman of the Council of National Defense Committee on Oil and Petroleum Products, told the committeemen of some of the difficulties his committee had experienced in endeavoring to aid in organizing the war.

"Nevertheless," he said, "we have not failed to supply any order which has been given to us either by our own or any foreign government."

Mr. Willard discussed the industrial end of the war. After saying that legislation by Congress will be necessary before the country can have a plan of one centralized control of purchasing, such as the British Ministry of Munitions, Mr. Willard said that because a ministry of munitions had been established in England, it does not follow that such a plan would be successful here. (*Journal of Commerce and Commercial Bulletin*, December 13, 1917, p. 3)

4500-Ton Concrete Ship for U. S.

Working in conjunction with the Bureau of Standards, the United States Shipping Board has decided to start the construction of a concrete ship. A representative of the bureau returned today from San Francisco and reported favorably on a concrete vessel of 4500 tons which had been built there. The experiment by the Shipping Board will probably be begun shortly in one of the Southern yards, most likely in Georgia.

Announcement was also made by the board today that a Boston concern would build a concrete vessel of 3500 tons at its own expense, which would be turned over to the Shipping Board. If satisfactory, this firm will be awarded a contract for twenty more ships of the same size and type. This vessel will be constructed in a yard nearby that where the Shipping Board will try its experiment.

Hope is held out that the concrete ships which will soon be laid down will prove practicable, as the material involved is not required for any other section of the war program, and could be obtained without difficulty. Only a small amount of steel is needed for concrete ships, which have another advantage in that they can be speedily constructed. The time for completing a concrete hull is estimated at sixty days at the most. The vessels are expected to be capable of a speed of ten knots or greater.

Secretary Redfield today requested the Shipping Board to coöperate so far as possible with the Bureau of Standards. An inspector will probably be appointed for the Pacific Coast, and also for the South, with this idea in view. The Shipping Board may make an appropriation specifically for this work. (*Journal of Commerce and Commercial Bulletin*, December 13, 1917, p. 5)

Naval Vessels in Commission

At the beginning of the fiscal year 1917, the monthly expenditures for all naval purposes were about \$8,000,000; they are now about \$60,000,000. On January 1, 1917, there were 300 naval vessels of all kinds in commission; today there are many more than a thousand. These typical figures sufficiently indicate the task the navy has had to accomplish to date in the way of expansion.

There was embarrassment in the early days of the war by reason of the patriotic and eager response of the young men of the country to the navy's efforts in recruiting. These were so successful that it was difficult with the then facilities to take care of the flood of volunteers. There were also various threats of epidemics of the diseases that appear when unseasoned men are suddenly assembled in large numbers. These, however, were stamped out, and facilities either completed or to be ready before winter are now adequate for the needs of the present navy personnel. If required, these can be enlarged even more rapidly after the experience now had. (*The Official Bulletin*, December 11, 1917, p. 10)

Concrete Craft May Operate on Canals

The *Barge Canal Bulletin* for November, which makes a rather belated appearance, contains a hint that concrete craft may be seen on the canals during the coming summer. A review of the situation reads in part:

"During the intervening winter, if sufficient energy is exerted, the new craft for this traffic may be built and the old boats be made more suitable, but there must be no delay in beginning. It may happen, also, that the season will witness an innovation in the kind of boat. Many studies in boat building have been made recently by various engineers and naval architects, and the vessel constructed of reinforced concrete has not been overlooked. This type has the advantage of quick construction, and of being composed of materials which can be obtained easily and without interfering greatly with ordinary war supplies." (*Journal of Commerce and Commercial Bulletin*, December 15, 1917, p. 16)

Change in Airplane Program

Recent rumors that the Liberty airplane engine had proved a failure are emphatically denied in official quarters in Washington. Unofficially, *The Iron Age* learns, however, that a decision has been reached to limit the use of the Liberty motor to scout duty and the time-tried French motors will be used on the battle airplanes used by the United States Government. In various ways the airplane plans of France and the United States appear to have been consolidated. " The French-American airplane program " is a phrase that is now frequently used in Washington.

The decision to use the Liberty motor for scout duty only is believed to have followed the criticism of French airplane experts that the United States in putting all its faith in the one motor was placing its eggs in one basket, and that if, under actual fighting conditions, the Liberty motor did not measure fully up to expectations, there would be nothing to fall back upon. The motors which the French and English have used most successfully in battle are the Renault, Gnome, Hispano-Suiza and the Rolls-Royce. It is now apparent that this Government will build a certain number of each of these motors in the United States. Contracts have recently been placed with American manufacturers for Renault and Hispano-Suiza motors and other contracts are pending. In addition, this Government will provide additional equipment for the French automobile plants which are making airplane engines and will also supply several thousand mechanics, who are now being recruited. The original program was to build only 5000 Liberty motors in France, but latest information is to be the effect that the United States will assist the French in building a large number of French and English engines as well.

An important step in the airplane program was the taking over by the Aircraft Production Board of the plant and equipment of the General Vehicle Co., Long Island City, N. Y., at a price said to have been fixed at $2,500,000. The General Vehicle Co. has been figuring for some time on a large contract for the manufacture of Gnome motors and had issued a list of about 900 machine tools to be purchased. The plant will probably be used by the Aircraft Production Board for experiments in airplane engine construction. (*The Iron Age*, vol. 100, no. 22, November 29, 1917, p. 1331)

National Advisory Committee for Aeronautics

The last annual report of the Executive Committee of the National Advisory Committee for Aeronautics gives many interesting data on the activities of the Committee during the fiscal year 1916-1917. Naturally, some of the activities can be mentioned in only a summary manner, but the report, nevertheless, first shows that a large volume of important work has been performed.

In March 1917 the committee arranged, in conjunction with the National Research Council for representation on the Foreign Committee sent abroad by the National Research Council, to obtain detailed information on scientific matters of importance in connection with the war. Dr. Joseph S. Ames was appointed as such representative.

In October 1916 the committee took under consideration the question of the selection of a suitable site for its proposed experimental laboratory. In this study the committee acted in coöperation with a board of officers of the U. S. Army which had been appointed to inspect sites for the experimental station and proving ground of the War Department.

At the suggestion of the War Department requesting recommendation by the Advisory Committee in the matter, this committee inspected several proposed sites, and after making inquiries as to the general health conditions and the problems of accessibility to Washington and the larger industrial centers of the East, protection from enemy naval attack, climatic conditions, and cost of the site, it made recommendation to the War Department for the purchase of a site about four miles north of Hampton, Va., which recommendation was accepted by the War Department, and the site was purchased.

On this field the War Department has allotted to the committee a space suited to the erection of the committee's proposed research laboratories. The committee has designed the first building of the group contemplated, and the design has been approved by the architects for the War Department. Contract has been entered into with the J. G. White Engineering Corporation, New York City, for the erection of the laboratory at an estimated cost of $80,900. The laboratory building is now in the course of construction. At this laboratory the committee will carry on, in wide variety, research and investigation relating to aeronautic science, and including a study of planes in free flight. The committee has also under preparation plans for the first aerodynamic laboratory to be installed at Langley Field intended for the development of high wind speeds. The work on this laboratory will be begun as plans are ready.

The committee has coöperated with the Aircraft Production Board in connection with a wide variety of problems relating to the design, specifications, and tests of aircraft. The committee has now in hand (November 1917) a most important investigation on the use of steel for airplane construction, and is supervising the development of a design for construction in steel, to be later subject to a program of tests intended to show the possibilities of such type of construction.

In connection with the subject of the materials for airplane construction, the committee has given its attention chiefly to the investigation of strut forms for airplanes, the strength of spruce spars, and the development of cotton airplane fabrics as a substitute for Irish linen.

In the field of power-plant design and construction for aircraft, the committee has coöperated with the Bureau of Standards in the design, construction, equipment and operation of a large vacuum-chamber, engine-testing laboratory which is intended to reproduce the conditions of aeronautic engines operating at high altitudes. This equipment has been installed with special reference to the development and improvement of the Liberty engine and important investigations bearing on this problem are now being carried forward. The committee has also carried on a number of researches on the subject of radiator design and proportions, carburetor design and adjustment, ignition apparatus, and is continuing its study of the problem of an airplane engine muffler.

At the request of the War Department, the committee loaned one of the members of its technical staff for the supervision of tests on the first Liberty engines at Detroit, Pike's Peak, and elsewhere, to determine their mechanical and thermal efficiency and the power delivery of the engines at various altitudes.

The committee has undertaken important investigations relating to the development of various instruments used in the navigation of aircraft and in testing aircraft in free flight. In particular there has been developed an improved form of geographic position indicator which will be of special value in connection with certain free-flight tests under consideration.

Regarding the subject of aircraft communications, the committee has coöperated in the development of a generator for wireless sending from airplanes and intended to satisfy the requirements of the army and navy. Means for receiving wireless signals in an airplane have also been investigated, and it has been established that a very efficient receiving set employing the sound method is practicable; investigations are still being carried on regarding means for detecting hostile airplanes before they are visible or before they can be heard by the unaided ear.

On March 8, 1917, the committee took under consideration the development of methods for mapping from airplanes which should be rapid, economical and sufficiently accurate for aviation purposes. Allotments were made for developing a new type of airplane mapping camera, and gratifying progress has been made in the development of such an instrument. Before regular navigation of the air can be undertaken, it will be necessary to supply maps and to establish and suitably mark aerial routes and suitable landing places for the aviator. In certain sections of the country and through the generous coöperation of patriotic citizens interested in this work, gratifying progress has been made in these directions, notably between Dayton, Ohio, and Rantoul, Ill.

Soon after the declaration of hostilities with Germany, the Chief Signal Officer called to the attention of the committee the large amount of material which was coming before the War Department, comprising inventions and suggestions relating to aeronautics in warfare, and asked assistance in examining and disposing of such material. Accordingly, this committee, through an appropriate sub-committee appointed for the purpose, has acted as a board of inventions for the Government in matters relating to aeronautics, and since the outbreak of hostilities between the United States and Germany it has weekly examined hundreds of suggestions and inventions pertaining to this subject, and referred to it by the War and Navy Departments, in addition to the suggestions and inventions which come direct to the committee. This work has required a large amount of time and careful study, and has called for considerable increase in the technical and clerical staff of the committee in order to care for the very large amount of examinations, study, and correspondence with inventors regarding these matters. Several suggestions of value have been received and brought promptly to the attention of the particular Government office that was most directly interested.

During the year the committee has given further attention to the subject of the definition and standardization of technical terms used in aeronautics, and has prepared a further edition of its bulletin on the subject (Technical Report No. 15).

On recommendation of the Advisory Committee, in December 1916, the War, Treasury, Interior and Commerce Departments adopted the metric system of weights and measures for all drawings and calculations on aeronautical matters, for use with the accompanying English equivalents.

The committee has made progress during the year in the study and investigation of the following problems:

Stability as determined by mathematical investigation
Air speed meters
Wind sections
Aeronautical-engine design
Radiator design
Air-propeller design and efficiency
Forms of airplane
Radiotelegraphy
Non-corrosive materials
Flat and cambered surfaces
Terminal connections
Characteristics of constructive materials
Standardization of specifications for materials.

First Machine-Made Liberty Engine

The first machine-made Liberty airplane engine was completed on Thanksgiving Day and a substantial number will be delivered this month. Production of Liberty airplane engines on a quantity basis has actually begun, while at the same time aviators are being graduated in large numbers from training schools here to immediately travel to the fighting lines in Europe. It may be authoritatively stated that the United States is within sight of realization of the great air-fleet project mapped out since the date this country entered the war.

Figures cannot be published for obvious reasons, but it became known in Washington, following the return of members of the Aircraft Board from an inspection trip through the country, that these members are certain that another 60 days will witness men and machines being turned out at a rate insuring success to the original plans. Numerous tests have been made for power, gasoline consumption and for breakdown, and these have proven the engines to be even more powerful and efficient than was originally claimed for them. (*Automotive Industries*, vol. 37, no. 24, December 13, 1917, p. 1064).

Exchange of Technical Information with the Allies

There has been a particularly frank and free interchange of naval and technical information between the countries with which we are allied and ourselves which has been of great value in view of actual war experiences abroad. Not only as to broad policies, but also with respect to details of construction and tactics we are in close touch. The "partnership of democratic nations" has thus already proved its efficacy in the conduct of naval war.

While the details of what have been done, and how we have done it, must wait until it is permissible to spread them upon public record, this summary may be given to our people: In the navy we have prepared for and have met the duties of the present; we are preparing for and are confident we will be able to meet any call for greater duties, for more exacting responsibilities. The best way to secure enduring peace is to prepare unceasingly, night and day, for the winning of the war. (From the annual report of the Secretary of the Navy, see *The Official Bulletin*, December 11, 1917, p. 11)

Burn More Wood, Save Coal, Fuel Administration Urges

The Fuel Administration issues the following:

"The United States Fuel Administration, in coöperation with the Department of Agriculture, has inaugurated an intensive campaign for the substitution of wood for coal. The action is taken as a means of conserving the coal supply.

"In this connection it is announced that the Department of Agriculture will provide the services of expert foresters, who will supervise cutting of wood so that no damage may be done to growing timber, and that the largest use may be obtained of the supply of wood.

"One cord of hardwood is equal to a ton of coal, according

to the experts of the Fuel Administration. The Department of Agriculture and the Fuel Administration have statistics showing that there is a vast quantity of dead wood in many sections of the country, and that the supply in many communities is sufficient for domestic purposes. This wood, in many instances, is destroyed as waste." (*Official Bulletin*, November 30, 1917, p. 5)

Enlistment of Students in the Technical Schools

The Provost Marshal General has sent the following telegram to the governors of all states:

"Section 151, Selective Service Regulations is amended by the addition of sub-paragraph D as follows:

"Under such regulations as the Chief of Engineers may prescribe, a proportion of the students, as named by the school faculty, pursuing an engineering course in one of the approved technical engineering schools listed in the War Department, may enlist in the Enlisted Reserve Corps of the Engineer Department, and thereafter, upon presentation by the registrant to his local board of a certificate of enlistment, such certificate shall be filed with the questionnaire, and the registrant shall be placed in Class 5 on the ground that he is in the military service of the United States." (*Official Bulletin*, December 11, 1917, p. 4)

U. S. BUREAU OF STANDARDS

In the investigation of building stones of the United States now being conducted at the Bureau of Standards, the tests of sandstones have been completed and work begun on the Indiana limestones with a view to grading as to quality and use. The special experimental freezing apparatus for testing the stone has been installed and is now ready to put into operation.

Stresses on Floors. Investigation is being made of working stresses and loads on floors built under the regulations of the Baltimore Code as compared with floors built under Government regulations. Preparations have been completed for the testing of three floors for the Bureau of Yards and Docks, Navy Department. These tests are to be made on concrete floors in warehouses located at New London, Conn., Charleston, S. C., and Hampton Roads, Va. It is anticipated that these tests will be made within the next few weeks. The results will afford an excellent opportunity for the investigation of flat-slab floor design, as the floors in question are designed by three different systems to carry the same live load.

Cement Testing. The amount of cement testing done by the Bureau of Standards has increased 800 per cent during the past month over the corresponding period twelve months ago.

Steel Wheels for Motor Trucks. A number of truck wheels were tested for the War Department, covering different makes of wheels. The wheels were submitted in pairs, each including a front and a rear wheel. The testing was done in a large 3,200,000-lb. Emery testing machine.

Test of Stop Watches. The Bureau has carried out tests on 1200 stop watches to determine their accuracy with a view to acceptance on contracts. Runs of 30 sec., 1 min., and 5 min. were made on each watch and a tolerance of 0.4 sec. was allowed. Only 10 per cent of the watches failed to pass the test, some for defective mechanism and the majority for exceeding the tolerance.

Investigation on Cloth Tapes. A comparative test of sample cloth tapes was made to determine which would be most suitable for use in rough measurements such as the measurement of hulls of vessels of the Steamboat Inspection Service. This test included determination of the errors of the tapes; the change in length with tension; the recovery of length after tension had been applied; the effect of moisture on the tapes in their original condition when new, and the effect upon these factors of wear upon the tape. To ascertain the latter, the tapes were run by means of a motor and idler pulley over a series of obstructions covered with sandpaper that removed part of the coating in a manner similar to what would take place in use. One of the tapes was a so-called metallic tape having several threads of metal tinsel running lengthwise of the tape. The other was a linen tape without such threads. The latter tape showed greater changes in the first part of the test and its surface was worn off more in the latter part of the test, resulting in greater exposure to the efforts of moisture and consequent shrinkage of the tape.

Instruments and Methods. A new profile device is being constructed from two discarded theodolites and a "last-word indicator," and will give errors in profiles without computation, thus making a great saving in time. Another important feature is the method of adjusting profiles, which separates the adjustments necessary for proper alignment to two definite motions.

Short-Weight Mine Scales. Note may be made of the successful conclusion of cases against mining companies in Maryland, inaugurated by the Grand Jury of Allegheny County, as a result of disclosures made by the Bureau after a test of nine scales in this region. One company was fined $900 and costs. Sentence was withheld in another case until the conclusion of negotiations between the miners and the company regarding the payment of back wages which have accumulated as a result of short weighing of coal mined.

Infra-Red Spectroscopy. During November the work on infra-red photography was continued. Data were collected which will enable the absorption lines in the solar spectrum to be classified as solar or terrestrial. The latter are due to the selective absorption of the earth's atmosphere. The spectra of iron and cobalt have been extended well beyond 10,000 Angstrom units or 1 μ, and the nickel spectrum has been photographed to 9700 A. The measurements of iron and cobalt spectra have been collected and the data are ready for publication. A preliminary report on the solar work has been sent to press and will shortly be available. An important development of this work is its application to military photography.

Engineering Research. A large number of engineering problems are being investigated by the Bureau, among which some typical examples may be cited: design of airplane thrust and torque dynamometer, investigation of aluminum struts, magneto couplings, arc-welded sheets for lifeboat construction, design of instrument for measuring tension in airplane cables, machine-tool investigation, investigation of structural columns, and many other problems of military importance where the subjects are of confidential character.

NEWS OF OTHER SOCIETIES

Society of Naval Architects and Marine Engineers

LOYAL support of the Government in the present crisis was pledged by the Society of Naval Architects and Marine Engineers at its annual meeting held in New York, November 15 and 16, and at the same time in a petition to the President of the United States an earnest plea was made for the appointment of a representative builder of merchant vessels as a member of the Council of National Defense, where other important industries engaged in war work are now represented.

Throughout the meetings, and at the annual banquet which followed and was addressed by the Secretary of the Navy, the general manager of the United States Shipping Board Emergency Fleet Corporation and representative shipbuilders, the difficulties which shipbuilders are now facing, arising from the shortage of labor, labor troubles and the urgent need of increased production, were constantly referred to. Two of the papers presented at the technical meetings dealt with various phases of the labor problem. The first described the service department which has recently been established at the Fore River shipyard, and which has proved so successful that the underlying principles on which it is based are now being extended to all shipyards of the country through the Industrial Service Department of the Emergency Fleet Corporation. The other paper, by Naval Constructor T. G. Roberts, U. S. N., analyzed the principles of industrial management, especially as applied to the organization of a shipyard. Still another phase of the labor question as applied to the manning of the emergency fleet was discussed in a paper on the Progress of Marine Engineering and the Education of Marine Engineers.

The effect of the war on ship design and construction was reflected in at least three papers. The first described the method of building fabricated ships, as developed by the Chester Shipbuilding Company, Ltd., and the Merchant Shipbuilding Corporation. The second gave the results of tests at the Government experimental tank in Washington on models of cargo ships with lines of simple form, where the ordinary ship sections are replaced by straight-line sections with rounded bilges. The results of these experiments led the author, Naval Constructor William McIntee, U. S. N., to the conclusion that cargo vessels can be built on simplified lines which will give practically as good results from the resistance standpoint as those built on the present conventional lines. If propulsive efficiency is also taken into account, it is believed that the simplified form will have, at least in certain cases, advantages over the present type. The third paper, by Robert W. Morrell, hull superintendent of the Standard Oil Company of New Jersey, outlined recent developments in tank-steamer construction, showing that the total tonnage of American tankers now in service represents about 20 per cent of the total American steel-vessel tonnage, exclusive of that on the Great Lakes, as against 10 per cent at the beginning of 1915. Previous to 1915, the average size of the modern tanker was 5200 tons, while at present it has increased to 9100 tons. Along with the increased size has come the development of the shelter-deck type of vessel, and a growing tendency to adopt a straight sheer line amidships. Special constructional features which have recently been developed are the adoption of the rolled tee-bar section for oiltight work and the use of the multiple punch. In closing, Mr. Morrell points out that as all of the tank vessels now under construction are for 1917-1918 delivery, and as the Shipping Board has failed to provide for any tank-steamer construction in its shipbuilding program, the building of tank ships will soon be at a standstill in this country, in spite of the fact that the transportation of oil is one of the greatest necessities in the war.

The submarine question was taken up in two papers, one by Naval Constructor E. S. Land, U. S. N., which discussed the relative advantages and disadvantages of single- and double-hull types of submarines, and the other by Marley F. Hay, which outlined the influence of the war on submarine policy and advocated a new type of submarine, designated as a contra-submarine, especially designed for offensive warfare against submarines.

Several papers dealt with various auxiliaries on board ship, one by Dr. K. Suyehiro of Japan, describing an ingenious device for comparing the rotation of shafts; another by H. L. Hibbard, reviewing the applications of electricity to various auxiliaries on shipboard, and a third by Elmer A. Sperry, giving the results of the application of gyro stabilizers on board ship for the prevention of rolling. Valuable data were also given by W. W. Smith in a paper on Wind and Fouling Resistance on the Naval Collier *Neptune,* as determined both by model experiments in the Washington wind tunnel and from the service performance of the vessel, and by Messrs. A. G. Mattsson and Thomas Durkin, in a paper giving power and economy tests of one of the most efficient ore carriers on the Great Lakes.

H. H. Brown.

National Machine Tool Builders' Association

The Annual Meeting of the National Machine Tool Builders' Association was held at the Hotel Astor in New York on October 30-31.

The Machine Tool Builders' Association, composed, as it is, of the owners and the executive heads of machine-tool-building concerns, generally devotes its time more to the commercial than to the engineering side of the business. The session was marked by a very keen interest in present conditions. President J. B. Doan set the keynote in calling attention to the very important part that the machine-tool builders now play in the necessities of the Government. Followed, as this was, by a talk by Mr. Henry Japp, C. B. E., Deputy Director General in U. S. for British Minister of Munitions, the members and guests were still more impressed with the obligations resting upon them in the present crisis.

In an executive session, Mr. George E. Merryweather talked in a very intimate manner, and impressed by citation of actually existing conditions the necessity incumbent upon the machine-tool builder to urge forward work in this industry.

While there is no doubt but that the membership in all cases have been feeling the responsibility that is upon them at this time, yet this meeting impressed upon them more than ever that the greatest possible efforts that they could make would be needed to help improve conditions. Guns and ammunition are needed, and in large quantity, but before they can be produced to the extent that they should be, machine tools of nearly all types are wanted to produce them, and, as one speaker expressed it, while there might be a change in conditions later, today the machine-tool industry is the one that the manufacturers of all types are looking to to get out their production.

It is inspiring and helpful to participate in such a meeting

as this was—to see the response of men to the call when the necessities are visualized to them relative to their own businesses, and they respond with the purpose of doing not their "bit," but their whole.

The keynote of service that President Hollis struck at the time of installation into office last year, permeates not only the general engineering branches, but every branch of the service with which engineers and their co-workers have to do, and the complete printed report of this meeting, when it appears, will be well worth careful reading by all.

At the business meeting, J. B. Doan, of the American Tool Works Co., Cincinnati, was elected president.

W. A. VIALL.

Catalogue Studies

Through the courtesy of Mr. George Francis Whipple, the United Engineering Society Library has received a complete set of the Catalogue Studies compiled by him, together with a bookcase for the fifty-five volumes comprising the set at present.

This work represents an attempt on the part of some one hundred and fifty manufacturers of technical merchandise to make their catalogues more useful for reference purposes than such publications usually are. The machine catalogue of today is an expensive and valuable book, useful not only as a price list of the manufacturer's products, but also frequently as a manual of current practice, and for its tables of various constants, formulae, etc. Many catalogues are distinctly valuable as textbooks for educational purposes. Nowhere else are the latest approved methods so promptly available in print.

This material has, unfortunately, not been easily accessible in the past. This is partly due to the form in which it is published, partly to the difficulty of separating the useful material from that of little relevance, and partly to the lack of any key or index to that portion which is worth while.

To remove these difficulties has been the object of Mr. Whipple and the firms represented in this collection. The valuable catalogues issued by these firms have been selected and assembled in fifty-four binders of convenient sizes. An additional binder contains blueprints, charts, etc.

This Month's Abstracts

In the section Air Engineering a practical method is recommended for measuring air delivered by a turbo-blower; also the drop of pressure in compressed-air hose is discussed on the basis of tests carried out at the University of California.

An article on the hardening of aluminum bronze is indirectly abstracted from a German publication. It may be mentioned, in this connection, that with the exception of a few publications, mainly those concerned with aeronautics, marine engineering and internal-combustion engineering, there is at present no prohibition on the part of the German Government of the export of engineering publications. It has been stated, however, that the classes above referred to, as well as some of the medical and surgical periodicals, are not allowed to leave the country.

In the section Firing and Fuels is reproduced a chart prepared by Walter N. Polakov, Mem.Am.Soc.M.E., with which to make various records for coal.

Another article abstracted from *Power* deals with the control of smoking chimneys and describes a system of electric signaling by which an outside observer can call the attention of the firing squads to the fact that their stack is smoking. The subject of the flow in channels with large expansion ratio is abstracted in the section Hydraulics. The classification of this article is, however, somewhat uncertain, as it deals both with the flow of air and the flow of water.

In the section Machine Shop will be found brief answers given by various machine-tool builders showing their attitude toward motor drive. It is significant that the majority clearly recognize the value of motor drive, and that not a single company expresses its disapproval of this system.

A discussion of inspection of screw gages for munitions of war has been abstracted from a pamphlet published by H. J. Bingham-Powell, of the British Ministry of Munitions in the United States. We understand that this pamphlet is to be reprinted in part or in full in an early issue of the *American Machinist*.

In the same section attention is called to a brief list of specifications for munitions prepared by the Library of the Engineering Societies. While not claiming to be comprehensive, this list, it is believed, will prove of interest.

The refrigerator cars of the Baltimore & Ohio Railroad, described and illustrated in the section Railroad Engineering, are of interest in that the system of insulation is materially different from the usual practice. The bulkheads of the ice chambers are also made in a novel way.

In the same section, Railroad Engineering, an editorial has been abstracted from the *Railway Review* concerning standardization vs. improvement. The entrance of the United States into the war suddenly necessitating the production of vast quantities of direct and indirect war material largely in shops not designed to handle the particular class of material required, led the various boards to the adoption of a rather intensive system of standardization. This, in its turn, prompted an effort to extend standardization to fields where it was but sparingly known before. As shown by the editorial abstracted and by the account of the meeting of the Aeronautical Society of America, also in this issue, this tendency is beginning to meet opposition from various quarters. It may be of interest in this connection to recall that Sir David Henderson, formerly in charge of aircraft production in Great Britain, has also publicly cautioned this country against excessive standardization.

In the section Steam Engineering are two articles—one on nozzle characteristics and the other on purifying circulating water for surface condensers—which were indirectly abstracted from German publications.

Cleaning condenser tubes in place with hydrochloric acid, as practiced in South Africa, is described and illustrated. It appears that this method gives good results, but is rather expensive unless the acid can be secured at very low cost.

In the same section J. C. Hobbs, Mem.Am.Soc.M.E., describes a gas-fired boiler installation (from a paper before the Engineers' Society of Western Pennsylvania). This installation is of interest in many respects as several constructional difficulties had to be overcome. Among other things, it describes a horizontal-type baffle in the boilers, and a special gas burner permitting an absolute control of the relative quantities of gas and air.

Heat transfer from air to pipes forms the subject of an extensive discussion by Charles H. Herter before the American Society of Refrigerating Engineers. One of the conclusions arrived at by the writer is that, within certain limits of velocity of flow, the coefficient of heat transfer from air to pipe varies approximately as the two-thirds power of the velocity instead of as the square root of the velocity as has frequently been stated.

Friction of slime pulp in pipes is discussed by E. J. Laschinger in a paper before the South African Institution of Engineers and is abstracted in the section Varia.

REVIEW OF ENGINEERING PERIODICALS

For Articles on Subjects Relating to the War, see Aeronautics, Firing and Fuel, Munitions, Railroad Engineering, Varia.

Aeronautics

INTERNATIONAL AIRCRAFT STANDARDS. The following standards were recently adopted by the International Aircraft Standards Board:

Specification for Soft Solder. The specification determines the composition of the solder and, among other things, demands that it be made from new tin and commercially pure new lead.

Babbitt Metal for Bronze-Backed Bearings. The specification determines the composition of the material and the methods for taking a sample for analysis and of manufacture. No scrap is permitted to be used other than that produced in the manufacturers' own plants, and which is of the same composition as the material specified.

Seamless Brass Tubes. The specification determines the composition of the material, method of manufacture, physical properties and tests. It is stated that this tubing is resistant to the corrosive action of salt water, salt air and gases. As regards tests, the following are specified: flattening test, expanding test, and hydrostatic pressure test, in the latter case with a tensile stress of 7000 lb. per sq. in. in the tube, but in no case shall a test pressure of more than 1000 lb. per sq. in. be required. A table of tolerances of outside diameters and wall thicknesses is also given. Among other things, it is stated that when no length is specified, the tubes may be shipped in stack length of 10 ft. to 14 ft. When ordered in definite lengths, no length shall be less than that specified.

Phosphor-Bronze Castings for Bearings.

Cold-Rolled or Drawn Carbon-Steel Bars. A table is given showing the physical properties indicated by a tensile test; namely, minimum tensile strength, minimum yield point, minimum elongation in 2 in. or proportion gage length, and minimum reduction of area for bars under 0.75 in. diameter of width across the flats from 0.75 to 1.50 in. and over 1.50 in. The composition is indicated with maximum phosphorus 0.045 and maximum sulphur 0.050, except for electric- or crucible-furnace steel, where the maximum allowable percentage of phosphorus and sulphur may, at the option of the purchaser, be limited to 0.034 per cent.

ANVÄNDANDET AF LOGARITMISKA POLARKURVOR, VID BERÄKNING AF FLYGMASKINER, Henry Kjellson, *Teknisk Tidskrift*, Mekanik, 47 Arg., Häft 10, October 10, 1917, pp. 85-87, 3 figs. Application of logarithmic polar curves to calculations of heavier-than-air flying machines.

THE SOPWITH TRIPLANE. *Automotive Industries*, vol. 37, no. 24, December 13, 1917, p. 1044.

THE 160 HP. BENZ AND MERCEDES AIRCRAFT ENGINES COMPARED. *Aviation*, vol. 3, no. 9, December 1, 1917, pp. 610-615, 31 figs., 8 tables. Comparative data are given as to the general detailed dimensions, friction losses in engines, gas velocities, inertia forces, valve details, power curves, crankshaft dimensions, etc. Various parts of the two engines are illustrated side by side so as to show the respective constructions.

AIRSCREW ANALYSIS, A. F. Zahm. *Aviation*, vol. 3, no. 9, December 1, 1917, pp. 601-608, 15 figs. Aerodynamic analysis of the operation of an airscrew, followed by a stress analysis. Among other things, the writer shows a propeller computer which is a kind of slide rule by which the thrust efficiency and various intensive properties of a propeller blade can be quickly derived.

SOME NOTES OF THE AIRSCREW AND THE PROBLEM OF OPTIMUM DIAMETER, E. P. King. *Aeronautics*, vol. 13, no. 210 (new series), October 24, 1917, pp. 308-314, 6 figs. Discussion of a method of determining the best diameter for a propeller, such method to be employed in a particular case where restrictions as to engine power, speed and revolutions are completely defined. The writer attempts to reconcile the Newtonian method with the blade method and expresses the belief that there is no real discrepancy between the two methods, except in quantities utilized.

FRENCH AND BRITISH STATIONARY AERO ENGINES. *Flight*, no. 462 (no. 44, vol. 9), Nov. 1, 1917, pp. 1137-1139, 16 figs.

BIPLAN ALLEMAND BI-MOTEUR TRIPLACE FRIEDRICHSHAFEN, 450 HP., TYPE G H. *L'Aérophile*, 25 Annee, nos. 19-20, October 1-15, 1917. Description of a twin-engined three-passenger German biplane carrying 450 hp. in engines.

METAL IN AEROPLANE CONSTRUCTION, A. Pomilio. *Aerial Age Weekly*, vol. 6, no. 9, November 12, 1917, p. 378.

ECONOMY OF TIGHT AIR HOSE CONNECTIONS, Glenn B. Harris. *American Machinist*, vol. 47, no. 23, December 6, 1917, pp. 985-986. Points out the frequent occurrence of costly leaks in air lines and hose, and recommends a number of remedies to prevent the costly waste of power.

Air Engineering

MEASURING AIR DELIVERED BY A TURBO-BLOWER, Thomas G. Estep, Jr. In the measurement of air delivered by a turbo-blower to blast furnaces a new problem has been presented to engineers. It is very essential that the volume of air delivered to the furnace be known at all times, and it is even desirable that a continuous record of this quantity be obtained so that a comparative study of the furnace operation can be made.

The blower itself does not give any means of determining this quantity. On the other hand, as it produces a steady flow, any of the approved methods of measuring gases can be used, the only question being to select the most accurate and simple method. A pitot tube in the intake pipe suggests itself as a simple means of measurement, but before such an installation will give reasonably accurate results certain factors must be taken into consideration, such as the uniformity of the internal diameter of the intake pipe, the possibility of eddy currents in the pipe due to the presence of ring seams, and finally the possibility of the intake pipe being so short that the flow does not become uniform before being measured.

The writer recommends as the best solution a combination of a standard orifice and a pitot tube. The standard orifice may be placed in the end of the intake pipe directly under the

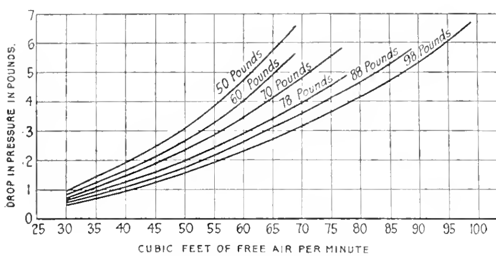

FIG. 1 DROP IN PRESSURE IN WOVEN HOSE AGAINST AIR DELIVERED AT DIFFERENT PRESSURES

hood, and the pitot tube used to measure the velocity of the air leaving the orifice.

With this arrangement practically no changes are required in the intake pipe. The hood may have to be raised a little in order to install a screen and give a free inlet to the orifice. Some tests made at the laboratories of the Carnegie Institute of Technology showed that if the hood was at least one-quarter the diameter of the pipe away from the orifice it would have no influence on the flow.

With the orifice at the end of the pipe the velocity of approach is zero, which facilitates the construction of the chart of the recording mechanism. Further, with this location of the orifice, static-pressure determinations are not necessary, and the pitot tube in reality becomes a simple impact tube, with just one connection to the recording device.

The length of the intake pipe has no influence on the measurements. If the orifice diameter bears the proper relation to the pipe diameter, the loss in pressure in negligible. Carnot many years ago proposed an equation for this loss, as follows:

$$\text{Lost head} = \frac{(V - V_1)^2}{2g}$$

where V_1 = velocity of fluid in pipe, ft. per sec.
V_2 = velocity of fluid in orifice, ft. per sec.
g = acceleration due to gravity, ft. per sec.

and the lost head is in feet of the fluid being measured. Tests made at the Carnegie Institute of Technology showed that this equation will give fairly close results. When the velocities are low the calculated loss is too high, and when the velocities are high the equation gives results too low. Over the range of velocities used in the tests, the variation of the actual and calculated loss did not exceed 7 per cent. If an orifice diameter of about six-tenths of the pipe diameter is used, and the lost head reduced to actual additional horsepower required to drive the turbo-blower, it is found that it amounts to less than one half of one per cent. (*The Blast Furnace and Steel Plant*, vol. 5, no. 12, December 1917, pp. 558-559, 1 fig., *pe*)

DROP OF PRESSURE IN COMPRESSED-AIR HOSE, Walter S. Weeks. Data of tests made last year under the writer's direction in the Mining College of the University of California to determine the drop in pressure that compressed air undergoes in passing through a 50-ft. length of commercial air-drill hose.

The tests were made on ¾- and 1-in. hose, and the results are presented in the form of charts, of which the one for the ¾-in. hose is reproduced in Fig. 1. Approximate tests were also made on the drop through the fittings alone, but this proved to be quite negligible.

The writer also makes some practical suggestions. It is necessary to have the hole in the hose of the specified size. The hose with the most "give" has the least drop in pressure, because when it is under pressure the diameter of the hose is slightly increased. Wire-wound hose is very rigid, and in addition often corrugated by the tight winding. These corrugations increase friction and constrict the opening. (*Western Engineering*, vol. 8, no. 11, November 1917, pp. 434-435, 3 figs., *e*)

Attention is called in this connection to the article, Economy of Tight Air-Hose Connections, Glenn B. Harris, *American Machinist*, vol. 47, no. 23, December 6, 1917, pp. 985-986.

Cooling

MECHANICAL WATER COOLING ON THE "HEENAN" PRINCIPLE. *Indian and Eastern Engineer*, New Series, vol. 41, no. 13, September 1917, pp. 85-86, 2 figs. Description of the "Heenan" cooler applied particularly for cooling jacket water of stationary gas engines. The cooler consists of cylinders built up of galvanized sheeting wound into the form of a spiral with the air space to each convolution. It will be described more fully in an early issue of THE JOURNAL.

Engineering Materials

HARDENING OF ALUMINUM BRONZE. According to an article in the *Giesserei Zeitung* for June 1, aluminum bronzes can be improved by thermal treatment. When they contain less than 7 per cent copper, the thermal treatment will not affect the properties much. Higher-grade bronzes can be hardened, however, and by the further addition of iron, silicon and other elements the mechanical properties of the alloys can be much varied. Thus, e.g., bronzes can be prepared having a Brinell hardness of 100 without being brittle. An aluminum bronze resembling in its mechanical properties a 0.35 carbon Swedish steel was given hardness values ranging from 100 to 260 by various thermal treatments; such bronzes of great hardness will answer as bearing metals even for high speeds. The following figures are given as to the properties of a 10 per cent aluminum bronze containing some titanium, the percentage of which is not quoted:

	Bronze as Cast.	Quenched Bronze.	After Thermal Treatment at Different Temperatures
Limit of elasticity....	9.6	19.8	27.7 to 19.2 kg. per sq. cm.
Tensile strength......	51.8	73.6	67.7 to 64 kg. per sq. cm.
Elongation	19.5	1.0	5.5 to 1.4 per cent
Contraction of area...	33.7	0.8	9 to 18.5 per cent
Brinell hardness......	100	262	158 to 140

(*The Journal of Industrial and Engineering Chemistry*, vol. 9, no. 12. December 1917, pp. 1144, *p*)

TESTS OF CORK FOR FRICTION CLUTCHES AND OTHER SIMILAR PURPOSES, G. G. Becknell and C. N. Weurich. *American Machinist*, vol. 47, no. 23, December 6, 1917, p. 972. Data on cork tests obtained in the laboratory of the University of Pittsburgh, including a summary of coefficients of friction. Also data with charred cork to determine the value of cork in dry-clutch work where intense heat is likely to be developed.

HYDRATED LIME AND ITS QUALIFICATIONS AS A STRUCTURAL MATERIAL, Bela Nagy. *Proceedings of The Engineers' Society of Western Pennsylvania*, vol. 33, no. 7, October 1917, pp. 457-473, 7 figs.

RECHERCHES SUR LA DILATION THERMIQUE ET SUR LA VITESSE DE DISSOLUTION DES ACIERS AU CARBONE, Joh. Driesen. *Revue de Métallurgie*, 14e Année, no. 5, September-October 1917, pp. 683-706, 14 figs., 8 tables. Investigation of thermal expansion and velocity of solution of carbon steels.

RUSTPROOFING IRON AND STEEL, Joseph W. Wunsch. *Machinery*, vol. 24, no. 4, December 1917, pp. 309-311, 3 figs.

THE MICROSTRUCTURE OF COMMERCIALLY PURE IRON, W. J. Brooke and F. F. Hunting. *Engineering*, vol. 104, no. 2707, November 16, 1917, pp. 532-534, 14 figs.

SUR LES PROPRIÉTÉS RÉFRACTAIRES DE LA MAGNÉSIE, H. Le-Chatelier and B. Bogitch. *Comptes Rendus Hebdomadaires des Séances de l'Académie des Sciences*, tome 165, no. 16, October 15, 1917, pp. 488-491, 1 fig., 2 tables. Discusses the refractory properties of magnesia.

PROPERTIES OF VARIOUS WOODS, compiled by A. Pomilio. *Aerial Age Weekly*, vol. 6, no. 9, November 12, 1917, p. 379.

Evaporators

TEST OF SCHUTTE AND KOERTING EVAPORATOR, M. C. Stuart. *Journal of the American Society of Naval Engineers*, vol. 29, no. 4, November 1917, pp. 725-738, 4 figs., 1 plate. An abstract of this paper will appear in an early issue of THE JOURNAL.

Firing and Fuel

CHART WITH WHICH TO MAKE VARIOUS RECORDS FOR COAL. Walter N. Polakov, Mem.Am.Soc.M.E. With the present scarcity of coal, the old slipshod manner of handling coal records should not be tolerated. By using the chart Fig. 2, the following information can be gained at a glance: (1) Quantity of coal on hand (bin or yard); (2) daily coal deliveries; (3) when unloading started and finished; (4) daily balance on hand; (5) heat value, ash and volatile contents of each delivery; (6) daily coal consumption; (7) coal consumption per kilowatt-hour; (8) cumulative consumption of coal to date; (9) on what day any certain coal was used; (10) the demurrage, if any.

The construction of the chart requires two main scales, namely, time (days of the month) and quantity (pounds of coal). The coal-consumed curve is started from zero on the first of the month, as shown, and grows gradually as coal is used from the overhead bin or yard each day. The vertical distance by which the curve rises from day to day gives the daily consumption, and the ordinate at the end of the line indicates the total coal used.

The amount of coal delivered is shown to the left of the coal-consumed curve, the grade being lettered opposite the line representing the quantity. The vertical bars representing the deliveries are divided to represent what portion of the total is in the overhead bin, what is in the yard pile, and how much is ready for unloading from the barges or cars. As the contents of each barge or car are consumed, the length of the bar representing the amount of its contents is projected on the coal-consumed curve, indicating in this manner the duration of the period during which its load was utilized.

Whenever a new delivery is made, a new bar indicating the amount is started on the day when the barge or car arrived at

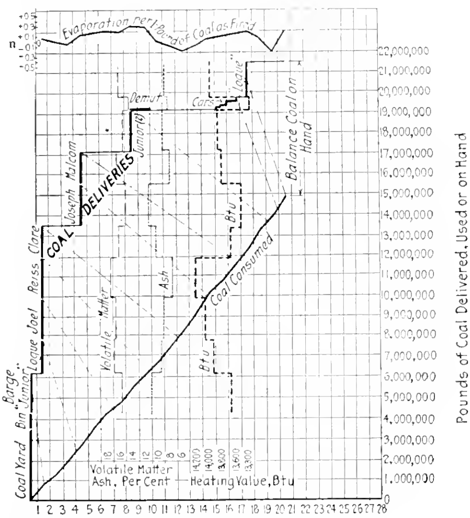

FIG. 2 METHOD OF RECORDING DATA REGARDING COAL SUPPLY, CONSUMPTION, ETC.

the dock or siding, while the horizontal line after each new delivery thus represents the time elapsed as periods between deliveries. The heavy part of the horizontal line represents the length of time during which the demurrage charges were accumulating.

The analysis of coal for each delivery may be shown as complete as desired, being indicated horizontally opposite each delivery. In the case illustrated, only the heating value, ash and volatile percentage are shown. In the upper part of the chart is a reference curve showing the evaporation per pound of coal. Any other relation, such as boiler efficiency or pounds of coal per kilowatt-hour, which may be of use can also be placed here.

To facilitate using these charts they can be plotted daily on cross-section tracing cloth, and blueprints can be sent from time to time (generally weekly) to the managers and purchasing agents. (*Electrical World*, vol. 70, no. 19, November 10, 1917, pp. 911-912, *p*)

Controlling Smoking Chimneys. Description of a method of electric signaling to indicate to the firemen the fact that the stack taking care of their set of boilers is smoking. The system described has been installed at the Duquesne Light Company's Brunots Island Power Station on an island in the Ohio River.

The station is served by 50 boilers having a total of 32,460 boiler hp., nominal rating. These boilers are served by 18 chimneys.

The system was designed mainly as an aid in preventing smoke. In each boiler room above the firing aisle is a red incandescent lamp enclosed in an opal globe so as to increase the glow of the lamp. Outside there is an observation house so situated that the observer has a view of all chimneys. In front of the observer is a switchboard through which he can control any of the red lamps.

The operation of the system is essentially as follows:

The operator observes that, say, No. 3 stack is making smoke corresponding to No. 2 chart. The switch of No. 3 circuit is thrown, which lights the lamp in front of the fireman who is operating the boilers served by No. 3 stack, and also brings the No. 3 recording pen of the time recorder into action. Both the combustion engineer and the water tender are available to asssist him, if needed. When the smoke has been reduced to correspond to No. 1 chart, the switch is opened, thus cutting out the lights and the pen of the time recorder.

The adoption of this system eliminated erroneous entries which might easily occur if the log system only were used. The charts are changed daily and filed for future reference. (*Power*, vol. 46, no. 22, November 27, 1917, pp. 718-720, 4 figs., *g*)

Hydraulics

Reversal of Water Wheel to Absorb Energy During Test. In the cross-cut hydroelectric plant built for the U. S. Reclamation Service on the Salt River Reclamation Project in Arizona, it was agreed that the high voltage and low amperage made it inadvisable to employ the usual water-rheostat method for absorbing the load in carrying out efficiency tests. It was therefore decided to connect the generator of the wheel under test with the generator of another unit in such way that the latter would be run as a motor. In this way the load would be taken up by the jets from the nozzles retarding the reverse rotation of the buckets.

This was done with hand regulation. One penstock was used for supplying water to the unit under test, and another for supplying water to the exciters and providing the load in the braking unit. With water admitted through the nozzles of the unit operated as a synchronous motor, electric energy was absorbed in direct relation to the hydraulic energy developed by water passing through its nozzles.

The stresses imposed on the buckets were directly opposite to those for which the unit was designed. Nevertheless, the motor unit was operated in this condition almost continuously for two days. While the Kingsbury bearing on the motor unit was designed for rotation in one direction only, it showed no undue distress throughout the entire run. (*Engineering News-Record*, vol. 79, no. 22, November 29, 1917, p. 1023, *t*)

Flow in Channels with Large Expansion Ratio, R. Kröner. (*Zeits. Vereines Deutsch. Ing.* 61, pp. 605-609, July 21, and pp. 630-633, July 28, 1917). This research comprises a detailed investigation of flow in close channels, following the work commenced by Andres and Hochschild. The complexity of the phenomena necessitates three-dimensional investigation of the flow. Special importance is attached to measurement and representation of losses; and the distribution of velocity and pressure is investigated. Air is used as the fluid medium in order to reduce the use of the large pipes required for close examination of stream lines, etc. The velocities of the flow are so low that the compressibility of air does not enter into the case. The Prandtl tube is used to measure the "velocity height" $\gamma w^2/2g$; where γ = specific gravity of air and w = velocity of flow. Double and treble search tubes are used in conjunction with manometers to determine the plane and direction of flow; the readings of the Prandtl tube and of a right-angled "book tube" (indicating the "energy" $e = p + \gamma w^2/2g$, where p = static pressure) are corrected according to the obliquity of stream flow. The experimental pipe used was 4 m. long and 250 mm. square. It was connected in the suction line of an electrically driven fan with suitable provision made to eliminate extraneous influence on the stream flow. The construction and arrangement of the measuring devices are illustrated in the original. A novel feature is a semi-automatic pen recorder which gives more accurate results than point-by-point readings, and also saves time and labor. A pivoted beam with two pressure bells of gasometer type insures, in conjunction with a relay system, that the driving motor runs at constant speed.

Insertion pieces of five different designs were used to reduce the canal section to a rectangular slot from 67.2 to 68.3 mm. wide in the several cases and with the full height of the channel. The constricting "nozzle" was of the same form in each case, and was 260 mm. long axially. In case A the constricting nozzle was used alone so that the channel increased abruptly in the ratio 1:3.62. In the other four cases fat sheets were used to provide rectangular expansion cones, the half expansion angles and the expansion ratios being: (I) 45 deg.; 1:3.7. (II) 22 deg. 34 min.; 1:3.64. (III) 12 deg.; 1:3.67. (IV) 5 deg. 53 min.; 1:3.69. The "nozzles" were symmetrical about a vertical plane through the axis of the channel, and were composed of zinc plates over wooden frames. Coördinates adopted were x positive in the direction of flow and reckoned from the narrowest section as zero; y and z from the right-hand upper corner of the main canal as viewed in the direction of flow, y positive to the left and z positive downward. Losses were reckoned from the narrowest section. Over 1000 curves were prepared during the main series of the tests. Considerable difficulty was experienced in some cases in restoring the exact conditions of flow which it

was desired to check or investigate; often a sudden change from one type of flow to another occurred without any particular reason being evident. Evaluation of test data and correction for certain errors are discussed in a portion of the original which cannot usefully be abstracted. Velocity, pressure, and loss of power are reduced to dimensionless quantities to permit of comparison between one channel and another, and lines of equal velocity are traced for those sections which show the velocity as a function of z to be very variable. The measurements show flow to be very asymmetric in cases A and I to III inclusive, also that different forms of flow are in the same channel. In case IV the flow jumps continually from one state to another. Pressure loss in case A showed a small departure from the square law; and the departure was comparatively large in case IV. Curves in the original show the more or less unstable alternative conditions of flow in some places. In no case has the power loss curve the cubic form which would correspond to a quadratic law of resistance; the curves are not harmonic among themselves, the losses being dependent on the extent of the back-flow zone.

The paper concludes with a comparison of the mechanical similarity between flow in air and water, based on channel IV. More definite conclusions and a discussion of the application of the results may be given in the detailed report of the research, which is to form a separate publication. Machine Shop

Attitude of Machine-Tool Builders to Motor Drive, C. E. Clewell. In order to gage the recent tendencies in machine-tool design which have been brought about at least partly by the growing use of motor drive, a number of typical questions were addressed to representative machine-tool builders. The article here abstracted represents a digest of the answers obtained. Besides the general expression of opinion, the various manufacturers indicated also the approximate percentage of output supplied for individual motor drive, group electric drive and straight-line shaft drive, and recent changes in machine tools adapting them specifically to motor drive.

From these data it appears that a very large percentage of machines of the majority of machine-tool manufacturers are supplied for electric drive.

The following represents in a general manner the expression of the attitude of the different companies toward motor drive:

1 *Lodge & Shipley.* In general, group drive is preferred to individual drive, except in cases where a few machines are run on overtime or at night, and for the reversing control of planers and where crane operation is facilitated by the elimination of overhead shafting.

2 *Ingersoll Milling Machine Company.* Individual motor drive is preferred.

3 *Jones & Lamson.* The tendency is strongly toward motor-driven machinery, motors being used practically always on heavy machinery, and, where conditions permit, also on lighter lathes, drill presses and the like.

4 *Cincinnati Bickford Tool Company.* Not much choice is expressed between a speed box and a variable-speed motor for standard tools. For special schemes of mounting, the motor drive is preferable.

5 *International Machine Tool Company.* Individual motor drive is preferred to any other method of drive.

6 *Bridgeford Machine Tool Works.* Individual motor drive is preferred for machine tools requiring 20 hp. or more, group drive for machines which require not more than 5 hp. or 6 hp. All machines that are made by this company and have gear heads are heavy-duty, requiring 10 hp. to 15 hp. In 95 per cent of the cases involving these machines motor drive is specified. Very few geared-head machines are belt-driven.

7 *Cincinnati Planer Company.* Wherever possible, electrically driven tools are favored.

8 *Bausch Machine Tool Company.* Favorable to motor-driven machinery.

9 *Foster Machine Company.* About 80 per cent of the machine tools in this company's plants are individually motor-driven.

10 *American Tool Works Company.* The preference of this company for motor-driven or belt-driven machine tools is influenced entirely by the conditions under which these tools are to be operated. Both types of machines are handled and each has a legitimate field of operation. (*Electrical World,* vol. 70, no. 29, November 24, 1917, pp. 994-997, 10 figs., *g*)

Munitions

The Inspection of Screw Gages for Munitions of War, H. J. Bingham-Powell. Attention in the inspection of gages has until recently been principally given only to correctness of the ruling diameters of the thread. The matter of pitch was largely disregarded, mainly because of the lack of an instrument which could measnre it from thread to thread in a rapid and exact manner independent of the personal equation of the operator.

Within the last two years, however, the question of pitch became prominent because of the accuracy required in the screw gages used on munition work.

A number of devices exist to measure the pitch based on the idea of measuring over a given number of threads. There are also a few machines to measure the pitch from thread to thread, but they have the defect that the accuracy of the operation depends on the care taken by the user. In England the pitch-measuring machine invented by Vidal is claimed to have overcome these troubles. Instead of the V-point is used a ball so arranged that it can bear evenly in the thread without the inclination of the spindle to which it is fixed. This ball is split with a lamina of mica interposed as insulation between the two portions. Electric circuits are made between the halves of the ball and the screw, and will only close when the ball is touching the slope of the thread on both sides. The spindle with the ball is connected to a longitudinal carrier of a triangular-truss form, with the spring arranged to press it toward the screw and so keep the ball in continually light contact with the thread. The adjustment given by the spring is so delicate that the carrier can be blown away from the contact by the breath. Since the ball and the screw must be quite clean and free from grease in order that the electric circuit may be established, the operator knows at all times that he has obtained a true contact on the thread without an intervening film of oil.

The writer was impressed by the fact that in all the existing designs the devices for insuring that the V-points or ball-pointed spindles resting in the screw bore equally on both sides of the thread depended on visual inspection, electric contact or reflection from a mirror on to a scale. The writer believes that a more convenient way to design the bearing on the thread is to arrange that this is fundamentally so without having to rely on electrical, optical or other devices to prove it. If a suitably sized ball is dropped into a screw, this ball must naturally assume an equal bearing on both slopes. If it were possible to have such a ball placed between guides so that its center was always over the axis of the screw and then to arrange a microscope moved by a micrometer head or similar measuring system and read down on it a point on the ball or else to an engraved line on the flat surface on a hemisphere instead of the complete ball, the solution would be complete.

However, there is no satisfactory way of knowing that the ball is in proper position. But if for the simple ball or half ball is substituted a ball-ended spindle that freely bears vertically or nearly vertically into the screw and is suitably guided along the axis from thread to thread, its movement being measured by a micrometer head, a satisfactory basis for designing the machine is found, and this is the principle adopted by the writer.

The paper describes and illustrates the machine in detail.

From this the writer proceeds to a discussion of measurement of the full effective core diameters of the Whitworth thread and of the full and effective diameters of the United States standard threads of plug screw gages and ring screw gages.

The writer recommends the following equipment for checking screw gages:

1 A pitch-measuring machine to read from thread to thread, to at least 1/10,000 of an inch
2 An appliance to take casts of ring screw gages, so arranged that the cast may be accurately set up in the pitch machine, or projection apparatus
3 A screw-measuring machine to check the governing diameters of a plug screw gage with accuracy to 1/10,000 of an inch. An equipment of " best " diameter and " maximum " diameter wires, and triangular pieces for the same
4 Thread micrometers, checked for accuracy, to use in conjunction with the screw-measuring machine
5 Ordinary micrometers, to measure full diameters, with Johansson blocks to keep them accurate
6 Complete sets of check plugs for the several diameters, pitch and form of thread of ring screw gages.

Finally, the equipment wonld be complete with a " projection " apparatus for observing the angle between the slopes of the thread and the form of the thread.

Possessing an inspection laboratory with these instruments, a gage maker is in a position to produce the very accurate screw gages employed in munitions work, and to meet all the requirements of the inspection departments of the several governments. (Pamphlet, N. Y., 1917)

SOME SPECIFICATIONS FOR MUNITIONS. The following list of specifications has been prepared by the Library of the Engineering Societies:

1896.—Specification for Steel for Gun-Barrels.—U. S. Government Specification, 1896. (Washington, D. C., Annual Report of the Chief of Ordnance, pp. 69-72.) Requirements are an elastic limit of 60,000 lb., tensile strength not under 100,000 lb., and an elongation of 15-20 per cent. The chemical limits were not to exceed: C, 0.50; Mn, 0.60; Si, 0.16; S, 0.034; P, 0.045. Analyses and tests are given of a large number of submitted samples, but none was quite up to the standard.

1897.—Armor-Piercing Projectiles (8-, 10- and 12-in. shot for the U. S. Government), 1897. (*The Engineer*, London, vol. 84, pp. 504-505.) Dimensioned sketches and specifications.

1907.—Qualities Necessary for Gun Steel, Carriage Steel, Spring Steel, Shield Steel (excluding armor-plate steel) and Shell Steel, 1907. (*Times Engrg. Suppl.*, May 22, p. 162). Specifications and tests of various steels in current use are given.

1913.—Bulleus, D. K., The Manufacture of Armor Plate, 1913. (*The Iron Age,* vol. 92, p. 953-954.) Details of the Harvey and Krupp processes. An American method described. Chemical composition and prices compared. Specifications for protective plates.

1915.—Specifications for High-Explosive Shells. Abstract of the Official British, French and Russian Government Specifications for high-explosive shells and fuses. New York, 1915. The Industrial Press, publishers of *Machinery,* 44 pp. (Pamphlet, p. 623.45 M. 185.) Gives details regarding Russian 3-in. H.-E. shell; Russian high-explosive percussion fuse; British H.-E. shells; British high-explosive shell fuse; French 75-mm. H.-E. shell.

1916.—French Specifications for Shell Steel. 1916. (*The Iron Age,* August 31, vol. 98, pp. 450-451.) Details regarding the specifications of the French government for shell steel. The bars are to be rolled or forged steel of the best quality, made either by the acid or basic open-hearth process, or electric-furnace processes, free from seams, floors, piping and porosity. The conditions of annealing are described, as well as those of temper drawing after quenching, and the mechanical requirements are also given. Twenty-eight per cent top discard and 4 per cent from the foot is stipulated, and the percentage chemical composition is specified as follows:

	Minimum	Maximum
C	0.30	...
Si	0.15	0.25
Mn	0.50	0.80
P	0.03	0.08
S	...	0.05

Railroad Engineering

REFRIGERATOR CARS FOR THE BALTIMORE & OHIO. The Baltimore & Ohio has recently constructed in its own shops some

refrigerator cars that contain interesting features of design.

Contrary to the customary practice, the insulation throughout the car is applied without any air space between the different layers. This was done because it has been found that it is difficult to maintain tight a car with the layers of insulation separated, due to the constant waving of the car. Further, by applying the various layers of insulation directly upon each other, the construction of the car is made less complicated and the insulation is better supported.

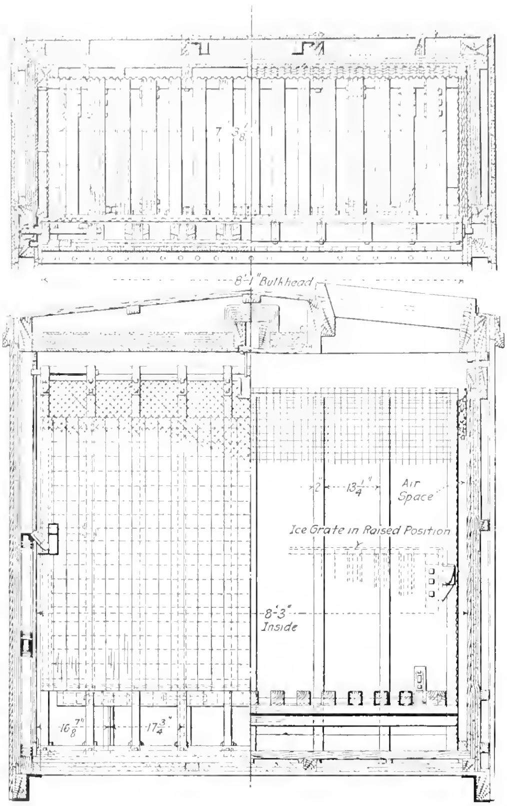

FIG. 3 SECTIONS THROUGH ICE BUNKERS SHOWING INSULATED BULKHEAD

It was the belief of the designers that better refrigeration is obtained if the air in the car has a direct and positive circulation. To secure this, the bulkhead of the ice chamber was made solid, with ample openings at the top and bottom, and the load held above the floor on racks. To obtain greater effectiveness from the ice, a wire netting is provided to hold it, which permits a free circulation of air around it. With the ice thus held away from the sides and end of the car less heat is absorbed through the car walls. The bulkhead is insulated (see Fig. 3) so that it will not transmit heat to the ice, but instead will guide the cold air down to the bottom of the car for circulation. The insulated bulkhead also prevents, to a large extent, the condensation of moisture on the car side of the bulkhead, which is liable to spoil the material placed against it.

The actual method of applying the insulation is shown in Fig. 4. The insulation passes around the corners of the car in continuous strips to better provide a tight insulated joint. At the top the outside layer of insulation is lapped up into the ceiling insulation around the side plate. The insulation of the ceiling is heavier than that on the sides, as it has been found that the absorption of heat is greater on the top of the car than on the sides. Since the weight of the ceiling with the insulation is too great for it to be firmly held by nails, $\frac{3}{4}$-in. to 3-in. support strips are placed at every third carline and are bolted at the carlines by $\frac{3}{8}$-in. bolts countersunk into the carlines.

Special care has been taken to properly insulate the walls surrounding the icebox, and the ice-hatch door is constructed with great care. The ice bunkers have a capacity of 15,000 lb. of ice. (*Railway Age Gazette*, vol. 63, no. 22, November 30, 1917, pp. 981-984, 6 figs., *d*)

STANDARDIZATION VERSUS IMPROVEMENT. "Standardization is a good thing within certain limits, but standards are not an end in themselves. They are only an aid to be applied with discretion." This is the statement made in an editorial article in the *Railway Review*. The writer proceeds somewhat as follows:

The standardization cult may easily become a mere drag on improvement, and in some cases the refuge of mental laziness and torpidity. The standards of today will be the deadwood of tomorrow, unless controlled by brains.

With particular reference to railroad engineering, in some things the advantages of standards are very perceptible. Freight cars travel all over the railroad system and need maintenance repairs wherever they happen to be. The advantage of standardizing parts that must work together, like couplers, and of dimensions and locations, so that interchange-

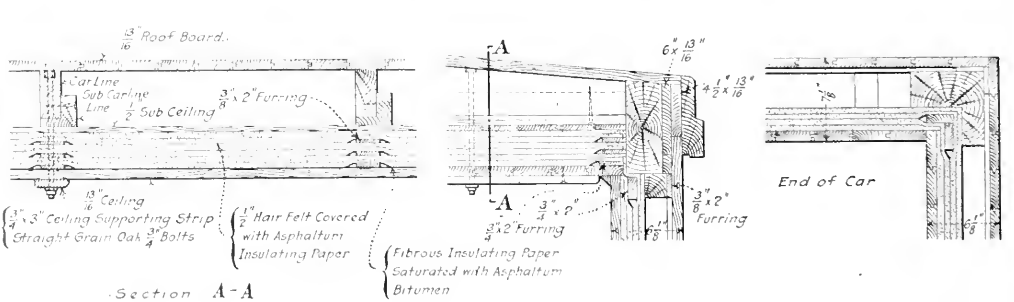

FIG. 4 METHOD OF APPLYING INSULATION TO BALTIMORE & OHIO REFRIGERATOR CARS

ability may be insured, are self-evident, but the freight car of today is not a perfect vehicle, and is in the process of evolution. This evolution can easily conform itself to such standards as will not hinder the way of improvement, but engineering improvement will not cease either by agreement or legislative mandate.

In the case of locomotives there is less real field for standardization as they stay on their own roads. They must operate with different fuels and different waters over varying grades and curves, and are subject to numerous conditions which stationary power plants do not have to contend with.

The best results are to be obtained by designing the machine for the service conditions it is to meet, so that excessive standardization, if applied to locomotives, would militate against ultimate efficiency. (*Railway Review*, vol. 61, no. 19, November 10, 1917, pp. 581-583, *g*)

Nozzle Characteristics, G. Flügel. (*Zeits. Vereines Deutsch. Ing.* 61, pp. 650-655, Aug. 4, 1917). Notwithstanding many theoretical and experimental investigations into the question of the expansion of elastic media flowing through nozzles, there still remains a series of technically important phenomena which require explanation. In the present paper the nozzle effect is examined for the case of a medium conforming to given conditions and with unrestricted exit. By nozzle characteristics the author means curves which exhibit the relationship between the reaction force of velocity coefficient at constant initial pressure before the nozzle, and either the final pressure after expansion of the adiabatic exit velocity.

The average velocity first receives attention, and here the existence of the mean active velocity and its relationship to the actual mean velocity and to the square of the mean velocity, is made clear. Nozzles suitably enlarged are next dealt with, the calculation of the respective velocity coefficient being given. It is shown that the curve of velocity coefficient becomes steeper within the critical zone for increasing exit velocity. The author shows how the most favorable form of nozzle may be evolved when the conditions of flow are known. For nozzles of normal cross-section but with too small enlargement, the velocity coefficients may be calculated with perfect accuracy, and with a good approximation for nozzles of oblique cross-section when certain simplifications are made. The striking result is obtained that after decrease of back pressure, the velocity coefficient still grows and reaches its maximum value for high pressures, the worse the nozzle. A limiting inferior pressure is shown for nozzles with oblique section, from which the expansion conforms to other laws as in the intermediate zone. Finally, with nozzles of too great enlargement experiments are quoted showing the improbability of the so-called direct gas impact and an indirect confirmation of this consideration is indicated. The author opines that a better solution may be sought from analogy with incompressible liquids flowing through an enlarged canal. Under this assumption a suitable approximation for the velocity coefficients is given which corresponds better with reality. (*Science Abstracts*, vol. 20, no. 238, section A, October 31, 1917, pp. 451-2)

Purifying Circulating Water for Surface Condensers, W. Seyffert. (*Ver. d. Elektrizitätswerke*, Mitt. no. 191, April 1917. *Elektrot. u. Maschinenbau*, 35. p. 376, Aug. 5, 1917). Mechanical and chemical impurities in circulating water form more or less rapidly a hard crust in the condenser tubes. The rate of heat transfer is then reduced; so also are the quantity and velocity of water flow. Thus vacuum is lowered and the efficiency of the main engine decreases. Removal of deposits either mechanically or by acid involves interruption of service. It is better and cheaper to eliminate mechanical impurities in settling ponds, and to undertake such chemical purification as may be necessary. The Martin (Berlin) patent clarifier is more convenient than a series of settling ponds. Water enters the funnel-shaped bottom of a vertical container. Any sludge, etc., settles in the funnel-shaped bottom and clear water is siphoned away from the top. Starting is facilitated by connection to a vacuum line; subsequently, with the inlet, outlet and sludge pipe open, the apparatus is entirely automatic. A clarifier with drum diameter of 5 m., capable of dealing with 70 cu. m. of water per hour, occupies 25 to 30 sq. m., including attendance space. Grease, oil, and gas rise to the top and are removed periodically through a special outlet. Tests at the Waldenburg central station showed 83.8 per cent "purification efficiency" for such a clarifier; chemical purification was also necessary in this case. From 11 to 14 kg. of circulating water was lost per kw.-hr. by evaporation in the cooling towers (air temperature — 4.5 deg. to + 11 deg. cent.; circulating-water inlet 24 deg. to 39 deg., outlet 20 deg. to 27 deg.). Due to this evaporation deposits are precipitated on the laths and grooves of the cooling tower. The efficiency of the latter is reduced and the laths are endangered.

A Reisert water purifier (50 cu. m. per hr.) operating on the lime process is installed at Waldenburg. The apparatus includes a cylindrical reaction tank, a distributor, two Der-

vaux conical saturators, and a gravel filter bed, 12 sq. m. in surface. The whole equipment is in the open and can be operated even when the atmospheric temperature is — 25 deg. cent. Water is circulated by an electrically driven pump. A spray equipment, operated by compressed air, is used to wash the filter. This purifying plant has been in use since 1911, and has reduced the cost of cleaning condensers from 28-42 M. ($7.00-$10.50) once a fortnight to 15-20 M. ($3.75-$5.00) once in six months. During 1915 the total cost for purifying the circulating water was 1.61 pf. per cu. m. of water, or 0.03 pf. (0.0072 cent) per kw.-hr. generated. (*Science Abstracts*, vol. 20, no. 238, section B, October 31, 1917, p. 357)

CLEANING CONDENSER TUBES IN THEIR PLACE WITH HYDROCHLORIC ACID, G. M. Robertson. Description of a method for the removal of scale in condensers where the scale is of a limy nature.

Tests were made with the condenser containing 4725 brass tubes $\frac{5}{8}$ in. inside diameter, $\frac{3}{4}$ in. outside diameter, 14 ft. long, fitted in brass tube plates with the usual tape packings and ferrules. The water box is cast iron and the cover is mild steel. The condenser was frequently scraped with different types of scrapers, but this removed only the softer stuff while the hard lime scale remained. If scrapers are made tight enough and sharp enough to remove some of the hard scale then the tubes are apt to be damaged.

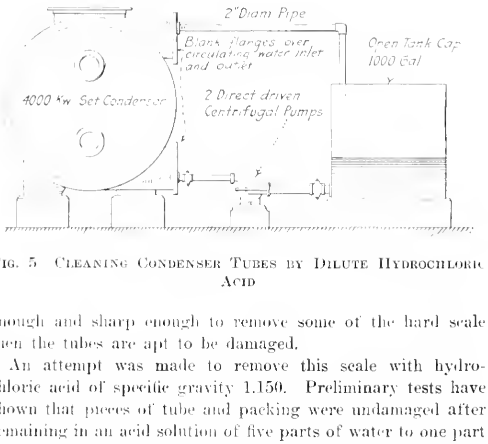

FIG. 5 CLEANING CONDENSER TUBES BY DILUTE HYDROCHLORIC ACID

An attempt was made to remove this scale with hydrochloric acid of specific gravity 1.150. Preliminary tests have shown that pieces of tube and packing were undamaged after remaining in an acid solution of five parts of water to one part of acid for 24 hours. It was also found that one ounce of acid dissolved half an ounce of scale, no matter what the strength of the solution was.

The test itself was carried out in the following way. First, a plain $\frac{1}{2}$-in. rod was pushed through every tube to make sure that they were clear. The water box and condenser covers were chipped clear of scale and the whole washed down with a hose. All the iron portions were given one coat of Bitmo solution to preserve them from the acid. The covers were put on.

The condenser was then filled with water from the 1000-gal. tank, Fig. 5, until the condenser was full and the tank had water just over the suction of the pump. The steam side of the condenser was also filled with water and a $\frac{3}{4}$-in. steam pipe fitted to the bottom of the condenser to warm the water, as acid is more active when warm. The steam was kept on the condenser for four hours, until the condenser was warm to the hand. Circulating was started from the tank through the condenser at 7.00 a.m., and one carboy of acid was added to the tank every twenty minutes until 10:30 a.m., one ton of acid being used. No more acid was added after 1:00 p.m. At 1:00 p.m. the pump was stopped, and the solution run into the tank through the pump until the top inspection door was clear. The top half of the condenser was then inspected through the inspection door, and some of the ferrules were showing clean. The inspection door was put on, and circulating started again, and more acid added to the tank at the same rate, and another ton supplied to tank by 5:00 p.m. The circulation was kept up until 7:00 p.m., when the solution was lowered again, and the top half again inspected. All the ferrules were showing clean, and there were only a few places between the ferrules where scale was still lodging. The inspection door was closed, and circulating restarted, and kept up until 11:00 p.m. The remaining solution was then thrown away to the vlei, from which our circulating water is taken, and water supplied to tank and circulated through the condenser to the vlei for five or six hours to wash away any acid that remained. The condenser covers were then taken off and the face of the tube plates, and as much through the tubes as possible, washed down with a hose with $\frac{5}{8}$-in. nozzle with about 30 lb. pressure. A few ferrules were leaking slightly at the threads; tightening up the ferrules stopped the leaks. There were no tubes leaking.

A measured sample of the solution flowing from the condenser to the tank was taken at 5:30 p.m. and analyzed for wastage of the brass tubes and ferrules. It was estimated that 5 lb. of copper from the tubes and ferrules had been dissolved. (The total weight of the copper was close to 34,000 lb.)

When the condenser was washed out after cleaning with acid, it was found that, as regards the iron parts, the Bitmo solution had been washed off in only a few small places, apparently where it had been painted over rust, but the iron work was not harmed. While the ferrules were clean when the condenser was washed out a considerable quantity of scale came out of the ends of the tubes, showing that the acid might have been kept circulating for some time longer. The scale which remained had been loosened, however, and was easily washed out.

In using the acid, it was poured from the carboy into an enameled jug holding about two gallons, and wet cloths were tied about the men's hands in case of spillage. Lime or lime water should be kept handy for the same emergency.

The 2-in. pipe shown from the top of the condenser might have been slightly larger to allow a clear escape to the gas. The circulating pump had a capacity of 2000 gal. per hour.

The cost of acid and preparing the condenser was £ 50 (about $250) and the whole work paid for itself in one week by the saving in coal due to improved vacuum.

Calcium and magnesium carbonates composed the larger portion of the scale. In addition, ferric oxide and silica were fairly abundant. (*The Journal of the South African Institution of Engineers*, vol. 15, no. 11, June 1917, pp. 276-279, 3 figs., *dp*)

A GAS-FIRED BOILER INSTALLATION, J. C. Hobbs, Mem.Am. Soc.M.E. Description of a boiler plant located in the basement of the William Penn Hotel, in Pittsburgh, which, in addition to generating power and heat for the hotel itself, also serves for heating an adjacent building.

Some of the features of construction are of considerable interest, as showing how some difficult problems of design have been effectively overcome.

The conditions affecting the construction and operation were rather severe. The plant is located under the hotel, the boiler-room floor being 50 ft. below the street surface. The plant must be operated noiselessly and produce no dirt.

The height of the stack has been fixed by the height of the hotel at about 350 ft. To take up the difference between the expansion of the steel stack and that of the building, the stack was made in short sections and supported from the steel frame of the building.

Because of the lack of area a rectangular stack was used, one joint to each two floors, and the joints instead of being left open were sealed by the special sand and asbestos joint shown in Fig. 6. Brick insulation was not used, because in the rectangular form the heat would have caused it to cave in. Instead asbestos insulation was used, as being thinner, smoother and giving more area.

As regards breeching, the principal points are the easy bends used, the method of caring for expansion and the application of the insulation.

Fig. 7 shows the details of the type of nozzle connection designed to permit expansion. The insulation is applied to the inside of the nozzle and to both the inside and outside of the breeching proper instead of on the outside only. It was deemed that the latter, while fairly effective as an insulation to reduce radiation, is dangerous, as it is possible even with a first-class boiler setting to have a temperature high enough to collapse a steel breeching if the heat is held in by the outside covering.

As regards boilers, the first ones installed were of the longitudinal type, B & W, rated at 600 hp., and were baffled with a special vertical baffle built of a high-temperature cement. The economic results obtained with this cement baffle were very good at first, but the cement soon began to fall out and the stack temperature to go up. Hence, a change was made to the horizontal-type baffle, shown in Fig. 6 (as applied to a cross-drum boiler having the same tube arrangement).

Careful consideration of local conditions has shown the advisability of using gas fuel, and a special gas burner, shown in Fig. 8, was developed. This burner permits an absolute control of the quantities of gas and air and likewise a thorough mixing of the two before their entering the furnace, without allowing the burner to fire back. Although the gas and air are kept separate up to within a few inches of the furnace, a mixture with a very fine subdivision is made, the gas and air being separated only by the walls of the small pipe.

No attempt has been made to make the gas and air control entirely automatic. It was felt that neither the air nor the gas should be controlled independently by an automatic device. It has been found that the amount of time required for gas and air adjustments is small, and it is believed that the advantage of the simplicity is more than enough to offset the costs of hand operation.

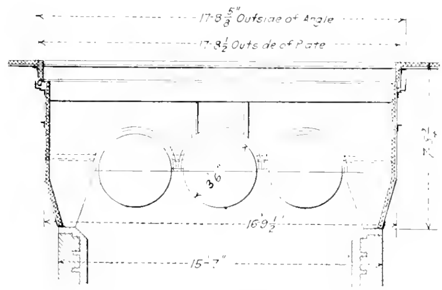

Fig. 6 Detail of Nozzle Connection in the Breeching

The proper adjustments to determine the correct ratio between the quantities of gas and air are determined by the use of a single U-tube. This, as will be noticed in Fig. 8, is connected direct to the gas chamber between the control valve and the mixing nozzles. A schedule of the correct position of the air damper has been determined by special and operating tests. For the sake of simplicity the damper position is indicated by the same figure which represents the gas pressure. The quantity of air is determined by the position of the air damper because the drop in pressure between the boiler room and the furnace is maintained constant at one-tenth of an inch of water. This figure was decided upon as a compromise between a high draft loss through the burner with its disad-

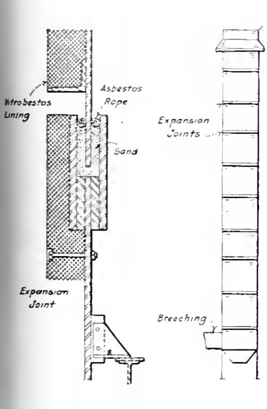

Fig 7

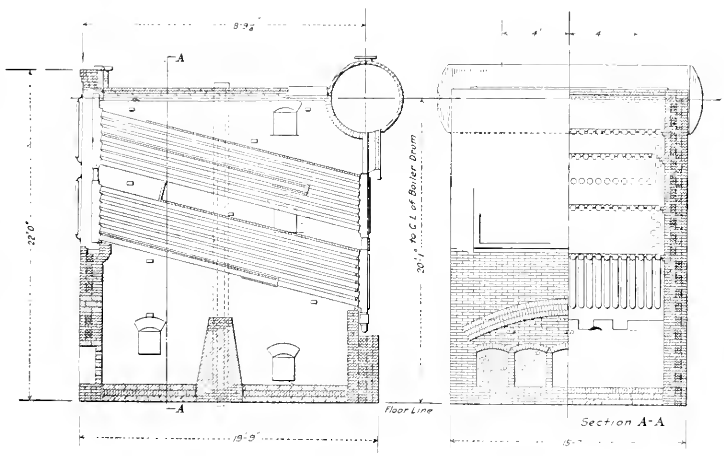

Fig. 8

Fig. 7 Arrangement and Detail of William Penn Hotel Stack
Fig. 8 System of Baffling and Wall Construction for Gas-Fired Boilers

vantage of causing an increased leakage loss through the setting, and a very low draft loss, a slight change of which would cause a large percentage of change in the quantity of air.

The brick work is simple, no checkerwork being used. With the horizontal baffling a medium-height bridge wall with the slightly raised pillar in front of each burner is all that is used, as shown in Fig. 9. The burner, as adopted, is in reality a multiple bunsen burner. Each burner consists of forty-eight 7/16-in. nozzles delivering gas from the manifold to the 2½-in. air openings.

As regards the economic performance of the plant, only the average monthly efficiencies are given in the paper. They vary from 77.2 per cent in November 1916 to 85.2 per cent in January 1917, the lower efficiencies being due to radiation loss at light loads. These figures do not represent a few hours or even a day, but are the average efficiencies for the entire month and show what has actually been accomplished by the regular operators.

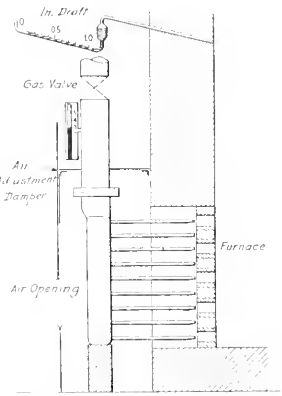

FIG. 9 ARRANGEMENT OF GAS BURNER

The writer ascribes the success of the installation to the following three factors:

1 The cutting out of the loss of draft through the damper and substituting the resistance of a longer path through the boilers, obtaining better heat absorption
2 The design of a durable burner which will give correct mixture under all conditions
3 The maintenance of the proper interest of the operators.

In the discussion which followed, L. C. Frohrieb, of the Federal Engineering Company, Pittsburgh, Pa., told about his tests of a 260-hp. water-tube boiler using natural gas for fuel in which an efficiency of 80 per cent was obtained. This was a three-pass horizontally baffled boiler with "C" tile on the lower row. One of the features was that there was no measurable draft loss through the entire setting, which was due to the fact that the setting was designed for coal.

A. G. Davis, of the Philadelphia Company, Pittsburgh, communicated a simple method of calculating the volume of flue gas which will be given over in the combustion of a unit volume of natural gas. The only data necessary for this calculation are an analysis of the natural gas to be used and a knowledge of the volume required. This method is based on an estimation of the oxygen required to burn the hydrocarbons present in the natural gas. (*Proceedings of the Engineers' Society of Western Pennsylvania*, vol. 33, no. 7, October 1917, pp. 421-456, 12 figs., *de*)

STEAM BOILERS AND ECONOMIZERS, M. R. Schulz (*Ver. d. Elektrizitätswerke*, Mitt. No. 189, March 1917. *Elektrot. u. Maschinenbau*, 35, p. 243, May 20, 1917). No boiler installation with natural draft can yield a higher thermal efficiency than 82 to 83 per cent; from 6 to 13 per cent of the value of the coal burnt goes to maintain the chimney draft, and therefore cannot be utilized in any other manner. With forced draft, up to 85 to 86 per cent of the thermal value of the coal may be utilized; if more than this be utilized, it is offset by power expenditure on the draft fan. Three tests on an inclined-tube boiler of 1000 sq. m. heating surface, with artificial draft and using coal of 7490 kg. cal. per kg. (13,480 B.t.u. per lb.), gave the following ranges of heat-balance percentages: Steam raising and superheating, 75.6-72.9; economizer, 11.1-11.3; total useful heat, 84.2-86.7; chimney loss, 10.1-11.3; incomplete combustion and radiation (boiler and economizer), 3.2-4.5 per cent; fan, 20-23 b.hp. The author finds that the principal error in steam trials is in determining flue-gas temperature, and is generally attributable to unsuitable pyrometer dimensions. As a check on economizer test results and claims, it may be taken that for 1 deg. temperature rise in feedwater in the best economizer, with no in-leakage of cold air, the temperature of the flue gases must be higher by 1.5 deg. cent. for 8 per cent CO_2 content; 2 deg. for 10 per cent, 2.5 deg. for 12 per cent, and 2.75 deg. for 13 per cent CO_2 content. In cast-iron economizers the difference is still greater. With a temperature gradient from 347 deg. to 233 deg. cent. (i. .e., 114 deg.) and 10.6 per cent CO_2, feedwater could not be raised 92 deg cent. in a cast-iron economizer; neither could water be warmed 89 deg. cent. in a wrought-iron economizer. Heat value at economizer outlet is 18.5 per cent with cast-iron, and 17.9 per cent with wrought-iron, apparatus. It does not follow that the lower the flue-gas temperature on leaving the boiler; the higher the efficiency of the utilization of coal. The CO_2 content as well as the gas temperature behind boiler or economizer must be considered. Tests on a water-tube boiler with Düsseldorf cast-iron economizer and forced draft showed 79 per cent thermal efficiency without economizer and 83.3 per cent efficiency with economizer. The author shows that flue-gas temperatures before and behind the economizer were measured inaccurately and losses were estimated too high. The gas temperatures were measured at unsuitable positions, too little attention was paid to CO_2 analysis, and it was overlooked that thermal value changed with decrease in CO_2 content, and that the CO_2 content was much lower at the chimney outlet than at the boiler outlet. The difference is 1 per cent and 3 per cent with cast-iron economizers of 144 and 250 sq. m., and increases considerably with artificial draft.

Boiler efficiency cannot be improved simply by forcing the draft. (*Science Abstracts*, Section B, Electrical Engineering, no. 238, October 31, 1917, pp. 354-355 *g*)

Thermodynamics

HEAT TRANSFER FROM AIR TO PIPES, Charles H. Herter. It appears that opinions regarding the rate of heat transfer from air to pipes differ considerably, and the writer cites a number of references showing a variation in k (coefficient of heat transfer from air to pipe in B.t.u. per hr., per sq. ft. of air contact surface, per deg. fahr. mean temperature difference between air and surface) from 13 to 1 B.t.u.

J. E. Seibel stated in 1916 that German engineers use the following values of k:

Air through metal to air .... 1.20 to 1.70 B.t.u.
Water through metal to air .... 2.15 to 3.15 B.t.u.

He also states that for ammonia vapor through iron coils to air, k is roundly estimated at 10 B.t.u., but does not explain why an ammonia-cooled pipe should cool air at a four-times greater rate than a brine-cooled pipe. In fact, the writer questions the existence of such a difference.

The writer also questions the correctness of Siebel's statement repeated in Marks' Mechanical Engineers' Handbook to the effect that 260 to 300 ft. of 1¼-in. pipe per ton refrigeration is a liberal allowance. He does not believe that this is liberal, because even with k as high as 2.5 B.t.u., the necessary temperature difference will be 42.4 deg. with 260 ft. and 36.7 deg. with 300 ft., and it is evident that the allowance made for pipe per ton should be doubled for economical operation.

R. W. Leonard, in a paper before the Canadian Society of Civil Engineers, October 1904, describes some tests on loss of heat from iron pipe with pipes exposed in vertical position to air outdoors in the shade and filled with hot water. From the data given, Mr. Herter calculated the value of k, and found it to be from 1.894 to 3.55 B.t.u. for pipes of various dimensions and various temperatures of air. The last value is for pipe exposed to wind blowing at 480 to 720 ft. per min.

In tests made by the Armstrong Cork Company, values were obtained varying for different conditions of test from 1.8 to 2.18 B.t.u. Various values of k are shown in Fig. 10.

Curve 1 represents values of k given in Kent's Mechanical Engineers' Pocket-Book, 1912, p. 677, for indirect hot-water radiators, where the mean temperature difference is seldom less than 100 deg. fahr. This curve probably applies to nested or deep radiators, the heat-transmitting capacity of which is only moderately high.

Curve 2 represents values obtained by passing known volumes of air through a boiler tube surrounded by steam. The formula applying to this curve is:

$$k = \frac{1}{0.026 + \frac{187}{v}}$$

where v = air velocity in ft. per min.

Curve 3 is based on data derived from Lorenz and Heinel. It gives the value of k for ordinary *brine pipes* to air, as in dry air coolers or coil bunkers with forced air circulation. This curve is intended for velocities exceeding 200 ft. per min., where, according to the authors, the influence of temperature difference disappears. The following formula for this curve is given in the original:

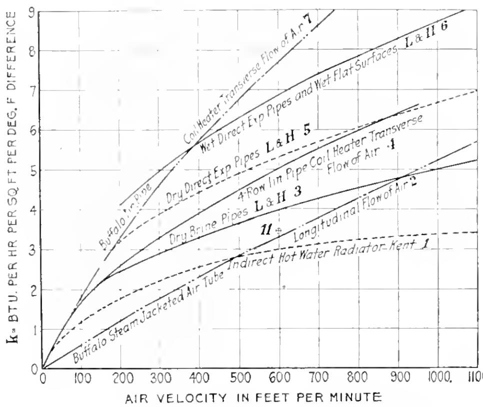

FIG. 10 HEAT TRANSFER CLAIMED BY VARIOUS INVESTIGATORS UNDER CONDITIONS INDICATED WITH AIR IN FORCED CIRCULATION

$$k = 2 + 10\sqrt{v}$$

in calories per hour per square meter per degree centigrade, where v = velocity in meters per second.

In English units, writing v in ft. per min., this formula would read:

$$k = 0.41 + 0.1458\sqrt{v} \text{ B.t.u.}$$

Curve 4 is taken from H. Recknagel, and from Rietschel, 1909. Up to 300 ft. per min. the values of k are those applying to single hot-water radiators. Above 300 ft. they apply to four-row 1-in. steam-coil heaters with the air passing through the heater perpendicular to the pipes.

Curve 5 represents values of k for *dry direct-expansion pipes,* expressed by Lorenz and Heinel by the following formula in metric units:

$$k = 16 \times \frac{2 + 10\sqrt{v}}{12} \text{ calories}$$

which, in English units, is equivalent to

$$1.333 \times (0.41 + 0.1458\sqrt{v}) \text{ B.t.u.}$$

Curve 6, giving values of k with *wetted direct-expansion pipes* as well as with wetted flat surfaces, is based on the following formula given by Lorenz and Heinel:

$$k = 2 + 18\sqrt{v}$$

in calories per hour per square meter per degree centigrade, of which one unit = 0.204817 B.t.u. per hr. per sq. ft. per deg. fahr.

Transformed into English units, this last equation becomes

$$k = 0.41 + 0.2626\sqrt{v}\ \text{B.t.u.}$$

Curve 7 represents the results of tests made on standard four-row indirect or *coil pipe heaters* composed of 1-in. pipes placed on 2⅝-in. centers, air flowing transversely through the heater. The figures of k obtained agree with the following formula:

$$k = \frac{1}{0.0447 + \dfrac{50.66}{v}}\ \text{B.t.u.}$$

where v = velocity of air through the clear area of the heater in feet per min. Up to 1200 ft. per min. they can be expressed by the approximate formula:

$$k = k_0\left(\frac{v}{v_0}\right)^{2/3}$$

which proves that up to 1200 ft. k varies approximately as the *two-thirds power of the velocity,* instead of as the *square root of the velocity,* as has frequently been stated by other investigators.

The writer also gives a simple equation representing the relation in B.t.u. per hr. per sq. ft. per deg. fahr. temperature difference in the case of flow of heat from one medium to another through metal walls of a pipe, and another equation covering the case of a pipe coated with paint or ice on its outer surface and a layer of congealed oil or grease on the inner surface.

He then proceeds to a discussion of tests by Nusselt previously reported in the Journal of the Society of German Engineers, 1909.

In the discussion which followed, F. L. Fairbanks, Mem. Am.Soc.M.E., called attention to the fact that it is quite impossible to secure an accurate heat-transfer test which will be constant, owing to the fact that all factors are variable, and the best thing is to secure some approximate figure which will cover the maximum and minimum conditions in refrigerating plants.

In refrigerating practice the tendency has been in some cases to use the minimum amount of surface that would do the work, and usually the lack of condenser surface has been dearly paid for in operation, because of the high pressure necessary to condense a given unit of gas. The writer has found it excellent economy to have surplus cooling and condensing surface to enable a plant to maintain reasonably high efficiency and economy in spite of the fluctuations which are bound to occur under the ordinary commercial operating conditions.

A. J. Wood and R. B. Fehr, Members Am.Soc.M.E., have discussed the factors involved in heat transmission from air to pipes and have classified these factors under the three fundamental heads of conduction, convection and radiation.

Tests have been carried out by the writers at Pennsylvania State College with the ultimate purpose of establishing constants for these factors. One of the phases of this investigation is the determination of temperature gradients. The importance of it lies in that the amount of heat emitted by a pipe, for example, is independent of the conditions prevailing inside the pipe, provided the surface temperature is the same for different cases, such as gas through metal to gas or liquid through metal to gas.

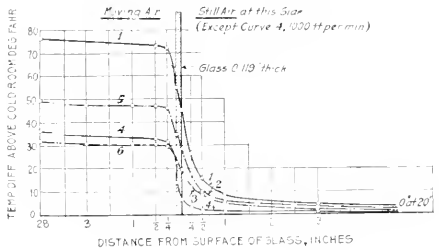

Fig. 11 Temperature Gradient on Each Side of Pane of Glass

Fig. 11 shows the results of a series of investigations on the distribution of the temperature drop from the inside of the test box through a pane of glass to the outside (cold) room. The air inside the box was agitated by an electric fan, while the air in the cold room was "still" (with normal convection) except for curve No. 4 as noted on the diagram. These test results, as obtained by electric-resistance thermometers, bring out the following: (*a*) That the "air films" offer by far the greater amount of resistance, as indicated by the large temperature drop on both sides; (*b*) that the glass, indicated by the small temperature drop, offers but a very small part of the total resistance to the flow of heat; (*c*) that the effect of moving air causes a marked change in the temperature drop on the two sides. (*A. S. R. E. Journal*, vol. 4, no. 3, November 1917, pp. 308-332, 6 figs.)

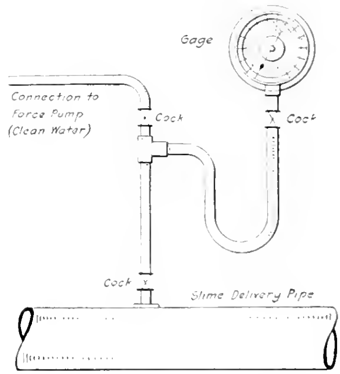

Fig. 12 Device for Measuring Slime Pressure by Bourdon Gage

Varia

Friction of Slime Pulp in Pipes, E. J. Laschinger. Data of some tests on the friction of slime pulp in steel pipes. The matter is of importance on the Rand, since in nearly all reduction plants there the slime is handled in pulp form by means of centrifugal pumps and piping.

The slime pulp consists of finely comminuted particles of rock (200 mesh and less) mixed with water in proportions

varying from 1 to 1 down to almost pure water. The solid particles, for the most part, consist of sandy or clayey constituents which are to a large extent colloidal, and fine, sharp particles of quartz which are crystalline. The fact that the interior of the pipes remains clean would indicate that the friction must be quite considerable, but not excessive, as proved by the very long life of the pipes.

At the beginning of the tests an initial difficulty had to be overcome. The pressures at various points in the pipe line were taken by means of the ordinary bourdon gages, mounted on the usual U-tubes screwed into the pipe. Owing to the sludgy nature of the thick slime pulp, it was found that the gages did not register the pressure correctly, which was due to a plug of solid matter forming somewhere in the U-tube, and interfering with the free transmission of pressure in the pipe to the gage. This was overcome by adopting the device shown in sketch, Fig. 12. The U-tube was filled with clean water at the start and before every gage reading clean water was forced through the gage connection by means of a hand pump, so as to make sure that the whole connection was clear of slime. In this way reliable and consistent readings were obtained.

The paper gives complete data obtained in the test. Only some of these, however, can be reported here.

It was found that the length of piping which would give a friction head equivalent to the velocity head in the case of the long middle section with only one bend is

$$L = \frac{D}{f}$$

where L = length in ft.

D = diameter in ft.

f = coefficient of friction = 0.0183 in this case.

In another place the figure 0.0177 is given for the overall coefficient of friction. On the whole, it has been found that the friction head for slime is about 13½ per cent less than for water. This latter figure has been confirmed in another series of tests with comparatively thicker pulp.

Since the friction head of ordinary slime pulp (measured in feet of slime) appears to be less than friction head of water (measured in feet of water), and since the pipe for the discharge of slime may have to be used for discharging water, a safe rule to the designer is to specify the pump speed, so as to elevate water to the required height, plus the friction in the pipe due to water, and the power of the motor driving the pump to elevate slime to about the same height. In practice this will mean a motor of about 50 per cent greater power than required for water pumping.

A further point to be borne in mind is to design the piping as straight as possible, avoiding sharp elbows, and particularly vertical drops of more than 20 ft.

In choosing a suitable size of piping, the velocity of flow should not be less than 4½ ft. per sec., and in most plants the velocity is from 6 to 7 ft. per sec. (*The Journal of the South African Institution of Engineers*, vol. 15, no. 11, June 1917, pp. 279-283, 1 fig., *e*)

Draft and Enrollment in Engineering Schools. In order to gage the effect of the draft on engineering schools, the *Engineering News-Record* sent a letter to 92 institutions requesting information as to the number of students enrolled at the beginning of the scholastic year for the period from 1912 to 1917 inclusive.

The data collected showed several interesting factors, among them the effect of the depression of 1914 upon enrollment and the remarkable increase in the number of students taking a chemical-engineering course. It was also found that in some schools the senior and junior classes were cut as much as 60 per cent by the operation of the selective draft and through voluntary enlistment. CLASSIFICATION OF ARTICLES

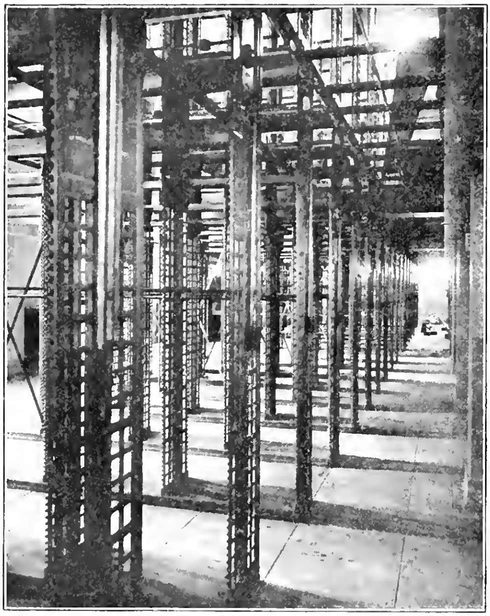
Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

LIBRARY NOTES AND BOOK REVIEWS

ARTICLES of interest from the Library of the four Founder Societies, selected list of accessions during the month, and reviews of books of special importance prepared by members of the A.S.M.E. and others particularly qualified.

THE illustration shows the new stack and work room, occupying the fourteenth floor of the United Engineering Society Building. This room, which has just been completed, will provide much needed accommodation for the book collection, which has outgrown the shelving originally provided and is now crowded to a point that interferes with prompt service.

The new stack will accommodate about 67,000 volumes, but as the Library has transferred one-half of the twelfth floor to the Founder Societies for storage room, the net gain in



PART VIEW OF NEW STACK FLOOR

shelving is only about fifty per cent of this amount. It will be possible, however, to erect additional book stacks in this room to a total capacity of approximately 100,000 volumes, which will care for the Library for some years.

The room is unusually well provided with daylight and an adequate system of electric light is being installed. No partitions have been built between the stacks and the space reserved for work rooms, thus permitting easy rearrangement at any time to meet changing requirements.

The stacks at present installed were formerly used in the Library of the American Society of Civil Engineers, and were very generously presented to us by the Society. The gift was an especially acceptable one, as it has saved not only the cost of a new stack, amounting to several thousand dollars, but also the long delay which would have been experienced in obtaining new construction at this time.

It is hoped that the new stack will be in use this month. It will enable the Library to arrange its books in better order, thus making the service to readers better. The vacated space on the twelfth floor will at the same time provide storage space for publications which is sadly needed by the Founder Societies.

War Libraries

The libraries established by the American Library Association at the Army training camps are filling a definite want by providing reading for the men and officers. The demands made on them, however, are so broad in scope that it is impossible to fill them all. Technical magazines are much appreciated, as well as those of literary interest.

The following communication from a corporal in training at Camp Wadsworth shows what is needed:

"I am a Civil Engineer and would like to be kept in touch with that profession. A periodical that I would like to read is the *Engineering News-Record*. As I am a railroad man I would also like to see the *Railroad Magazine*.

"I have also a friend in this Company with me who is a car tracer for a railroad corporation. He would like to get any books on the traffic end of railroading. If you wish, you can send anything in this line to the addresses below and we would be very grateful for your kindness."

Anyone wishing to meet this want can do so by sending the magazines to the Camp Librarian, Camp Wadsworth, Spartansburg, S. C. Similar gifts of technical journals would undoubtedly be appreciated by the men at other camps.

Notes

The Illuminating Engineering Society has presented to the Library some eighty volumes relating to the gas industry, among which are many of decided interest. These had been presented to them by Dr. William Paul Gerhard, but the society, believing that the conveniences of all would be best served by collecting all engineering material together, has secured Dr. Gerhard's consent to this disposition of his gift.

Mr. Edward Wegmann has presented to the Library a bound set of the contract specifications issued by the Aqueduct Commissioners of New York City from 1885 to 1901, covering the contracts in connection with the Croton Aqueduct. The estimates and bids for the construction of the various parts of the work have been inserted in this set, adding much to its value for reference.

BOOK REVIEWS

Empirical Formulas, by Theodore R. Running, Associate Professor of Mathematics, University of Michigan. John Wiley & Son, Inc., New York, 1917. Cloth, 6 x 9 in., 144 pp., 31 Figs. and 22 sets of reference curves, $1.40 net.

THIS is the nineteenth volume of the series of Mathematical Monographs edited by Mansfield Merriman and Robert S. Woodward. Although several books on mathematics devote one or more chapters to the derivation of empirical formulæ and there are a few very good magazine articles on the subject, this is the most complete treatise on the subject ever published and the first book worthy of the title.

The derivation of an empirical formula is the result of qualitative and quantitative mathematical analyses of certain data and the general methods are somewhat similar to those employed in qualitative and quantitative chemical analyses. The quality or form of the equation for a given set of data is found by testing with certain reagents such as logarithmic paper, tabulation of differences, graphs of quotients and products, etc., and the quantity or constants in the equation are found by substituting the coördinates of selected points by measurements from graphs, or from tabulated differences. A chemist may exercise all five of his senses in testing for the presence of various constituents in a chemical compound, but the engineer or mathematician is confined largely to his one sense of sight in observing the results of his reagents in determining the form of an equation that is best suited for the data under consideration.

There is a different test or reagent for each form of equation and the guide in using these is a set of reference curves, which are at times misleading. After the form of equation has been determined there should be no particular difficulty in determining the constants.

The subject-matter of the first five chapters of this book consists of discussions and applications of twenty-two tests or reagents based largely on the system of tabulated differences, which may be used to an advantage in many cases. These equations may be looked upon by the engineer as twenty-two tools that may be used in deriving equations that will satisfactorily represent the results expressed by data. It does seem that this number should be sufficient for such work, even though considerable difference of opinion is liable to be exercised in choosing such a collection. Many of the equations given by the author would be selected by most anyone familiar with the subject. Several of the equations given by him lead to rather complicated formulæ and should be avoided unless there is some exceptional reason for their adoption. Most any exponential formula is likely to be inconvenient or cumbersome to use, but fortunately the solutions of such may be readily performed by means of slide rules and charts.

Chapter V is devoted to the application of Fourier series to a number of ordinate schemes, which are applicable to periodic laws based on angular measurements such as wave analysis and certain theoretical phenomena. In Chapter VI is found a very good explanation of the application of the method of least squares to the derivation of empirical formulæ, in which the essentials are clearly and briefly given. Chapter VII deals with interpolation and differentiation of tabulated functions. It is of particular value in computations of precision in which a high degree of accuracy is desired. Chapter VIII gives some very practical work on numerical integration that should be useful to engineers.

The Appendix gives a very useful set of curves corresponding to each of the before mentioned twenty-two equations and is one of the most important features of the book.

Although the methods proposed by Prof. A. S. Langsdorf and Mr. Winslow H. Herschel are not pointed out as such, the principles involved in their methods are included in the author's system of tabular differences. The system adhered to by the author includes the principles of the calculus, although he uses rather simple algebraic equations in preference to differential equations and his demonstrations are very easily followed. The calculus is used in only two chapters. The matter in the other six chapters and appendix is of a very practical nature and may be comprehended without knowledge of the calculus as such.

More space could have been devoted to the use of logarithmic paper, even though this subject has been very well covered in other books. Brief discussions on dimensional consistency, when to apply certain tests, simplicity vs. accuracy and distinction between accuracy and precision, would not be out of place in such a book.

This is a practical book and should be particularly valuable to engineers engaged in research, design, time study, estimating costs, testing and any other work involving the use of tabular values derived from experimental or other observed data.

A. Lewis Jenkins.

ACCESSIONS TO THE LIBRARY

Abbott Enamel Sign Company. *New York City.* Catalogue, n. d.

Die Achate. By R. Ed. Liesegang. *Dresden, 1915.* Purchase.

Acquiring Wings. A Text on the Basic Principles Governing the Design and Operation of Modern Air Craft. By William B. Stout. N. Y., Moffat, Yard & Co., *New York, 1917.* Cloth, 5 x 7 in., 57 pp. 11 illus., $0.75. Gift of the publishers.

Air Brake Association. Proceedings of 24th Annual Convention, 1917. Gift of Association.

Air Power, naval, military, commercial. By Claude Grahame-White and Harry Harper. *New York, 1917.* Purchase.

Air Screws, an introduction to the aerofoil theory of screw propulsion. By M. A. S. Riach. *London, 1916.* Purchase.

Applied Methods of Scientific Management. By Frederic A. Parkhurst. 2d ed. John Wiley & Sons, Inc. *New York, 1917.* Cloth, 6 x 9 in., 337 pp., 55 illus., $2. Gift of the publisher.

American Bureau of Shipping. Rules for the classification and construction of Steel Ships. *New York, 1917.* Gift of American Bureau of Shipping.

American Institute of Architects. The Annuary, 1917. *Washington, 1917.* Gift of American Institute of Architects.

American Road Builders' Association. Proceedings of the 14th Annual Convention. *New York, 1917.* Gift of Association.

The Aniline Color, Dyestuff and Chemical Conditions from August 1, 1914 to April 1, 1917. By I. F. Stone. *n. p. 1917.* Gift of Arthur Worischek.

Asphalt and Asphalt Pavements, Papers on. By Clifford Richardson. 1912-1917. Gift of author.

Association of American Steel Manufacturers. Standard Methods of Sampling for Check Analysis adopted by the Association. 1912.

—— Standard practice governing the allowable variations in size and weight of hot rolled bars. Adopted by the Association 1910.

—— Standard specifications for concrete reinforcement bars rolled from billets, as adopted March 22, 1910, revised 1912 and Apr. 21, 1914.

—— Standard specifications for open hearth steel blooms, billets and slabs for forging purposes, as adopted by the association, 1912.

—— Standard specifications for rail steel concrete reinforcement bars, as adopted by the Association Apr. 20, 1912, revised Apr. 21, 1914.

——Standard specifications for standard open hearth and bessemer steel rails, as adopted July 7, 1914.

——Standard specifications for structural and boiler steel as adopted Aug. 9, 1895, revised 1896, 1902, 1903, 1912, 1914 and Sept. 1, 1916. Gift of the Association of American Steel Manufacturers.

Biographie, Bibliographie Analytique des Ecrits—Henri Poincaré. By Ernest Lebon. Ed. 2. *Paris, 1912.* Purchase.

Bliss, E. W. Company. Brooklyn, N. Y. General Catalogue of Presses, Dies and Special Machinery. 1914 edition.

The Book of the Machine Gun. By Major F. V. Longstaff and A. Hilliard Atteridge. Hugh Rees, Ltd., *London, 1917.* Cloth, 6 x 9 in., 14 + 337 + 84 pp., 69 illus., 16 plates. $3.50. Gift of Dodd, Mead & Co.

BRITISH RAILWAYS AND THE WAR. By F. A. McKenzie. *London, 1917.* Gift of W M. Dixon.

BRITISH WORKSHOPS AND THE WAR. By Christopher Addison. *London, 1917* Gift of E. G. Spilsbury.

BUILDING STONES AND CLAY. A handbook for architects and engineers. By Charles H. Richardson. (Published by the author). The Syracuse University Book Store *Syracuse, 1917.* Cloth, 6 x 9 in., 437 pp., 313 illus. $5.50. Gift of the publisher.

BUSINESS DIGEST, vols. 1-2, Jan.-June 1917. New York, 1917. Purchase.

CATSKILL WATER SUPPLY. A general description and brief history. October, 1917. *New York, 1917.* Gift of Alfred D. Flinn.

DETERIORATION IN THE HEATING VALUE OF COAL DURING STORAGE. (U. S. Bureau of Mines. Bulletin 136). *Washington, 1917.* Purchase.

DETERMINATION OF MOISTURE IN COKE. (U. S. Bureau of Mines. Technical Paper 148). *Washington, 1917.* Purchase.

EFFECT OF LOW TEMPERATURE OXIDATION ON THE HYDROGEN IN COAL AND THE CHANGE IN WEIGHT OF COAL ON DRYING. (U. S. Bureau of Mines. Technical Paper 98). *Washington, 1917.* Purchase.

ELECTRIC FURNACES IN THE IRON AND STEEL INDUSTRY. Ed. 2. By W. Rodenhauser, J. Schoenawa and C. H. vom Baur. *New York, 1917.* Purchase.

AN ELEMENTARY OUTLINE OF MECHANICAL PROCESSES. Giving a Brief Account of the Materials Used in Engineering Construction and of the Essential Features in the Methods of Producing them, also Describing Shop Processes and Equipment for the Shaping of Metals into Forms for Engineering and General Uses. Arranged for the Instruction of Midshipmen at the U. S. Naval Academy and for Students in General. By G. W. Danforth. The United States Naval Institute, *Annapolis, 1917.* Cloth, 6 x 9 in., 423 pp., 270 illus. Gift of the publisher.

THE ELEMENTS OF COAL MINING. By Daniel Burns. Edward Arnold, *London, 1917.* Cloth, 5 x 7 in., 236 pp., 113 illus. $1.10. Gift of Longmans, Green & Co.

ENGINEERING SOCIETIES OF THE UNITED STATES AND CANADA. Engineering News-Record, *New York, 1917.* Purchase.

THE ENGINEERS MANUAL. By Ralph G. Hudson. Assisted by Joseph Lipka, Howard B. Luther and Dean Peabody. John Wiley & Sons, Inc. *New York, 1917.* Cloth, 5 x 8 in., 315 pp., 227 illus., $2. Gift of the publisher.

FEDERAL VALUATION OF THE RAILROADS IN THE UNITED STATES. Statement prepared by H. C. Phillips, general secretary, of the Developments in connection with Federal Valuation as of November 1, 1917. Gift of Clemens Herschel.

FIELD FORTIFICATION. A Study of the Western Front in Europe 1914-1916. Reprinted from the *Infantry Journal,* 1917. The United States Infantry Association, *Washington, 1917.* Cloth, 7 x 10 in., 106 pp., 39 illus., $1. Gift of the publisher.

DIE FISCHWEGE AN WEHREN UND WASSERWERKEN IN DER SCHWEIZ. Von A. Härry. Publikationen des Schweizerischen Wasserwirtschafts-Verbandes Nr. 5. Rascher & Co., *Zurich* und *Leipzig, 1917.* Paper, 9 x 12 in., 115 pp., 101 illus., 4 francs. Gift of Schweizerischen Wasserwirtschafts-Verbandes.

GLOSSARY OF AVIATION TERMS (TERMES D'AVIATION). Compiled by Victor W. Pagé and Paul Montariol. N. Y., The Norman W. Henley Publishing Co., *New York, 1917.* Boards, 5 x 8 in., 94 pp. 14 pl. $1. Gift of the publisher.

GRUNDWASSERABSENKUNG BEI FUNDIERUNGSARBEITEN. By Wilhelm Kyrieleis. *Berlin, 1913.* Purchase.

HAND GRENADES. A Handbook on Rifle and Hand Grenades. Compiled and Illustrated by Major Graham M. Ainslie. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 5 x 7 in., 59 pp., 23 illus., $1.25. Gift of the publisher.

HEATING AND VENTILATION OF RESIDENCES. By James R. Willett. *Chicago, 1893.* Purchase.

HENRY'S LAW OF ABSORPTION OF GASES. BIBLIOGRAPHY. Gift of Samuel S. Wyer.

HOW TO FLY (The Flyer's Manual). A Practical Course of Training in Aviation. By Captain D. Gordon E. Re Vley. Arranged by Glad Lewis. Paul Elder & Co., *San Francisco, 1917.* Cloth, 4 x 6 in., 100 pp., $1. Gift of the publisher.

INORGANIC CHEMISTRY. By Horace G. Byers. Charles Scribner's Sons, *New York,* (copyright *1917*). Cloth, 5 x 8 in., 65 pp., 138 illus., $2.25. Gift of the publisher.

INTEGRAL CALCULUS. By H. B. Phillips. N. Y., John Wiley & Sons, Inc., *New York, 1917.* Cloth, 5 x 7 in., 194 pp., 124 illus., $1.25. Gift of the publisher.

INTER-OCEANIC CANAL OF NICARAGUA. Its history, physical condition, plans and prospects. *New York, 1892.* Purchase.

KATALOG DER HISTORISCHEN ABTEILUNG DER ERSTEN INTERNATIONALEN. LUFTSCHIFFAHRTS-AUSSTELLUNG (ILA) ZU FRANKFURT A. M. 1909. By Louis Liebmann and Gustav Wahl. *Frankfurt a. M., 1912.* Purchase.

DIE KRISTALLINEN SCHIEFER. Ed. 2. By U. Grubenmann. *Berlin, 1910.* Purchase.

LABORATORY DETERMINATION OF THE EXPLOSIBILITY OF COAL DUST AND AIR MIXTURES. (U. S. Bureau of Mines. Technical Paper 141). *Washington, 1917.* Purchase.

A LABORATORY MANUAL OF GENERAL CHEMISTRY. By Horace G. Byers. Charles Scribner's Sons, *New York* (copyright *1917*). Cloth, 5 x 8 in., 129 pp., 49 illus., $1. Gift of the publisher.

THE LIGHTING ART. Its Practice and Possibilities. By M. Luckiesh. McGraw-Hill Book Co., Inc. *New York, 1917.* Cloth, 6 x 5 in., 229 pp., 43 illus., $2.50. Gift of the publisher.

MACHINERY'S ENCYCLOPEDIA. A Work of Reference Covering Practical Mathematics and Mechanics, Machine Design, Machine Construction and Operation, Electrical, Gas, Hydraulic, and Steam Power Machinery, Metallurgy, and Kindred Subjects in the Engineering Field. Compiled and Edited by Erik Oberg and Franklin D. Jones. The Industrial Press. *New York, 1917.* Half leather, seven volumes, 8 x 11 in., illus., $36. Gift of the publisher.

MANUFACTURING COST. The Business Man's Publishing Co., *Detroit, 1907.* Gift of Arthur Worischek.

NACHWEIS, BESTIMMUNG UND TRENNUNG DER CHEMISCHEN ELEMENTE. Vols. 1-2. By A. Rüdisüle. *Bern, 1913.* Purchase.

NAVIGATION. By Harold Jacoby. The Macmillan Co., *New York, 1917.* Cloth, 5 x 8 in., 330 pp., 22 illus., $2.25. Gift of the publisher.

NEW SYSTEM OF CHEAP TRANSPORT FOR SIDE OR TRIBUTARY RAILWAY LINES. By William B. Hyde. *San Francisco, 1871.* Purchase.

NOUVELLES TABLES TRIGONOMETRIQUES FONDAMENTALES. By H. Andoyer. Vols. 1-2. *Paris, 1915.* Purchase.

ORE MINING METHODS. Comprising Descriptions of Methods of Support in Extraction of Ore, Detailed Descriptions of Methods of Development of Mines, of Stoping and Mining, Including Stull and Square-Set Mining, Filling and Caving Methods, Open Cut Work and a Discussion of Costs of Mining. By Walter R. Crane. 2d ed. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 6 x 9 in., 277 pp., 84 illus., $3.50. Gift of the publisher.

PRACTICAL BANKING. By O. Howard Wolfe. Chic., LaSalle Extension University. *Chicago, 1917.* Leather, 6 x 8 in., 290 pp., 95 illus., $2. Gift of the publisher.

PRACTICAL ELECTRICITY. By Terrell Croft. McGraw-Hill Book Co., Inc., *New York, 1917.* Cloth, 6 x 8 in., 14 + 646 pp., 548 illus., $2.50. Gift of the publisher.

RECHERCHES SUR L'EPURATION BIOLOGIQUE ET CHIMIQUE DES EAUX D'EGOT. Vol. 3-9. By A. Calmette. *Paris, 1908.* Purchase.

SEPARATE SYSTEM OF SEWERAGE. By E. C. Clarke. *n. p. 1881.* Purchase.

THE TECHNICAL ANALYSIS OF BRASS, AND THE NON-FERROUS ALLOYS. By William B. Price and Richard K. Meade. 2d edition, revised and enlarged. John Wiley and Sons, Inc., *New York, 1917.* Cloth, 5 x 8 in., 376 pp., 25 illus., $3. Gift of the publisher.

TECHNIC OF SURVEYING INSTRUMENTS AND METHODS. Including General and Detailed Instructions for Field and Office Work of Extended Students' Surveys. By Walter Loring Webb and John Charles Lounsbury Fish. John Wiley & Sons, Inc., *New York, 1917.* Leather. 4 x 7 in., 16 + 319 pp., 59 illus., $2. Gift of the publisher.

DIE THEORIE DER BODENSENKUNGEN IN KOHLENGEBIETEN. By A. H. Goldreich. *Berlin, 1913.* Purchase.

THE THEORY OF THE STEAM TURBINE. Ed. 2. By Alex. Jude. *London, 1910.* Purchase.

THE RELATION OF ENGINEERING TO INDUSTRIAL MANAGEMENT

By D. S. KIMBALL, ITHACA, N. Y.

In the preceding issue of The Journal was given a complete though necessarily somewhat condensed account of the Thirty-eighth Annual Meeting of The American Society of Mechanical Engineers. So much space was needed, however, to recount what have been referred to as the "war features" of this convention, that last month no more than a passing review of the usual technical proceedings of the meeting could be given. This issue contains an extended account of these proceedings, with discussions, oral and written, of the engineering papers presented. The issue therefore really constitutes a supplement to the preceding number.

Prefacing this discussion is an address by Prof. D. S. Kimball, member of the Society's Committee on Meetings, which is particularly timely in view of the tendency of the Society to interest itself in matters of "social economy," a course which is justified in the mind of every member at this critical period in the history of democracy.

We have all become somewhat accustomed to seeing the engineer called upon to perform new and strange duties, but few of us were prepared, I believe, to see an engineer called upon to undertake the greatest piece of constructive economics ever attempted. I refer to the work of Mr. Hoover, for Mr. Hoover is by training and practical experience a mining engineer. Yet this somewhat startling event is in full keeping with the trend of modern industry. Every day sees the duties and responsibilities of the engineer widened and it is difficult to see where the end will be. The engineer from the first has had a difficult time trying to define just what his field of activity is. This is necessarily so in any civilized community where the life of the people rests upon mechanical contrivances. Engineering, and mechanical engineering in particular, is an integral part of everyday life and necessarily assumes fresh aspects as the complexity of modern life increases. It will be increasingly difficult to set its limits and boundaries.

These matters have long been a cause for work and worry on the part of teachers in technical schools. The original conception of these institutions was to train men to design, build and operate machines within a narrowly defined field. Fifty years ago the term "mechanical engineer" conveyed a fairly distinct definition of activity; today it is almost meaningless.

The closely prescribed curriculum of the early engineering schools of years ago succeeded well in sending out men who in time made a place for themselves in the engineering field. But the men who passed through these schools were far from satisfied with the training they thus received. Their complaint, however, has not concerned the technical studies imposed upon them alone, but has embodied a demand for broader training in harmony with changing industrial conditions. The variety and scope of these demands have been great and have changed with the changing industrial field, but the demand for instruction in the subjects that pertain to industrial management has been constant, insistent and has grown steadily. Today there is not a first-class technical school in this country that is not recognizing this demand. The technical schools of today are not places where engineers, as defined by this term originally, are educated, but they are schools that prepare men, and women also, for industrial life in an amazingly broad manner. An examination of the list of graduates of any good technical school will show that twenty-five per cent of them remain in engineering pursuits in a narrow sense, the remainder going into a very wide variety of industrial pursuits. A very large and increasing proportion are found on the management side of industry.

It may be argued, of course, that while engineering may be a part of management, management is not part of engineering. And it may be truthfully stated that the engineer has been drawn over into management more because of his peculiar method of attacking problems than because of his technical or commercial knowledge; and that for this reason engineering colleges may well neglect these broader subjects and confine themselves to the time-honored engineering studies. While this may all be true theoretically, the fact remains that the industrial field is demanding men from the engineering schools who are well grounded in engineering and, in addition, know something of management. Hence we find such subjects as economics, psychology, logic, public speaking, and similar studies included in engineering curricula, and they appear no more or no less strange there than does an engineer as a food administrator.

Now what is true of the engineering schools is equally true of The American Society of Mechanical Engineers. The engineering colleges have lagged behind the industrial field in these matters, and the engineering societies in turn have lagged behind the colleges. It is interesting and instructive to read what the founders had in mind when the Society was organized in 1880. Dr. Robert H. Thurston, the first President, in his inaugural address states these objects to be "the promotion of the arts and sciences connected with engineering and mechanical construction." And the chairman of the preliminary meeting, Mr. A. L. Holley, enumerates in some detail the several branches of engineering contemplated as follows: metallurgy, railway engineering, machine-shop work, rolling mills, structural work, national defenses, shipbuilding, agricultural machinery and textile machinery, and concerning the latter he states, "The public would deem it quite outside of mechanical engineering." It is on this analysis as a basis that the first list of those eligible to election was made up, namely, mechanical engineers, civil engineers, military engineers, mining and metallurgical engineers and architects. And after reviewing the field, which to us now seems so restricted, Mr. Holley remarks, "I confess that in thinking over the range of mechanical engineering with reference to our proposed society I was astonished at its magnitude. I had never realized it before."

Only once in the statements made by the founders concern-

Presented at the Luncheon, on Thursday, December 6, 1917, at the Annual Meeting of The American Society of Mechanical Engineers.

ing the objects of the Society do we see a vision of what the future held for the Society when Dr. Thurston said, "Its province will be no less in the field of social economy than in that which has reference only to the individual needs of its members." This germ of thought has always remained in the Society and found its most widely known expression in Frederick W. Taylor's classic paper on Shop Management. But though this remarkable paper was presented to the world through the Society, comparatively little has been done by the Society to further this important line of thought. There is not even at this time a sub-committee on this field of work.

Ten years ago Prof. F. R. Hutton in his presidential address made an exhaustive review of the aims and activities of the Society which is well worth reading. He found that about fifty per cent of the membership at that time was classifiable under the headings "manufacturer," "shop executive" and "local manager." Yet the TRANSACTIONS for that year do not contain a single paper on industrial administration, though Taylor's masterpiece had been published three years before. An examination of any page of the year book will show that this relation has not changed and that the Society is far from being, strictly speaking, an engineering society, but that it represents industry in a very comprehensive and broad manner. That this view is recognized is clearly shown by the names of a few papers in the TRANSACTIONS for 1916, as for instance, How Does Industrial Valuation Differ from Public Utilities Valuation, or Graphical Control on the Exception Principle for the Executive.

What is true of the relation of mechanical engineering to management is also true of many other fields. Is the problem of electric welding one for the mechanical engineer or does it belong to the field of electrical engineering? Where shall we place oxy-acetylene welding or the thermit process? Accident prevention is certainly within the range of the Society's activity, so far as the mechanical features are concerned, but how far shall we interest ourselves in employers' compensation acts and the legislation that lies back of this important movement? Shall we discuss it as a problem in mechanical engineering or shall we also include the humane features of the problem? At the present moment a strong movement is on foot to interest engineers in the important problem of Americanization, and engineering schools are being urged to pay special attention to this matter. The subject is timely and important and no single class of men can do so much to promote it as the engineers. The problem is closely connected with industrial management; shall it become, therefore, a problem for engineers and engineering societies?

These intricate relations come before the Society largely through the work of the Committee on Meetings in passing upon papers to be presented before the Society. As would be expected from the foregoing, the papers offered cover a very wide range. The majority are well within the range of the field of engineering as commonly understood, a number are in the field of industrial management or in other fields equally removed from engineering in a strict sense. From this latter class the Committee on Meetings selects those that, in its opinion, can properly be presented, though even with this class of paper the Committee is not always unanimously agreed. Lastly, there are a number of papers presented that in the opinion of the Committee are so far removed from engineering as to make their presentation questionable, though they are sometimes valuable papers. The tendency, therefore, is rather to discourage papers which treat of matters on the "fringe" of engineering. I sometimes wonder if Taylor's paper on Shop Management, had it been presented by some one less known and under some other title, would have been accepted. It is fairly certain, moreover, that if more encouragement were given to papers of this broader character the Meetings Committee would be in receipt of many more of them, and it is not too much to expect that it would, in time, receive papers that would be as great in their field as is Taylor's classic. It is entirely a matter of how far the Society wishes to recognize its non-technical membership. It is noteworthy that the best collection of papers on the problem of employment of which I am aware is not found in the literature of engineering or industrial management, but is in the Annals of the American Academy of Political Science. I wonder how many employers have seen them. Quite a number of these papers were written by engineers and industrial executives. It is also to be noted that within the last year at least two societies have been started to carry out work that, in my opinion, belongs to this Society.

I believe the time has come, therefore, when the Society should redefine its aims and objects, and I would like to see an inquiry made into the aims and objects of our Society with a view to finding out how well the literature of the Society is meeting the wants of our membership. Or, putting it another way, if we are satisfied with the literature I think we should try to obtain a membership that is in harmony with it, a condition which, in my opinion, does not exist at present. And I should like to see such an inquiry made in a statesmanlike manner without reference to persons or groups of persons, but with the sole object of finding out what is best for the Society and what will insure to it an enduring future.

There will never be a better or more opportune time to consider this subject. Every loyal American is now asking himself what are his duties and responsibilities. Every technical school is facing a reorientation of its purposes and aims. As a nation we are facing a period of self-analysis that may result in changing some of our fundamental policies. I am not so sure, for instance, that we shall continue to be a "refuge for the oppressed of the earth" unless we are quite sure that the aforesaid oppressed are really in pursuit of the liberty and happiness that we all hold so dear. Americanization may indeed be a part of the work of all organized bodies that are interested in the existence of the Republic. If we have not at this moment a clear vision of whither we are tending, now is the time of all times to take stock of ourselves and to redirect our course, whether this course is in conformity with time honored definitions or not. Change is not necessarily synonymous with progress, but there is no progress without change. No one can doubt that the scientist and the engineer are to be the most important industrial figures of the near future. If we are faithful to our duties we shall be of greater importance politically and socially, but to accomplish this we must broaden our vision and get about our business, which is the industrial organization of our country.

At the beginning of January the Ordnance Department of the U. S. Army opened up a headquarters in the rooms of the Society for the purpose of recruiting and commissioning officers qualifying for ordnance service. The recruiting officers were Major Fred J. Miller, Capt. Henry C. Phipps, and Lieut. M. Goedecke, who comprised the examining board. Utilizing the Society's "war classification list," the board secured names of members of the Society qualified for the particular duties the Ordnance Department needed and issued calls to them. The work was kept up for several days, during which time upward of 1000 men presented themselves for examination.

POWER TEST HEARING AT ANNUAL MEETING

An Account of the Proceedings of the First Public Discussion of the A.S.M.E. Rules for Conducting Performance Tests of Power Plant Apparatus, Issued in 1915

THE public meeting of the Power Test Committee was held on Friday, December 7, and was called to order by President Hollis at 10 o'clock. The immediate object of the hearing was to discuss the various testing codes as published by the Society, and the ultimate object was to aid the Power Test Committee in such revisions as might be needed to make the codes of the greatest service to the profession, and to bring them up to date.

The members of the Power Test Committee, originally numbering eight, but increased later to twelve, were invited to sit at a table in front of the audience, and the members of the Advisory Board, composed of Society members identified with manufacturers and users of power-plant apparatus, appointed by the Council and numbering fifteen, were asked to take seats in the front row. Nine members of the main committee and nine of the Advisory Board availed themselves of this invitation.

President Hollis then addressed the meeting on the object of the hearing. He said that codes such as those under discussion were growing and changing, and that in order to make them valuable to the country at large there must be constant amendments and additions, the need for which arose not through oversight on the part of the Committee, but rather through changes in the demands of business and the use of better and different instruments. Moreover, although there might be a great many methods of generating power, and therefore a number of codes needed, there should be some definite principle underlying them all. The codes, he said, belonged no longer to the Society, but to all users of power, and therefore should represent the best effort and experience obtainable.

President Hollis explained that a program had been arranged in accordance with which the discussions of the various codes would be taken up at scheduled hours in order that the hearing might be conducted systematically. This program was closely adhered to, with the exception of the latter part when it was found that less time was needed than had been planned.

Mr. George H. Barrus, Chairman of the Power Test Committee, then presented a statement of the history of the Committee and the objects for calling the present hearing. Those present had been provided with a printed copy of his statement, which included the personnel of the Committee and of the Advisory Board. He stated that special written invitations had been mailed to some sixty engineering societies, organizations and associations interested in the subjects to be discussed. Similar invitations were sent to about forty manufacturing concerns and trade organizations, fifteen railroads and twenty-five colleges. Special invitations were sent to prominent engineers not members of the Society, to the United States Bureau of Standards, and to the Navy Department Bureau of Steam Engineering. Over half of these invitations had been accepted.

President Hollis then threw open the meeting for the discussion of the first thirty-three paragraphs of the codes embodying the General Instructions. It was decided that the discussion proceed without the reading of the paragraphs, as everyone in the audience had a copy of the complete report. It was also decided to omit the reading of all written discussions, as these would be placed in the hands of the Committee.

The oral discussion was opened by Capt. T. W. Kinkaid, head of the Engineering Experiment Station at Annapolis. Captain Kinkaid read a statement prepared by the engineers of the Experiment Station dealing with the General Instructions. Comments were made on some twenty of the subjects.

The remainder of the discussion on the first 33 paragraphs referred to details of the present general instructions, including changes in wording, methods and use of instruments, measurements, calibrations and standards. Those taking part were Messrs. Moss, Moody, Delany, Reynolds, Kruesi, Allerton, Vennum, and Greene. Messrs. Hirshfeld and Sparrow thought there should be a complete revision of the whole subject, and the President suggested that this latter point of view might be put into concrete form by a committee representing those who believed in a complete revision. He pointed out that the Society was not bound to abide by what the Power Test Committee had published up to the present time if something better and more useful could be suggested. Prof. Arthur M. Greene, Jr., thought it would be best to defer any such action until the codes had all been discussed, and in this view the President finally concurred. No further reference was made to the subject during the hearing. A little later, however, Mr. Moss expressed a conviction that no such complete revision as that suggested by Mr. Hirshfeld was needed.

Discussion of Code for Testing Boilers

At the request of the President, Captain Kinkaid continued with the portion of his discussion which related to the Code for Testing Boilers which was next in order for consideration.

E. B. Ricketts submitted to the Committee a form which he had used successfully for a number of years for reporting boiler tests and the instructions which were a part of the general scheme. He also included a chart from which many of the calculations of the boiler test could be made with a minimum of labor.

C. H. Delany made suggestions regarding tests of oil-fired boilers, and presented them to the Committee in written form. He wished the Code to include a separate tabulation for oil-fired boilers.

Prof. Charles R. Richards filed with the Committee a copy of a bulletin entitled A Study of Boiler Losses,[1] which included in an appendix a suggested code for boiler losses, a subject he considered inadequately handled in the present code.

R. Sanford Riley thought the rules for starting and stopping tests too definite for certain types of stokers where conditions in the fire were considerably different from those in hand-fired furnaces, Louis E. Strothman submitted a suggestion for the determination of boiler leakage, E. G. Bailey offered suggestions regarding the effect of the rate of steaming at the time of starting and stopping, and Captain Kinkaid presented some notes entitled, Correction for Difference in Quality of a Fuel Bed at the Beginning and at the End of a Coal Test.

[1] Bulletin No. 78, Engineering Experiment Station, University of Illinois, Urbana, Ill.

Steam-Engine Code

Sanford A. Moss opened the discussion on the Steam-Engine Code by offering his criticisms and amendments to certain sections of the Appendix dealing with this code. He also suggested that the Steam-Turbine Code come first and that the Steam-Engine Code refer to it, as he thought more tests were made of turbines than of engines.

Prof. Charles R. Richards discussed parts of the code at length and William L. De Baufre and Prof. A. G. Christie submitted written discussions.

Louis E. Strothman also joined in the discussion.

Steam-Turbine Code

B. F. Tillson suggested the CO_2 method of tests in cases where no surface condenser was in use.

S. A. Moss objected to the use of anything but a mercury gage for determining vacuum. He gave his views regarding corrections for different vacuums.

Thomas E. Keating seemed to be of the opinion that the code had never been "adopted," inasmuch as engineers who tested turbines did not seem to use it. Apparently, he said, there was something wrong with it, and if so it should be revised. He offered no specific suggestions as to what sort of revision would be acceptable, but suggested that representatives of turbine builders and turbine users be called in to assist in laying out a new code.

Prof. Arthur M. Greene, Jr., thought that the code should include some method of correcting for changed conditions which could be used in the case of small turbines where the expense of running a series of tests to determine these corrections would be out of the question.

A. H. Kruesi and J. P. Sparrow spoke regarding methods of determining vaccum.

Pumping-Engine Code

Frank F. Nickel submitted to the Committee a revised code. He was followed by Robert W. Allerton, who explained the need of a revised code from the standpoint of the use of centrifugal machinery. He also presented a scheme for making hydraulic measurements. In addition, he pleaded for a table of "terms" which would define absolutely such engineering terms as admit of several interpretations. Professor Greene also felt that an interpretation should be put upon certain terms by the Society so that an engineer might have an authority for his use of them.

At the close of this discussion, the meeting was adjourned for lunch, and reassembled at two o'clock with President Hollis again in the chair.

Compressor and Blower Code

Hugh V. Conrad, Secretary of the Compressed Air Society, opened the discussion on the Compressor and Blower Code by presenting to the Committee a number of suggestions regarding measurement of air. He called attention to the method recommended in the present code for measuring air and suggested that the orifice method be substituted.

Sanford A. Moss thought that the code should provide for the testing of electrically driven units. He also started a discussion on the term "free air," which was participated in by S. B. Redfield and William L. De Baufre. Mr. De Baufre suggested the preparation of a separate code for blowers and fans, as he thought much confusion resulted in trying to apply the Compressor Code to them.

Steam-Plant Code

The Steam-Plant Code elicited discussion from George C. Vennum and Philip E. Reynolds criticizing the phraseology of the code and calling attention to some ambiguity of terms. They also felt that condensers and pumps were not properly treated, and therefore presented suggestions for amendments to the code covering condensers of various kinds, air-removal apparatus and cooling towers.

Locomotive Code

The only speaker on the Locomotive Code was Prof. Charles R. Richards, who emphasized the need for incorporating some recognition of cinder losses. He also suggested that the Committee adopt the code used by the American Railway Master Mechanics' Association, and locomotive-testing experts be consulted.

Water-Wheel Code

Chairman Barrus opened the discussion on the Water-Wheel Code, the inadequacy of which seemed to be generally admitted by all speakers and interest in which seemed greatest of all. There were assembled in the audience as representative a group of hydraulic engineers, probably, as could be gathered together.

Chairman Barrus announced that the Committee had had under consideration for several months the work which was being done by the Turbine Builders' Association and the Machinery Builders' Society relative to standardizing the methods of conducting acceptance tests on hydraulic turbines, and that it had just received the official copy of the code which was the result of their work. This code, he said, would have the due consideration of the Committee and in many ways would be of assistance in their deliberations.

He also announced that at the invitation of the Council, the American Society of Civil Engineers, the American Institute of Electrical Engineers, and the National Electric Light Association had each appointed three representatives to confer with the Power Test Committee and to coöperate with them in the revision of the Water-Wheel Code. The conference was scheduled for the following week.

There seemed to be some delay in starting a discussion in which so many were not only interested but able to take intelligent part for the information of the Committee, until Lewis F. Moody called upon John L. Harper.

Mr. Harper said that until the present hearing his attention had never been called to the Water-Wheel Code. He pleaded for consistency of action in the various engineering societies interested in such a code if one was to be adopted, and seemed to feel that the basic need of any code was an accurate means of measuring water, suggesting, in spite of the difficulties which it apparently presented, the volumetric method. He was insistent in the statement that an adequate code, based upon correct principles, was an immediate necessity.

William M. White, who was interested in the code proposed by the Machinery Builders' Society, asserted that builders of water turbines had waited for years for some one to bring out a code under which they could make guarantees which they could carry out. He pointed out that the builders were interested in the measurement of water, but they did not care so much how it was measured as long as the turbine

was tested under the same conditions and with the use of the same weir coefficients as were assumed when the guarantee was made.

The remainder of the discussion, in which Messrs. Carle, Johnson, Moody, Allen, Herschel and Taylor took part, merely brought out the fact that all agreed as to the need of a revised code. To bring the matter to a head, Mr. White offered a resolution to the effect that it was the sense of the meeting that the code adopted by the Machinery Builders' Society was satisfactory and recommended it to the Committee for acceptance, but it was finally shown that the resolution was unnecessary.

Sub-Committees on Codes Proposed

Dr. Jacobus then spoke in the capacity of delegate from the Society of Naval Architects and Marine Engineers, suggesting the appointment of several sub-committees, each one of which was to have particular charge of a single test code, such as had already been done with reference to the Water-Wheel Code. The matter was put into the form of a resolution by Professor Allen to the effect that it was the sense of the meeting that such committees be appointed. The President assured the meeting that the Council would consider the resolution that very afternoon, and explained that it was the custom of the Council to consult with members of other societies on matters relating to their interests.

After considerable discussion, which centered around the relations of the subcommittees proposed, the Advisory Board and the Power Test Committee, the resolution was adopted.

During the discussion, N. A. Carle spoke of the American Engineering Standards Committee, of which he was a member. He said that the scheme of the committee was not the revision of standards but entirely that of acting as the connecting link between the societies and organizations who had established the standards. A standard, adopted by a society, would be referred to the committee for approval. If found acceptable to them, they would refer it to other societies interested in the subject considered, and upon universal approval, approve it as standard and recommend it for practice for one year. At the end of that time it would be stamped "American Engineering Standards." The result, he explained, would mean that some day it would be possible to say, "I want a power system of one million kilowatts capacity, American Engineering Standards."

President Hollis turned the chair over to Dr. Jacobus, who called upon Ervin G. Bailey to explain his system of measuring steam by means of carbon dioxide. The method, which is analogous to the salt-solution method used by hydraulic engineers for measuring water, was described in a paper presented to the Boston Section of the Society in May 1916.

The meeting closed with a discussion started by R. Sanford Riley on the errors in starting and stopping boiler tests. James W. Parker cited an extreme case of a test in which thirty tons of coal constituted the kindling fire, showing thereby the possibility of an enormous error which, he believed, could be avoided only by lengthening the duration of the test until the amounts of coal stored on the grates would bear an insignificant proportion to the total coal fired. Others agreed that this was a very uncertain element of any test, and expressed their belief that longer tests would avoid this error.

Chairman Jacobus asked for opinions on the question of sampling, and was answered by several members to the effect that the size of the sample should be as great as possible to insure the best results.

The object of the hearing having been accomplished and all of the codes disposed of, Chairman Jacobus adjourned the meeting at about 4:30 p.m.

IMPORTANT DISCUSSION ON VARIED POWER PLANT SUBJECTS

Proceedings of Session Devoted to Papers on Small Turbines, Waste of Coal, Bagasse as Fuel, Cooling of Water, and the Steam Motor

ONE of the busiest sessions of the Annual Meeting was the Power-Plant Session held on Wednesday afternoon, December 5, on the fifth floor of the Engineering Societies Building. Five papers, each one of them of sufficient importance to occupy the entire afternoon, were presented and discussed. Thanks to the enjoinder of the chairman, Mr. William B. Jackson, that all speakers carry the matters they wished to discuss well in their minds and come straight to the point, close attention was given to the work of the session and the long program was carried through very satisfactorily and without need of adjournment.

The five papers were on varied and timely topics in the power-plant field. They were all published in advance in The Journal and excited a wide interest, as evidenced by the large number of written discussions sent in prior to the meeting. The titles of the papers were: A Commercial Analysis of the Small-Turbine Situation, by W. J. A. London; Preventable Waste of Coal in the United States, by David Moffat Myers, member of the Committee of Consulting Engineers on Coal Conservation and Publicity coöperating with the Fuel Administrator; Bagasse as a Source of Fuel, by E. C. Freeland; The Cooling of Water for Power-Plant Purposes, by C. C. Thomas, and The Steam Motor in the Automotive Field, by E. T. Adams.

A running account of the discussion at the session, including pertinent abstracts from the written discussions, is given below. The full discussions, both oral and written, and the authors' final closures will be published in the Transactions, together with the revised papers, as usual.

A Commercial Analysis of the Small-Turbine Situation, by W. J. A. London

In his paper, which he presented in person, Mr. London developed a commercial analysis of the four types of small steam turbines now on the market and used for the driving of auxiliary machinery, dealing principally with non-condensing units. He said that in these high thermal efficiency is in many cases unnecessary on account of economic utilization of the exhaust steam, and as economy bears a definite relation to first cost, a highly efficient machine is often a mistaken investment. Moreover, operating conditions are generally such that the designer must sacrifice considerations of efficiency if they interfere in any measure with simplicity and durability.

The theoretical design, he thought, presented no difficulties, but the mechanical design is what determines success or absolute failure; and some of the problems involved and the

methods that have been employed in solving them successfully were indicated in the paper. Among these problems was that of alignment of the turbine with the driven unit, and in this connection he illustrated a two-bearing combined unit which has eliminated misalignment troubles.

He said that the average specification calls for very rigid guarantees as to steam consumption, speed regulation and load requirements that, in his opinion, are in most cases unnecessarily severe and merely tend to increase the cost of installation. After an extended survey of the situation, he was led to formulate a Code of Practice, given in an appendix to the paper. The adoption of this code would, he believed, bring about a reduction in selling prices, eliminate many of the unpleasant experiences which now often arise between manufacturers and customers, and thereby increase the popularity of the turbine-driven unit.

O. D. H. Bentley, in a written discussion, entered a defense of the type of turbine styled by the author as class "(*b*) Terry, Sturtevant and Bliss." He said that, other things being equal, the amount of energy a rotor will extract from the steam varies directly as the angular reversal. The author showed diagrammatically that the reversals in the rotor and redirecting chambers of the Terry, Sturtevant and Bliss turbines, all of which utilize the Riedler-Stumpf principle, were approximately 90 deg., but this was incorrect as the reversals were practically 180 deg. It was therefore fair to assume that this type of turbine will absorb practically double the amount of energy per reversal, compared with the Curtis.

Secondly, in the Riedler-Stumpf type, as the author states, the action is complex. This should not condemn the principle but on the other hand should indicate that even better efficiencies with this type are possible when the action is better understood. The Curtis principle has been highly developed, whereas the Riedler-Stumpf has not to date been given serious attention.

The author's statement that the Terry Company has recently developed Curtis machines would seem to indicate that they are abandoning the original Terry machine, whereas, as the writer understands it, the Terry machine is still used on small sizes while the Curtis principle is used for larger or condensing turbines only.

In regard to lining up a turbine and its driven members, he thought it was a comparatively easy matter to do this. It is more a question of education than of adapting a design to eliminate this necessity, thereby possibly getting into other troubles. Some difficulty has been experienced because engineers have assumed that it was not necessary to realign units, especially if they came mounted upon a self-contained cast-iron base and were connected by a flexible coupling. Experience has shown that after a turbine is once lined up it will retain its alignment indefinitely, provided, of course, it has a suitable foundation.

The majority of engineers seem to agree that it is more desirable to have any piece of high-speed apparatus mounted between two substantial bearings than it is to have it overhung. There is no doubt, however, that the latter is cheaper, lighter and occupies less space. The primary consideration in machinery for auxiliary service is, however, reliability, and experience has shown that overhung elements are more sensitive to trouble than those supported between two bearings.

He considered the author's Suggested Code of Practice advantageous not only to the manufacturers but also the ultimate users, but he agreed that in order to apply the idea everyone must adopt and adhere to it.

A. G. Christie took a different view of efficiency to that presented by the author, though he admitted his view might not be consistent with commercial considerations. He wrote:

"This war is bringing home most emphatically to our American people the need of economy. To the engineer this means getting the greatest number of B.t.u. in useful work from each pound of coal burned. The days of cheap coal are fast passing, and with every dollar added to the cost of a ton of coal, the gain from the use of economizers increases. Hence, great impetus will be given to the installation of such equipment and to water-treating systems which will ensure economical operation of such economizers.

"Now, with economizers in a plant, the feedwater need be heated only to 100 instead of 210 deg. fahr. where feedwater heating by exhaust steam is now used. Hence, under such conditions less exhaust steam will be required; and when steam-driven auxiliaries are preferred to motor-driven units, their economy will be closely scrutinized. It may then be desirable to pay a little more for the more economical turbine auxiliary.

"Improvement of design is not wholly inconsistent with decreased cost of manufacture. In fact we have reason to expect our designers to improve their designs with increased knowledge of steam performance and blade materials and at the same time to cheapen their product.

"The small steam turbine usually employed in driving auxiliary machinery does not require much attention as a rule. It would therefore seem that the class of labor employed in looking after auxiliaries should not be a prime consideration in determining the efficiency of the turbine, as Mr. London would lead us to believe. Still, Mr. London is quite correct in insisting on simplicity and durability."

He said that the author's discussion of alignment is very timely and deals with a point that has been a source of great annoyance to purchasers of small turbines. It is to be hoped that manufacturers will take steps at once to finally overcome these difficulties, particularly in those cases where all equipment is not supplied by one party.

He agreed with Mr. London in regard to the unreasonable demands by some engineers for numerous guarantees on each small unit that they buy. He had often felt that these men lacked data in regard to turbine performance. The demands of engineers for guarantees would be simplified if manufacturers would loosen up on this data and let engineers become better acquainted with turbine performance under varying steam and back-pressure conditions and speeds.

Mr. London argued very vigorously for standard ratings of turbines. On a previous occasion, he had urged before the Society the desirability of fixing certain standards for rating steam turbines. It would be most desirable to decide whether the normal rating should be at maximum load or at some percentage of that load. He proposed to bring this matter before the Power Test Committee at its forthcoming meeting.

J. L. Moore, also in a written discussion, considered the author's classification of the present Kerr "Economy" turbine as an original type as misleading, since this turbine is of the Rateau type, consisting of a series of single-pressure stages. The original Kerr machine, designed by Mr. C. V. Kerr in 1904, was a multi-stage turbine, consisting of a series of single-pressure stages with a steam Pelton wheel in each stage. This turbine is no longer built, having been abandoned in favor of the Kerr "Economy" type, designed by himself about ten years ago. This turbine consists of a series of single-pressure stages, each stage having a set of nozzles and a single wheel; it is therefore of the Rateau type.

The author's statement that the Moore turbine is a modified

design of the Kerr is also erroneous and misleading, for the reason that the Moore single-stage turbine is of the Curtis type, while the multi-stage machine is of the Curtis-Rateau type. The mechanical details of the casing of the Moore multi-stage turbine are radically different from the Kerr Economy turbine.

The Terry is an original type, unless the Stumpf may have been designed previous to it. The Westinghouse single-stage type as built in small sizes is also an original type and was, he believed, designed by Mr. R. N. Ehrhart about fifteen years ago.

M. Nusim wrote that turbine development and progress have been very largely influenced by a demand for higher efficiencies, and this is also true so far as small units are concerned.

The Curtis-Rateau turbine, a composite type consisting of a first-stage wheel having two moving rows of buckets followed by a number of stages having a single bucket row per wheel, has been adopted very extensively for large units of all sizes, but by a proper selection of speed it is also being applied for sizes below 1000 hp. for either condensing or non-condensing turbines. This proper selection of speed is often accomplished by the use of reduction gearing so that standard speeds for modern units of capacities below 1000 hp. vary between 5000 and 7000 r.p.m., depending on size. With such speeds, and also with a proper selection of the number of stages, steam economies are possible with small units which were formerly obtained only with large turbines.

J. A. MacMurchy[1] contributed an extensive written discussion of a number of points in the paper. In many cases he agreed with the author, and his statements were in amplification rather than in criticism of those of the author. The following paragraphs are confined in the main to this writer's criticism, as being more significant in the present connection:

"Even more important than simplicity and durability of auxiliary apparatus is the question of reliability in operation. It is absolutely imperative that the turbines driving auxiliaries shall be such that there will be no question whatever of their operating continuously. Both simplicity and reliability of operation are vastly more important than high thermal efficiency, but a skilful designer should be able to obtain the necessary simplicity and reliability, and at the same time a very high efficiency. Efficiency and reliability are not by any means incompatible.

"The author states that forced lubrication is impracticable in small machines for general auxiliary purposes. This has not been my experience, and in later designs the firm with which I am connected is arranging to provide oil pumps for every size of turbine except on a few extremely small lighting sets where ball bearings are used. This adds slightly to the initial cost of the turbine, but the advantages fully justify the expenditure. Even in quite small turbines a small and very simple oil cooler is also justified.

"The author has not sufficiently emphasized the necessity of the governor being relatively very powerful, that is, for a given percentage of speed variation it should exert strong pull on the valve stem. The governor being such an extremely important element, it should receive the same ample lubrication as that provided for the bearings.

"We do not believe there is such a thing as a flexible coupling for high-speed apparatus. Some couplings are of course better than others, but my experience is that it is better to design the machine so that flexible couplings will not be necessary.

"The shafts of the ordinary pump and blower are much too light for direct connection to a turbine to form a two-bearing unit. In many cases the critical speed will be found to be below the running speed, and often so near the running speed as to cause trouble. In geared sets this is quite permissible because of the slow speeds at which the pumps and blowers usually run, and the greater ruggedness of the apparatus.

"The author expresses the opinion that the usual speed-variation requirements are too exacting, and while regulation within 2 per cent is obtainable with entire stability and no tendency to hunt, at the same time there is no necessity for so close regulation; and, in fact, in most cases it is quite undesirable.

"The author discusses the advisability of adoption of a maximum-rating standard. The purchaser, in ordering a turbine, should specify the steam pressure available at the throttle and the power required. The manufacturer should not be required to estimate how much this should be deviated from, and if he furnishes a turbine which meets contract conditions, it should be considered satisfactory."

"It is recommended that the machine be considered as having met its guarantees if the steam consumption on test be within 5 per cent of the guaranteed figures. I am at a loss to understand what possible advantage there can be in this 5 per cent leeway. With a clause of this kind in the specifications, bidders would merely deduct 5 per cent from their expected performance, and nobody is deceived except possibly the purchaser. It would be very much better to hold the manufacturers to specific water rates, and expect the manufacturer to have sufficient margin in his guarantees to take care of the variations in machines.

"The author recommends that oil rings be furnished on machines designed for forced lubrication. I can see no possible advantage in this requirement, and these bearings can be made much better if they are not complicated with oil rings."

Herbert B. Reynolds wrote that the author states that high thermal efficiency is unnecessary in the small turbine if all the exhaust steam is used. This is true if the exhaust steam is used for heating or in manufacturing processes where any deficiency in the exhaust steam would have to be made up by the use of live steam. However, in the case of a power station where the exhaust steam from the auxiliary turbines is used for heating the feedwater, the steam consumption of the small turbines plays an important part in the efficiency of the power station. It is true that the feedwater heater recovers all of the heat in the exhaust steam, but it does not recover the boiler losses which are incurred during the generation of the steam.

C. P. Crissey contributed a comprehensive written discussion in which he said that there is no doubt that in many cases needlessly severe guarantees are requested by purchasers of small turbines, and that the author has done a service in bringing this to general attention.

Any code of practice to be successful must first provide that the turbine meet the requirements of service, and not be primarily for the convenience of the manufacturer.

Regarding steam consumption, as a rule one guarantee point is sufficient; that is, the ultimate operator is fully protected by a guarantee at a single load, one speed and the given steam and exhaust conditions. If other load points are required they should not go below one-half load; quarter-load guarantees should not be required.

When guarantees are given on a condensing turbine, they should not be asked for under non-condensing conditions.

The purchaser is justified in requiring that certain loads be developed under abnormal conditions which are bound to occur. For instance, the author states that the output is reduced about

[1] Pittsburgh, Pa.

20 per cent when the steam pressure drops 10 lb., with an increase of 2 per cent moisture and a rise of 2 lb. back pressure. An experienced purchaser will state the load required and the average conditions of operation at which an economy guarantee is desired, and then specify that the load shall be carried at somewhat poorer conditions which he foresees are liable to occur in ordinary operation. If the purchaser is inexperienced the code should protect him by specifying that the maximum load must be developed if the steam pressure drops a certain percentage, this drop being sufficient to allow for a change in quality or reasonable change in exhaust condition. To meet this requirement the turbine should be supplied with a hand valve opening additional nozzle sections, which, when open, are under control of the valve gear. The cost of the addition is well worth while as a simple matter of insurance.

While economy guarantees on a condensing turbine operating non-condensing should not be required, it is quite reasonable in some instances to demand that a certain fraction of the rated output be developed non-condensing, the purchaser bearing in mind that the demand should not be greater than necessary to safeguard the actual operation of his plant.

It would also be well for a code to prohibit bearing temperatures of 250 deg. fahr.

There is absolutely no reason why the power requirements of pumps and blowers should not be known just as accurately as the outputs of turbines, and they are so known in properly conducted organizations.

It is quite possible to obtain satisfactory operation with a two-bearing unit having a small overhung turbine wheel, but it is a type which, in the nature of things, should be built by manufacturers of combined units. The case is entirely similar to the rigid frame and three-bearing units commended by Mr. London when both parts of the unit are built in one shop. When built by different parties the proposition is, as he says, entirely different. Whether the driven machine is generator, blower or pump, if trouble develops, neither one of the manufacturers or an arbitrator can determine at which door the fault lies.

There are very good reasons why units having four bearings and a coupling have not been more generally superseded by two- or three-bearing sets. This is best illustrated by turbine-driven pumps. In this case a multiplicity of pumps must be driven by a given size of turbine, and on the other hand a certain size of pump must be capable of being driven by several sizes of turbines to meet the demands of various services and customer's requirements. In many cases where economy is of prime importance gears must be interposed between the turbine and pump. It is therefore apparent that an overhung turbine with two bearings or a three-bearing set is an obstruction to producing sets upon a manufacturing basis. Practically every set is a new design that requires careful calculation to prevent trouble from critical speeds or deflection of the wheel which will cause rubbing of the buckets. All this is true when both machines are produced in the same shop. If manufactured in different shops, lengthy correspondence is required to determine whether the pump manufacturer can increase the size of shaft through impellers and bearings to carry a heavier turbine wheel, etc. As no customer is going to wait upon such determinations, it follows that the average agent and some manufacturers will take a chance, with the result that the customer receives an untried and, in many cases, thoroughly unsatisfactory unit.

Customers should guard themselves against two- or three-bearing units that have not been operated with the same distances between bearings, the same diameter of shaft and the same loads upon the shaft, especially when the responsibility is divided between two manufacturers.

The author replied to Mr. Bentley that the relative angle of the steam on the wheel of the Terry type was not 180 deg. He indicated on the blackboard just what the angle was.

Replying to the discussions upon lining up units, he said that two or three pump manufacturers he had talked to had stated that "of the troubles reported in our plants, 90 per cent were directly or indirectly due to faulty lining up of the machine." He considered this matter of lining up a serious proposition.

Mr. Nusim brought up the question of consumption and cost. The water rate has a direct bearing on the cost, and it is a question whether it is more economical to pay for the most highly efficient machine or a cheaper machine. Small turbines can be made much more efficient if the customer will pay the price.

In reply to Mr. MacMurchy he said that adding an overhung rotor puts up the critical speed of the combination.

A five per cent variation in the guarantee would save a lot of trouble. In Europe it is standard practice, even in the larger machines, that all guarantees are accepted or rejected on the basis of 2 per cent either way.

He thought that forced-feed lubrication is an additional complication to be avoided on small turbines. On the other hand, oil rings are a good thing, because with them you are sure of getting oil in the bearings, and they guarantee a supply of oil to the machine in starting up.

Preventable Waste of Coal in the United States, by David Moffat Myers

In the second paper of the session, David Moffat Myers endeavored to show how, by employing proper operating methods in boiler plants, it is easily possible to save at least 10 per cent of the coal now burned for steam-making purposes. Such a saving would release cars for other service equivalent, say, to the coal-carrying capacity of the Pennsylvania Railroad lines east of Pittsburgh, equal to 1,000,000 fifty-ton carloads per year, and the direct money saving to the industries would be around a quarter of a billion dollars, figuring the coal at $5 a ton.

The author stated that the object of the paper was to open a discussion which, he hoped, would lead to the formulation by the Society of definite recommendations of means for the reduction of the present great preventable waste of fuel in our industries, largely through faulty, careless and uninformed operation of boiler plants, and to the offering of the services of the Society to the Government for the organization, furthering, and, as far as possible, execution of the plan which may as a consequence be adopted.

He presented two plans which he thought worthy of consideration. "The one might be termed the autocratic method. This would involve the use of authority to compel coal consumers to execute such measures of economy as the proper authorities might prescribe for any given case, limits to be set as to expense to the user. Such limits might be in terms of a percentage of his present yearly coal bill. Alterations should be directed chiefly to purely operating improvements. Many objections would probably be made by consumers against this plan, but once in effect the majority would no doubt realize its pecuniary advantage to themselves. But its tendency might be too strongly opposed to democratic principles.

"The other plan would be largely an educational one, in which patriotism and efficiency would furnish the motive forces required. The teaching must be accomplished with the

utmost simplicity and directness. This is a big task, but with the technical and executive ability represented in this Society, these things may be accomplished.

"The requisite information much reach the owners and managers of industries, and there must be simple instruction sheets for the engineers and firemen. The vital importance of daily accurate records of coal and water must be taught and information given regarding practical appliances for automatic measurements of both.

"Blank forms might be sent in advance to plant owners in order to be advised by them, first, whether they would be willing to coöperate with a governmental organization offering to assist them in reducing their coal consumption, and second, to obtain such data as to size, type, equipment, operation and fuel consumption of the plants as would enable a classification which would permit a Government board of experts to send such instructions as would include the information needed for any one class of plants."

It is significant that in all the voluminous discussion which this paper brought out, there was practically no disagreement whatever with the author's statements in regard to the waste of coal. Seemingly, almost everyone took these statements for granted, and the trend of the discussion was to emphasize the need of either the author's "autocratic" or "educational" methods of saving coal, or else to describe some other plans for accomplishing the same end. Many of the discussers gave examples of how they had secured results in particular cases, contributory to the one great result desired by all—saving the ten per cent of our coal used for steam making, which, in turn, is two-thirds of our total production.

Walter N. Polakov wrote that of the author's two plans the first one is so unfortunately worded as to create prejudice against it. It reads ". . . the use of authority to compel coal consumers to execute such measures of economy as the proper authority might prescribe in any given case." The plan really means *the abolition of privilege to waste fuel in inefficiently conducted plants, by giving priority in coal deliveries to those who prove that they do use it efficiently.*

This priority can be determined by:

1 Rating by experts (nominated by the national engineering societies and supported by public opinion and the Government) of plants in the indispensable industries which are entitled, because of coal-saving methods in use, to priority in coal supply.

2 Receiving of applications by a special service bureau of The American Society of Mechanical Engineers, from the low-rated plants for assigning the expert help.

3 Serving the needs of such inefficient plants by offering services of recognized experts in power-plant management for direction of the work.

4 Organizing a staff of steam, electrical and combustion engineers, whose members will be assigned to carry out the work in the plants of the applicants under the direction and supervision of experts.

5 Charging for such services an adequate compensation to cover the expenses involved (salaries, traveling and office) but no profit.

Mr. Myers's second plan, "an educational one, in which patriotism and efficiency would furnish the motive forces required," Mr. Polakov thought, is doomed to failure for the following reasons:

a Teaching efficiency by a correspondence-school method will accomplish little good, is incompatible with the professional dignity of this Society and lacks the personal touch.

b Endless variety of equipment, grades of fuel available, personality of men, nature of load, climatic conditions, etc., make the preparation of "simple instruction sheets for engineers and firemen" impossible, and if these are made they are so general as to be useless.

c No instructions of real value could be given unless examination of the plant was made.

d Keeping records, logs, etc., necessitates instrument equipment and measuring devices. All of this is good only when the data are used and interpreted by a trained man and this is done continually. Too many plants have no instruments at all; most of those that have keep them as ornaments due to the lack of proper organization.

e If the regular employees failed to secure high efficiency it is not because of the lack of "circularized education" but chiefly on account of 1, lack of time to carry out investigations and tests, all the time being absorbed by routine duties; 2, absence of instruments, facilities or encouragement; 3, lack of experience in this highly specialized line of research work.

f The education should begin with the owners and managers, not with the firemen.

g The very principle of "teaching" and "instructions" given to manufacturers and plant owners by the Society is undemocratic and un-American. They do not want or need to get something for nothing. Producing for the country but not without profit, they can prefer to pay for what they get if the benefit is commensurate with the expense.

h "Educational" talks and circulars usually degenerate into debating societies wasting time needed for deeds.

i Any half-measures with good intentions falling short of accomplishing valuable results are dangerous, as they chloroform the public conscience.

To sum up, the problem is to be solved by groups and individuals available through this Society for the service of those who know that more power can be gotten out of a pound of coal. There is no necessity of compelling plant owners to improve their methods, since in such a step lies their self-preservation. But there is an urgent necessity from the national standpoint to conserve the fuel by preventing its waste by ignorance or indifference. The valuation of plant methods to establish ratings for priority in coal deliveries is therefore recommended.

Percival R. Moses,[1] in a written discussion sent in subsequent to the meeting, described still another method whereby a saving in the amount of fuel burned may be obtained, greatly in excess of that which may be obtained by improvement of the individual plant. Broadly put, the saving would be effected by shutting down the inefficient plant and obtaining the power supplied from such plants from an efficient source.

Emmett B. Carter agreed with Mr. Myers's idea of a campaign of education among the firemen, but thought that we should feel some hesitancy in recommending the establishment of a bureau of such magnitude as would be required to carry on the work proposed, because we lack the men. The bureau will mean a very large force of men, valuable technical men, who can ill be spared now from other important work.

It is this same lack of intelligent men which is causing the waste of so much of our coal in the first place. Almost one-half of the coal being consumed for steam is used by the railroads, and the great problem confronting the railroads now is not how to burn the coal economically, but how to get the men to burn the coal at all.

[1] 366 Fifth Ave., N. Y.

C. R. Weymouth wrote that in his opinion the possible saving in coal consumption due to increased boiler efficiency would be materially less than stated by Mr. Myers. The biggest coal users of today were the mammoth public-utility companies, who had already been compelled to employ the best brains available and boiler-room efficiency engineers as well to maintain their economy of power production at a maximum, and it was inconceivable to him that they could save 10 per cent in their fuel consumption, or even half of that amount. There were no doubt many smaller users of power where the yearly bill was such that they were not warranted in employing an efficiency engineer, and in these plants a saving would be possible if expert service were available.

Mr. Weymouth suggested the formation of a committee of engineers representing the various classes of coal users, and familiar with this subject, to make a preliminary canvass of the situation from the data available, including census reports. The findings of this committee would indicate the extent to which this subject should be further investigated and recommendations made to the Federal Fuel Administrator. This investigation should also cover the question of availability of engineers and fuel experts to give instructions as to the better firing methods, should it be found that a large fuel saving is possible. His observations indicated that nearly all mechanical engineers are busy in some department or other in connection with the war, or vital industries, and that comparatively few men will be available to carry on a fuel-saving compaign, even should it be found that such a campaign might give beneficial results.

Whether the committee's findings indicate that a large fuel saving could be made, all engineers will agree that a campaign of some character should be made to reduce the waste of coal. Mr. Myers's suggestion that instructions be issued to firemen in simple language is a very timely one. We have had textbooks and technical papers almost without limit prepared for the benefit of technically trained men; but there has never been, to his knowledge, a suitable primer giving the elementary principles of combustion and the essential knowledge for a fireman. The preparation of such a primer could be well undertaken by the committee proposed, and it could be given wide circulation with surely beneficial results.

Any attempt to curtail the coal supply as a means of compulsory increase in boiler efficiency would, to his mind, lead to a chaotic condition. Whatever is done must be done voluntarily, at least initially. Variations in load factor, rate of demand, etc., complications of red tape, are such that any limitation of the quantity of coal supplied a given user would likely give rise to regrettable complications and curtailment of necessary output.

While there are minor improvements in boiler plants which can be made at this time, it must be borne in mind that the present-day trend in increased economy of fuel calls for higher steam pressures, higher degrees of superheat, larger prime movers, centralized generating stations—things which, if now generally put into effect, would immediately tax certain manufacturing facilities which should be left undisturbed for the production of the war's necessities.

A. F. Graves[1] gave an interesting example of what could be done in a specific plant, even in one which had always taken pride in boiler-room economy.

An instrument board was installed in the boiler room, with water- and steam-flow meters, temperature recorders and draft gages. With this means of studying all conditions, series of tests were run on the boilers for the purpose of finding the most efficient operating conditions at all loads, and printed instructions issued to the firemen so that they could always maintain these conditions. By this means a saving of about 12 per cent of the coal bill has been made. Possibly some ammunition factory is using that very coal to make the rifles that will help to put "our boys" over the top.

All lines of manufacturing must be kept moving, and with the present car shortage, the *knowing how* to prevent waste of coal would do much to keep up the supply.

It seems only fair to rate a plant for its wastefulness as well as its economy, and that the plant which can burn the coal most efficiently should have priority in coal deliveries.

[1] Strathmore Paper Co., Mittineague, Mass.

R. K. Goodlatte[1] expressed as his written opinion that great good would be accomplished if the Society, backed by the Fuel Administration Board, would inaugurate an active campaign toward the end of preventing waste in industrial plants.

He suggested publishing posters giving simple instructions for hand and stoker firing, cleaning of fires, watching scale prevention, coal weighing, water measuring, etc. These instructions could be made vital and forceful by periodical visits by practical men with authority to enforce them, if necessary, under threat of coal-supply regulation.

E. P. Roberts suggested two ways of saving fuel—reducing the smoke loss by correct design and operation, remembering that the loss due to smoke from bituminous coal burned in towns and cities is seldom less than $1.50 per ton, and adopting "sensible heating."

Sensible heating is heating that satisfies the senses rather than the dry-bulb thermometer. Sensible heating is paying proper attention to humidity, securing the result of lower thermometer (dry-bulb), greater comfort, better health, lower fuel bill, etc.

Albert A. Cary, in an extensive written discussion, alluded to the author's statement that "The saving or wasting of one-fourth of the coal consumption of any industrial plant depends *entirely* upon the efficiency of its operating management" as the text upon which the balance of his paper is founded. He continued:

"In order to secure the desired conservation of fuels in such plants, Mr. Myers advises the services of the expert in operating management, by compulsion or otherwise; he suggests what Mr. Polakov has aptly termed a correspondence-school course, which, in the light of our experience, is not a wholly worthy suggestion.

"The expert in operating management—provided he is properly qualified and thoroughly understands his business, including the proper handling of the fuel used—can undoubtedly secure very desirable fuel savings; but his efficiency depends very largely upon the coöperation he receives from the plant owners and their employees, as well as their willingness to equip their plant with all the needed apparatus and to maintain and use them continuously after the expert concludes his work.

"Aside from the training of a boiler-room force by such experts, there are other matters which cannot be relegated to a second place of importance in considering the requirements for reducing the waste of fuel.

"Proper furnace design and construction, adapted to the use of the particular kind of quality of fuel used, furnish unquestionably the very keynote of the whole question of fuel conservation. By the term *furnace design* in a boiler equipment is included not only the furnace with its equipment, but

[1] Delawanna, N. J.

also the entire boiler setting, flue and draft-producing equipment.

"Let us concentrate with greater earnestness upon the design and construction of our furnaces. Let us study our available refractories for furnace linings with greater care, as well as the high-temperature cements, the mortar used, and the red bricks used to enclose our settings.

"After equipping our plant with proper furnace settings which are adapted to produce the highest possible efficiency with the particular fuel available, our expert in operating management can come into the plant and do his most efficient work by instructing the men how to operate the furnaces in the most efficient manner. He can train them in the use of the instruments required to keep the plant constantly in its highest operating conditions, and there are many other needed duties requiring his attention to produce the most economical and requisite results which will reduce the amount of fuel and labor required.

"Turning now to the personal factor which enters so strongly into our fuel-economy problem: In our larger central power stations, the men who handle the coal and operate the boilers have been well trained, and they generally know that they *must* obey instructions or lose their jobs. In the smaller plants, we find a wide variety of firemen, some of whom are splendid fellows, who are anxious to learn, and those who take a pride in their work; while others strongly resent the intrusion of an outsider to show them how to operate their plant more economically. This latter class is responsible for the largest wastes of fuel occurring in steam plants.

"Many of these men are certainly not fitted for the position of firemen, and, unfortunately, many employers seem to think that the only qualifications needed are that they be strong, husky men, who can stand up before a hot fire and shovel in a lot of coal every time the furnace door is opened, and then to pull out the ash and clinkers from the grates or ashpit once a day.

"In order to stop our enormous coal wastes in industrial and other plants, these so-called firemen are the first men we should get under control, and, after giving this matter considerable thought, I have reached the conclusion that there is one way in which this can be done practically.

"To meet the present emergency, I propose that the War Coal Board take the necessary measures to bring all the firemen in this country under their control by requiring the firemen to take out and hold a United States license.

"The applicants for these licenses must show some qualifications which would entitle them to hold such privileges, but it is doubtful whether it would be possible, at the beginning, to have all of these applicants examined before qualified examination boards.

"Future applicants should be required to pass an examination before such boards, and qualify in a satisfactory manner before receiving their licenses.

"By this means, a better class of men will gradually displace the many fuel-wasting incompetents who are now disgracing the firemen's trade.

"This process would thus tend to 'weed out' the incompetent men who are keeping good, deserving and competent firemen out of jobs which belong to them, and thus, eventually, the status of the firemen would be raised, and their better fuel-saving work will merit them a higher rate of wages, which the owner can well afford to pay out of such savings effected in his steam plant.

"On the other hand, the stubborn, unpatriotic, penny-wise and pound-foolish owners of coal-burning plants, where glaringly wasteful conditions exist—who refuse to spend a cent to better their conditions and 'do their bit' in the conservation of fuel in this time of need—will meet with a rude awakening, and they will learn a lesson which will ultimately result greatly to their advantage and save them many dollars which would otherwise be hurled up their chimneys.

"This proposed method is now but a war measure, but after the war it is bound to result in a great benefit to the owners of coal-burning plants and to the country at large."

Lewis S. Maxfield suggested that the Government perfect the use of our peat deposits and deliver this fuel to the industries with instructions as to its proper use, instead of trying to make our industries do with less of the very first element of their existence. With the present high cost of labor and materials few power plants are in a position to undertake extensive improvements which would render them more efficient in the use of coal.

We have extensive peat bogs, the amount of combustible matter in which, it is estimated, exceeds that in all our known coal deposits. Peat is being used extensively in Europe as a fuel, and several large industrial plants report satisfactory operation with it.

The most successful method of utilizing peat at present seems to be in the gas producer, which will handle peat with a moisture content of 30 to 35 per cent, which is obtainable by air drying.

He admitted that many difficulties were met with in the use of peat, and as its use extended other problems would come up, but he thought they would be solved as have those incident to the use of coal.

John E. Muhlfeld considered that the autocratic and educational plans of procedure outlined were not in themselves sufficient for the consumers of coal to use as a basis for authorizing the capital expenditures that will, in the majority of cases, have to be made in order to produce the desired results and thereby secure an adequate financial return on the investment to be made.

Furthermore, particular stress should be laid on the fact that the more effective use of fuel should and can be made to bring about improved conditions in plant operation and labor, as well as conservation in fuel and financial returns.

Each power plant is, in itself, an individual engineering problem, and blanket instructions and advices cannot be of the greatest value.

There is no lack of patriotism among the coal users and the engineers of this country, and he doubted if any of them are "selling the United States short," but localized engineering improvements and supervision along practical lines for the purpose of modernizing plant equipment, and its maintenance and operation, are essential for the greatest accomplishment.

The scope of the procedure for the conservation of coal, steam-railway facilities and labor could be materially broadened by including

a The utilization of existing by-products of mining operations that are useful for steam-generating purposes, but which are now being wasted.

b The development and use of vast deposits of sub-bituminous coals and lignites lying adjacent to steam-railway lines.

The fact that one of our allies, Brazil, has recently, through the efforts of its government engineers, made possible the effective and economical use of its native coal, which has heretofore been deemed practically worthless, and thereby diminished its dependence upon imported coal for railway operation and industrial development, is worthy of our serious consideration.

The amount of useful coal now being wasted through existing methods of mining is great enough to more than offset the present shortage, and the reclamation and utilization of this by-product, for which labor, material and plant for mining have already been employed, in conjunction with the development of new sources of coal and lignite supply tributary to the points of consumption, are of paramount importance.

B. G. Elliott described the method employed by the University of Wisconsin to reach the firemen and engineers in power plants by means of lectures, demonstrations, and class-study groups.

The firemen and engineers are organized in a class group and are met each week by a traveling instructor who lectures and demonstrates to them on the various problems connected with the economical combustion of fuel. The class groups usually meet for a period of eight to ten weeks. At the end of the class and lecture work, the members of the class are usually gotten together for a boiler test conducted according to the best modern practice. This test is held at one of the plants of the community, the apparatus and recording devices being sent from the University. The men are required to work up the test on specially prepared forms.

When there has not been a demand for an extended class course, the subject is presented by means of an individual lecture and demonstration on coal, its composition and combustion. The manufacturers and the business men, as well as the firemen, are invited to attend this lecture, which has proved to be a very effective method of bringing the problem before this group of men who are interested more from a financial than from a technical point of view.

Michael M. Podolsky[1] proposed a "coöperative" plan for solving the fuel problem, the plan to be under the control and supervision of the Government, but to be under the management of specialists nominated by the Society in conjunction with the mining, electrical and chemical engineers.

The main feature of his plan was the organization by the fuel consumers of a national society for fuel saving, the work of which would be carried on by each member contributing annually on the basis of, say, 5 to 7 cents per ton of coal consumed.

The functions of this society would be mainly to disseminate information regarding fuel saving, to provide help to the Fuel Administrator, to recommend to the Government steps for relieving and preventing fuel shortage, to investigate and report upon new methods for saving coal, to establish special schools for firemen, to hold exhibitions and give prizes for best inventions and to aid inventors of fuel-saving devices.

The work of such a society would be under the direction of a council and would be carried out under its direction by a manager and staff.

This discusser voiced as his belief that only by the fullest coöperation between the Government, the coal consumers and the engineers on the widest scale could the fuel problem be solved. Notwithstanding the meager development of the coöperative idea in this country, the A.S.M.E. could institute such a coöperative method as described with the greatest practical results. He suggested appointing a committee to consider the plans presented in the paper and discussions and draw up a war plan, perhaps in collaboration with the Federal Fuel Administrator.

William L. Cathcart wrote that the United States is now the leading coal-producing country. Two-thirds of our total production is burned for steam making, with an approximate waste—as Mr. Myers very conservatively estimates—of 10 per cent, through lack of efficiency in the operation of boiler furnaces. That is, with the war industries of our French and Italian allies retarded and their civilian population freezing from lack of coal, we are wasting about 50 million tons a year.

It is a truism to say that this is an engineer's war, and, in many of its most important features, a mechanical engineer's war, both on land and sea. So, for the prevention of this huge waste, this colosssal drain on the war energy of our allies and ourselves, our Government officials may rightfully look to the membership of this Society for information and suggestions leading to a definite remedial plan.

The paper presented by Mr. Myers covers broadly the whole problem of fuel economy, as applied to steam making on land. In the writer's view, a specific program developed from it, and based upon it, is what is needed urgently, not only for the prosecution of our own war aims, but for sorely needed aid to our allies—a need that will increase steadily until victory is won.

It should be noted, too, that the economies produced from the execution of such a program would be *permanent,* lasting after the war, an enforced lesson in the value of fuel economy.

America is not alone in her prodigal waste of fuel. Sydney Brooks says: "There is very good reason, therefore, why Great Britain should observe the utmost care and economy in her methods of getting coal and of using it, and in her management of the entire coal industry. So far, her methods have been those of shiftlessness and improvidence."

But, if Britain can learn, so can we. Our trouble is not unwillingness. It is simply indifference as to the value of fuel economy. And, so far as the adoption of proper remedial measures is concerned—although specifically the user will profit—it is now broadly a question of patriotism, and the managers of our industrial plants will scarcely be lacking in that.

However, there might readily be a fair number of cases in which it would be difficult to secure compliance with a mere official request to adopt methods of fuel economy. Further, the education of firemen alone scarcely seems to be a practicable solution. The pressure on those firemen for that education should come from the owners and managers of their plants. This sort of efficiency grows best from the top down, not from the bottom up.

In the relatively few cases in which it might be necessary to bring pressure on owners or managers, Mr. Myers's comment suggests the necessary "big stick." Let the Government allow them only a quarterly or yearly amount of coal which will produce, when burned with full economy, the number of pounds of steam they require normally. If they choose to waste their allowance, let them shut down until they get their next allowance. The rigid control which the Government is now exercising, through the Federal Trade Commission, on the newsprint industry should be a lesson to such possible recalcitrants. These are war times, not the lax days of peace.

L. P. Breckenridge, Chairman of the Committee of Consulting Engineers on Coal Conservation and Publicity coöperating with the Bureau of Mines and the Federal Fuel Administrator, said that the ideas presented in the paper and discussions were excellent, but the question was whether they were immediately available. We must save coal and save it quickly, and anyone with suggestions should send them to Mr. O. P. Hood, at the U. S. Bureau of Mines, or to himself.

He said that Dr. Garfield, U. S. Fuel Administrator, was now preparing material to send out broadcast emphasizing the very great necessity of saving coal. Engineers should coöpe-

[1] Standard Steel Works Co., Burnham, Pa.

rate in this campaign, preferably through the representative of the Fuel Administrator in each state.

As examples of what could be done in this connection, the engineers of the Experiment Station of the University of Illinois have sent out valuable material regarding the use of the coal consumed largely in Illinois. The Fuel Administrator of Illinois should have the assistance of these men. The engineers in Connecticut, Virginia, Pennsylvania, and other states should similarly coöperate with the fuel administrators of these states, and much good will result.

Wherever engineering societies exist, some plan should be started, with the slogan "help save coal." Get in touch with the state or the city fuel administrator and offer aid. Get Government bulletins from the Bureau of Mines and distribute them at a lecture to "owners, managers and firemen." Help the local papers select facts and help them avoid "fiction." The important thing is to get sound directions to the fellow who is handling the shovel both in the home and in the factory.

Norman G. Reinicker agreed with all that had been said about operation, but considered that the biggest gain was not in operation but in design. Given a plant and the conditions to operate under, the results are probably 85 per cent due to design and 15 per cent to operation. He thought it was unfortunate that we should have reached the stage of having to save coal now, when we might have saved it a long time ago when plants were originally built, by putting in the proper apparatus.

In designing or remodeling a plant we should take into our confidence the manufacturers of the apparatus. They can give very valuable suggestions.

Improvement in designing does not refer alone to coal saving, but also labor saving. If we can build an ashpit that will hold 24 hours' ashes, instead of holding only one dump and requiring a man to be on duty during the whole of the 24 hours to handle the ashes, we can save considerable labor.

Even at the present time we can make our biggest saving, possibly, by changing the apparatus—scrapping some of the old stuff. It is a bad time to do it, of course, because the manufacturers are loaded down with other orders, but we should try to slip in some of these orders for new apparatus from time to time.

Waldron C. Beekley emphasized the extended use of exhaust steam in process heating as a means of fuel conservation. By putting in apparatus to properly use exhaust steam in heating water for various processes, the coal consumption can be reduced 30 per cent.

He noticed in Mr. Myers's paper a suggestion that the Society present some recommendations to the Government in regard to the way in which this fuel problem could be met, and he thought it would be very desirable if the above point could be followed up.

J. S. Lane said that the author's statement: "It is evident that we now require an extension of the idea of education, but in such form as directly to affect the men who run the boiler plants of our country, for in their hands is the saving or wasting of one-fourth of the fuel which they consume," was made just as though these men had the matter all in their hands; and, while it is true they do have a good deal in their hands, yet Mr. Cary hit the nail on the head in wanting the right furnaces and the right apparatus. Even though you teach the average fireman the best ways of firing, when your back is turned he will go back to his old way.

Many boiler plants both small and large are now fitted with appliances that automatically and continuously maintain balanced-draft conditions in the furnace, supplying just the right amount of air required for combustion, maintaining a uniform steam pressure, and allowing the hot gases the longest possible contact with the heating surfaces of the boiler; and a further elimination of the human element can be effected by the use of a mechanical stoker, automatically controlled by the balanced-draft regulator so that the feed of fuel is varied in proportion to the supply of air.

The author also speaks of the railroads, saying "We are now threatened with a serious coal shortage due chiefly to the overstrained carrying capacity of the railroads." It is believed, however, that if the known methods of saving fuel are employed, thus relieving the railroads from carrying some of it and leaving the saved part in the ground for the use of those who are to come afterward instead of burning it all up now, railroads, coal users, and the general public will be benefited.

Edward N. Trump said there was one way of reaching the man who shovels the coal into the furnace which had not been touched on, and that is to make it to his interest to save the coal. He had found in increasing the efficiency of their coal plants from 50 per cent, which they used to consider fairly good, to 85 per cent, a very large part of that increase was produced by making it of interest to the men who did the work to produce these economical results.

If you give a bonus to your fireman, you will be sure to have some result. He had found at least ten per cent saving by paying a bonus to the fireman, and also by working one shift against the other, that is to say, making it to their interest to improve the saving.

Installing such a plan has not proved difficult. If you have the necessary instruments you can, in the first place, determine the amount of carbonic acid in the waste gases. You can measure the water. In addition, you can take samples of the ashes and determine the amount of carbon. If at the end of a month, having these three things, you work out the efficiency from these items, and work each shift, one against the other, you will get results which will be surprising—save at least ten per cent of the fuel with the same apparatus and without any changes whatever.

Combustion is a chemical phenomenon and can be diagnosed and controlled only by chemical means; and you have to have apparatus to do that; and it ought to be so that the fireman can tell instantly, so that it shows right on the front of every boiler, what the condition of his fire is; and that, in addition to all of the other things which have been brought up, will bring the maximum efficiency.

The chairman said there is another phase of this situation, and that is the fact that we are endeavoring to work out a plan by which concrete, nation-wide propaganda can be put into operation, taking into account thousands and thousands of power plants. Furthermore, we have a situation at the present day complicating the normal conditions enormously in that the personnel of our fireroom forces is in a condition of ferment—our manufacturers do not know today how many of the men who are in their plants will be with them tomorrow; and to carry the thing further, they have not the slightest idea as to how many of their trained firemen, and their firemen who know their equipment, they will have two or three months hence. Consequently, we have some added critical and difficult aspects of the subject, but that is no reason why the Society should not do everything in its power to work out the best that can be done in this matter. He was personally inclined to believe that with collective coöperation we ought to

be able to do everything Mr. Myers has said, and possibly do a shade better.

The author in closing the discussion stated that he was surprised that some of the discussers did not understand the relation between equipment and operation in their effect upon efficiency. There is a mathematical equation which expresses this relation, which is as follows: Efficiency in any process is equal to the efficiency of the mechanical equipment multiplied by the efficiency of the human factor. This may be expressed: Efficiency equals $E \times H$. For example, in the matter of fuel economy, if we have a furnace perfectly designed and adapted for a specified fuel and purpose, we may regard our equipment as having an efficiency of 100 per cent, but if the man who operates the furnace is drunk, the efficiency of the operation will be zero.

Take it the other way around, and suppose we have a perfect fireman but the grate has fallen out of the furnace; our efficiency will again be zero. Thus, as stated, the formula $E \times H$ truly expresses the relation between equipment and operation in determining the efficiency of any process.

Consequently we must of course endeavor to obtain the highest attainable efficiency both of equipment and of operation, in order to realize the maximum of combined or ultimate efficiency.

The point of all this is that by improving the efficiency of operation alone, the combined efficiency is susceptible of great and immediate improvement. Without loss of time and without expenditure for new or changed equipment, an average saving of 10 to 20 per cent of coal can be effected in factory boiler plants. Therefore, in a fuel-saving campaign, adequate measures must be directed first toward obtaining the maximum improvement possible in the way of purely operating economies. Later, the equipment side of the proposition should be given urgent attention.

The immediate problem before us is to develop ways and means for putting into effect these economies which I have shown may equal 50 million to 100 million tons of coal saved per year. These savings may go into effect at once.

I regret that the greatest volume of discussion on my paper has been directed toward technicalities. All competent engineers who have studied the fuel problem know the technical side of the situation, and if I had been allowed the time and space, I could have presented all of the technical information and suggestions which have been involved in this discussion. All good fuel engineers know these things; the bad ones do not count.

The present situation does not call for technical discussion, but it does call for *ways and means* for putting into effect the knowledge which we now have and in such a manner as to save the 50 million to 100 million tons of coal per year which can be saved. A few very interesting suggestions on ways and means have been brought forward in the discussion.

Let me first state most emphatically that education will comprise an essential feature in the campaign for saving coal which will be adopted and successfully prosecuted in this country: education of the owner, education of the firemen.

Incentive must be added to education so that manufacturers and owners will *desire* to coöperate in the fuel-saving campaign. It is probable that for the most part patriotism and efficiency will provide sufficient incentive, but to this may be added the shutting-down of inefficient plants in case of necessity. It would not be fair to the highly efficient plants to cut off their coal supply while wasteful plants were literally throwing away coal. The whole question resolves itself into that of ways and means for executing the measures of economy which all fuel engineers know are necessary at this time. It is desirable to work as far as possible through existing agencies and organizations. For instance, the federal, state and local chambers of commerce are already working along these lines to some extent and they should be encouraged and helped from headquarters by bulletins on fuel economy, the furnishing of lecturers, starting of schools for firemen, etc. Then the manufacturers' associations will be of very great value. They should be urged to pledge themselves to a campaign of fuel economy in their respective localities. They should get together for meetings devoted to the subject; they should obtain the best fuel engineers in their vicinity to lecture to them; they should get the services of these men to visit their plants and make suggestions and adopt further sensible plans for saving fuel.

Any plant owner who failed actively to install methods for economizing in the use of fuel in his plant would be considered a bad citizen by the other members of his association who would be working for governmental interests. This bad citizen would be made to feel the displeasure of his neighbors and would probably take heed and give attention to his own plant. If this did not work, then the Government could compel him to bring his plant up to a suitable degree of efficiency or limit his coal supply.

Mr. Podolsky in his discussion, made a suggestion along these general lines in which he suggested a national society for fuel saving. The local manufacturers' association to which I have alluded, could, if found desirable, be combined to form such a national society or association. This constitutes one of the most valuable suggestions that has been made in the discussion.

While our problem relates principally to fuel saving, labor saving is also important. Mr. Reinicker has brought out this feature in a limited way in his suggestion regarding an ashpit to hold 24 hours' accumulation. Of course this phase of the subject could be developed indefinitely, but this is aside from the present object. Mr. Reinicker, however, is wrong in his statement that "the results are probably 85 per cent due to design and 15 per cent to operation." As I demonstrated in the first part of my discussion, the combined efficiency is equal to the efficiency of the equipment multiplied by the efficiency of operation, and in my own practice I have found that in most factory plants a saving of 10 to 25 per cent can be made by modification of operating methods alone. I can quote cases where improvement has been as high as 50 per cent. Further savings, depending upon the original design of the plant, can be made by suitable changes in the equipment.

Mr. Beckley brings out the fact that there is a large saving to be made by the utilization of exhaust steam. This point was brought out in my paper in Par. 23. The actual saving, however, in case all the exhaust from an ordinary factory engine is utilized would approximate 90 per cent instead of the 30 per cent which Mr. Beckley quotes. (See my paper entitled The Heating Value of Exhaust Steam, presented at the annual meeting of the American Society of Heating and Ventilating Engineers in January 1915, in which I gave a formula for determining the heat value of exhaust steam from any engine, pump or turbine. In this paper are given curves from which the heat value of exhaust is determined graphically).

Mr. Trump's discussion is extremely valuable as he is bringing out the new idea in boiler-room management of giving the firemen an interest in the coal which they are able to save by intelligent effort. The statement which he has made should be convincing since it is based on actual experience in his own large plants. I have designed bonus systems for many plants

in this country. The reason that many bonus systems have failed is that they have not been suited to the particular case and local conditions for which they are supposed to be designed. But the bonus system will be increasingly used in this country during the coming years in connection with boiler-house accounting systems. Every plant in the country which burns as much as five tons of coal per day should have some kind of an accounting system to indicate at least approximately the efficiency of the boilers and furnaces. The best system is continuous weighing of coal and water by modern methods supplemented by ue-gas analysis. But where this complete system cannot be installed for practical reasons, a flue-gas-analysis system can be and should be installed. The United States Fuel Administration should endorse this specific measure in formulating a program to be sent out through the State Fuel Administrators to the industries.

Mr. Polakov speaks slightingly of what he is pleased to term "by correspondence-school methods." I did not suggest correspondence-school methods but I did suggest education by every possible means, both by personal teaching and by bulletins and circulars prepared specifically for definite purposes. Mr. Polakov's method is quite suitable for private consulting practice such as his or mine, and I follow his thorough methods in my own practice. But Mr. Polakov has evidently not considered the difference between a private practice and a national practice. For instance, were we to carry out Mr. Polakov's idea it would require four thousand Mr. Polakovs working eighteen months at a cost to the Government of $36,000,000 to make an inspection of three or four days in each industrial plant in the country. In the first place, we have not got four thousand Polakovs, neither can we wait eighteen months, and $36,000,000 is too much to pay for it. His plan is impracticable when it comes to a large-scale proposition.

What we require at the present time is a constructive policy and program which must be taken up by the United States Fuel Administration in a comprehensive manner. The plan must involve all the elements which I have suggested and there is no doubt but what such a plan will be formulated and adopted with large results. The 50,000,000 to 100,000,000 tons of coal a year can be saved and must be saved.

Bagasse as a Source of Fuel, by E. C. Freeland

This paper was awarded Honorable Mention in the Student Prize Contest, 1917, and was included in the Power-Plant Session because of its connection with the fuel problem to which Mr. Myers's paper was devoted.

In it the author discussed the nature and value of bagasse as a fuel, and described methods for calculating its fuel value, methods used in drying and boiler furnaces for burning bagasse.

He said that the heating value of a pound of average dry Louisiana bagasse is found by experiment to be 8300 B.t.u., and despite a high moisture content of about 50 per cent it is therefore a valuable fuel. While in former years not much attention was paid to the drying of bagasse before burning it, many authorities now claim that a great saving can be effected by such procedure.

David Moffat Myers, in an extended written discussion, said that his most recent experience in connection with bagasse burning occurred during seven weeks in Cuba last winter, where he was retained to investigate and report upon the conditions of boiler-plant economy in six sugar mills. He submitted the following observations relating in particular to his investigation of a mill in the eastern part of the island, near Manzanillo Bay, with a capacity of 3750 tons per 24 hours.

In this section of the island the fiber content of the cane is only about 10 per cent, whereas in some other parts it runs as high as 12 per cent, thus giving in the latter a bagasse of greater heating value, while the mill requirements for steam are less owing to the lesser quantity of juice extracted. Consequently, the mill supplied with cane of the higher fiber content has a great advantage in respect to economy in the use of auxiliary fuel.

In Cuba, in a perfectly designed and properly balanced sugar mill, i.e., where the exhaust steam produced is no greater than the demand for it, and where all the condensation from modern multiple-effect evaporators is returned to the boilers, the by-product bagasse is sufficient to supply all the steam when all departments of the plant are working in harmony. But where these conditions do not obtain, and there are numerous examples, auxiliary fuel in the form of wood, oil or coal must be burned.

In Cuba, wood is the most common auxiliary fuel and the cheapest in cost per million B.t.u., although the connected labor is greater than with either of the other fuels.

There is no trouble whatever in obtaining a very high-grade combustion with bagasse, even with very crude methods and furnaces. When the supply of bagasse was coming regularly and no wood was used in the furnaces, the CO_2 ranged from 10 to over 17 per cent. When wood was fired in with the bagasse, especially by some of the methods commonly employed, the furnace efficiency was immediately reduced to a degree indicated by a CO_2 content of from 3 to 6 per cent.

By changing the method of firing the wood with certain furnace alterations, a great improvement was obtained both in more uniform steam pressure and in a substantial reduction of the amount of auxiliary fuel required.

From the standpoint of the mill owner the cost of the auxiliary wood fuel—formerly about $300 per day—was a matter of only secondary importance. But the difficulty in maintaining uniform working steam pressure was of vital importance, since the inability to do so was reducing the normal capacity of the mill by an amount of grinding equivalent to $500,000 per year in output of sugar.

Stated briefly, the causes for this loss due to inability to hold steam were as follows:

1 Irregularity in feeding the furnaces, due largely to ignorant labor without white-man supervision. Supervision was installed and a large improvement immediately effected.

2 Wrong method of firing wood with furnaces ill-adapted to the purpose. This was corrected and furnaces improved, with an additional improvement in steam pressure and substantial reduction in auxiliary fuel.

3 Draft regulation entirely wrong. Plan was prepared for convenient regulation by uptake dampers to control fires and steam production.

4 Grate surfaces with natural draft burned 300 lb. bagasse per sq. ft. per hour when clean after Sunday shutdown, but clinker on furnace walls grew so rapidly that by the middle of the week the grate area would become so restricted that the capacity of the boilers was seriously reduced and formed a chief factor in the inability to hold steam. This trouble was corrected in the new furnaces designed and installed by the writer by using larger grate surface. This resulted in ability to obtain boiler capacity at all times.

5 Owing to the surplus of exhaust steam in this badly balanced plant and to other causes relating to the design and

operation of the whole mill, sufficient condensation was not available for boiler feed. Consequently, raw water had to be used as a make-up supply. This water was from wells, and its analysis showed it to be of the most detrimental character for boiler feed that the writer had ever found. The boilers, as a consequenuce, were covered with heavy scale, pitted badly and were constantly springing leaks.

The effect on fuel economy and steam production need hardly be described.

The remedy recommended was a lime-soda process of purification, filtration and storage for the raw water, and this system has been specified, purchased, and will soon be installed.

Other changes were recommended and are being installed, and there is no doubt that when the improvements are all in effect the production saving of about half a million dollars per year will be accomplished.

In further regard to the combustion of bagasse, there is one point that is likely to be overlooked unless the combustion engineer is familiar with the operation of sugar mills. A bagasse-burning boiler plant is subject to a very critical disadvantage not imposed on any other kind of a boiler plant. There is no storage supply of fuel *at the furnaces* available for instant use when occasion demands. When the boiler pressure begins to drop rapidly, the natural method employed in coal-fired steam plants is to increase at once the feeding of the fuel and the supply of air to the furnaces. This method is not applicable with the usual design of sugar-mill boiler-house equipment. The bagasse carriers keep an approximately uniform stream of the fuel moving along over the furnace tops as the mills supply it, and it is fed directly from the carriers through adjustable gates and feeders to the furnaces. Any surplus bagasse travels to the end of the conveyor, where it discharges in a pile on the ground. This pile forms the only available storage of fuel.

Consequently, when a shortage occurs or when additional steam is quickly drawn from the boilers, there is no adequate method of meeting the emergency. The result is apt to be a serious drop in steam pressure, causing longer cut-off of mill engines and a further increase in the demand for steam. The excessive time required to pitch from the surplus pile into the conveyors, added to the time consumed by the travel of this bagasse to the furnaces, renders this method of storage of little or no avail. Therefore, unless auxiliary fuel, such as oil or coal, is immediately fired as the steam pressure begins to fall, the effect is so bad that at times it becomes necessary to shut down the mills to raise steam to working pressure.

This problem, it is believed, is more important than that of drying the bagasse, which must necessitate a complication of plant not desirable under the difficult conditions of ignorant labor which must be depended upon in Cuba.

In fact, the problem of bagasse burning cannot successfully be considered merely as a combustion problem, although, of course, that forms one of the factors. But other factors enter more importantly in an efficiently operated sugar mill. Some of these have been touched upon (in the beginning of this discussion), and they include considerations relating particularly to the scientific design of the whole mill combined with its operation.

If there is trouble and delay at the mills, the bagasse supply is interrupted and the best furnace design is of no avail; unless intelligent supervision of the regulation of bagasse feeding and of dampers and cleaning of fires is provided, scientific boiler and furnace equipment helps but little; if a shutdown occurs at the evaporators, the mills are badly affected.

The matter of boiler efficiency in a sugar mill is inflexibly connected to, and affected by, the operation of the production functions of the entire mill. Consequently, an efficient boiler plant becomes largely a by-product of these other conditions relating to the general management of the mill and the harmonizing and correlating of its functions.

Such very large savings can be accomplished along these lines, given a well-designed boiler plant, that such an apparatus as a bagasse dryer would not generally be favorably regarded by plant owners unless its installation and operation could be effected at low cost and its design were such as to require little or no attention and is virtually fireproof.

In the operation of the plant referred to, upon which Mr. Myers conducted a large number of tests on combustion and evaporation, when the CO_2 ran above 16 per cent there were usually found considerable amounts of CO. In one test for which a heat balance was computed, the CO produced a loss equal to about 12 per cent of the available heat in the bagasse as fired.

The corresponding flue-gas analysis was 14 per cent CO_2, 3.5 per cent O_2 and 3.7 per cent CO. This represented an average run of 3¼ hours.

The extent to which the CO_2 could be raised without formation of CO depended upon the furnace design, the larger combustion chambers making possible the higher values of CO_2 without loss due to CO. With some of the settings tested, 15 per cent CO_2 could be maintained with but an occasional trace of CO.

When bagasse is burned at high rates of combustion (200 to 300 lb. per sq. ft. of grate surface per hour), the time required for complete combustion is lengthened so that extra large combustion chambers must be employed if a high CO_2 without CO is to be obtained. Owing to the large volatile content of this fuel, the completion of combustion occurs at a point much later in its travel than in the case of coal under equally favorable conditions. Consequently, with horizontal tubular boilers, the combustion in many cases under forced conditions will not be completed until the gases enter the tubes at the rear end. A consequence of this is a comparatively high temperature of gases in the combustion chamber, thus rendering a large tube surface of especial value for absorbing as much as possible of the remaining heat.

The rapid filling up of combustion chambers by deposits of ash which fuse to hard clinker forms an added reason for providing very large combustion spaces in the design of furnace and setting. In the case of vertical-pass water-tube boilers, the boiler should be set sufficiently high and with such arrangement of arches and baffles as to complete the combustion before the gases enter the spaces between the tubes.

Following are a few brief notes relating to the available heating value of Cuban bagasse, weight of bagasse per boiler hp-hr., etc., selected by Mr. Myers from his report on the plant referred to:

FUEL VALUE OF BAGASSE AND BOILER HP. OBTAINABLE

Assume mill to grind 300,000 arrobas[1] of cane per day with 75 per cent extraction, giving 75,000 arrobas of bagasse per day. Then, bagasse per hour = 3120 arrobas = 78,000 lb. = 39 tons of 2000 lb.

Available heating value of bagasse calculated for this plant, B.t.u. per lb. as fired	3,800
B.t.u. per boiler hp-hr. (= 34½ × 970.4)	33,479
B.t.u. to generate 1 boiler hp-hr. at 60 per cent efficiency	55,798
Pounds of bagasse to generate 1 boiler hp-hr. = 55,798/3,800	14.7
Bagasse available per hour when grinding 300,000 arrobas of cane per day, lb.	78,000
Boiler hp. from bagasse when grinding 300,000 arrobas of cane per day = 78,000/14.7	5,310

[1] An arroba = 25 lb.

Boiler hp. from bagasse when grinding 250,000 arrobas of cane per day 4,430
Boiler hp. from bagasse when grinding 200,000 arrobas of cane per day 3,533

The heat value of the bagasse was computed in two ways, first by formula, and second by an assumption of dry heat value (which Mr. Myers confirmed by bomb-calorimeter tests) and calculating the heat-moisture loss. The results agree within 2 per cent. Both computations follow:

Method 1. Calculation from this mill's analysis of February 19, 1917, with B. & W. formula, assuming according to Noell Doerr that $G = S/10$. Formula:

$$\frac{8550F + 7119S + 6750G - 972W}{100} = \text{B.t.u. per lb.}$$

Percentage analysis from laboratory:

H_2O	47.05
Fiber	44.55
Sucrose	6.81
	98.41
Glucose (assumed $= S/10$)	0.68
Total	99.09

Other gums and substances not shown by analysis.

$$\frac{381{,}000 + 48{,}400 + 4500 - 45700}{100} = 3882 \text{ B.t.u. per lb.}$$

Method 2. Assume 8300 B.t.u. per dry lb. ("Steam," Babcock & Wilcox Co.) and 47 per cent moisture. Then, total heat $= 0.47 \times 8300 = 4399$ B.t.u. per lb. as fired.

With flue temperature = 512 deg. fahr. and temperature of bagasse = 82 deg. fahr., heat to evaporate moisture =

$$0.47\,[(212 - 82) + 970 + 0.48(512 - 212)] = 585 \text{ B.t.u.}$$

Total heat per lb. as fired	4399 B.t.u.
Heat to evaporate moisture	585 B.t.u.
Available heat per lb. as fired	3814 B.t.u.

This checks to within 2 per cent of the value obtained by Method 1.

Available heat per lb. of combustible =

$$\frac{3814}{100 - (0.47 + 0.01)} = 7340 \text{ B.t.u.}$$

(Ash assumed at 2 per cent.)

H. L. Hutson wrote that the author's paper starts a train of thought which it is interesting to follow, namely: "What will our descendants do when the supply of stored sunshine in the shape of coal and oil is exhausted and they have to grow their own fuel from year to year?"

Taking Mr. Freeland's figures and assuming for Louisiana an average crop of 20 tons of cane per acre, we find that this would yield five tons of bagasse, which would have a fuel value equal to about one ton of coal. By a little figuring it can be shown that we can grow this fuel at about eight times the cost of coal.

Our descendants will, no doubt, use their fuel more economically than we do and may, in many cases, get more than eight times as much useful work out of it. In fact, in China, the ratio is no doubt larger than this, as they will cook their food in an oven heated by a bundle of stems of cotton or other crop, and then sleep on top of the oven by night and use it as a seat by day.

In parts of the tropics, alcohol made from molasses is cheaper than gasoline, and the efficiency of this fuel used in an internal-combustion engine is several times better than that of a steam engine using ordinary fuel.

The Cooling of Water for Power-Plant Purposes, by C. C. Thomas

This paper presents the results of an extended experimental investigation into the conditions governing the cooling of the condensing water of power plants by means of spray ponds. This investigation involved determining the efficiency of the cooling process under varying conditions of pressure at the spray nozzles, the temperature of the water to be cooled, the power required to circulate the water, the height of sprays above the pond surface, the effect of wind velocity on the cooling range, etc., and the work resulted in a large collection of data, much of which is presented in the text.

As a result of his experiments the author developed a new form of spray head or nozzle which is so adjustable that the film of water discharged may be broken into either a uniformly fine spray, or mist, or a large number of small drops, as desired. This method of spraying is particularly applicable to low-pressure work, a pressure of 10 in. of mercury giving an exceedingly fine spray, and 8 in. usually sufficing.

Probably the most completely controlled means for cooling water in large quantities is found in the forced-draft cooling tower. The newly developed spray head, however, provides for control of the system in a manner which, while somewhat less complete than in the case of the cooling tower, yields results comparing very favorably with those for the tower, and can be installed and operated at a much lower cost.

B. R. T. Collins, referring to efficiencies with water falling on the bare cement bottom of pond as compared with those when the pond contains its normal amount of water, wrote that the author's curves show 10 to 15 per cent higher efficiency with a full pond, thus controverting his statement in regard to the advisability of constructing a pond with practically no water in it. He believed the result shown by the curves indicates that a bare pond absorbs heat from the surroundings more readily and conducts this heat to the water sprayed upon it, thus raising the temperature of the water and reducing the efficiency. Hence, a certain depth of water should be carried in the pond to prevent this, 2 or 3 ft. being the best depth when everything is taken into consideration.

The author stated that the loss from cooling ponds with non-adjustable nozzles, in windy weather, is as high as 10 or 15 per cent. His experience is summed up by a typical case of a test made on a pond with non-adjustable nozzles at Hutchinson, West Virginia. An accurate record of all make-up water delivered to the pond during the month of August was kept, and this showed a total loss due to evaporation, drift and leakage, of 1.33 per cent of the water sprayed. The capacity of this pond was 3000 gal. per min.

There is one disadvantage in using adjustable nozzles such as the author describes when installed over a natural pond. The water in these ponds generally contains a certain amount of vegetable growth. This tends to clog the spiral slot, resulting in reducing the capacity of the nozzle appreciably, and increasing the size of the drops to a very considerable extent. This occurs in the course of a short period of time, about 10 to 15 min. after starting with a clean nozzle. This, of course, is an inherent difficulty with all nozzles of this type. It is fair to assume that an artificial pond or basin would become foul in the course of time, and cause the same difficulty.

The results reported in the paper bear out his experience in that the highest efficiency of a spray-cooling system is obtained in hot, humid weather, and the lowest efficiency in cool, dry weather. This is an advantage which a spray system has over cooling towers, as his experience has shown that hot, humid weather reduces the efficiency of towers to a very considerable extent. This, he believed, is due to the fact that the air is in contact with the water a much shorter length of time with a spray system than it is with a cooling tower of standard manufacture.

Edwin Burhorn contributed the following written discussion of the paper, the title of which he thought somewhat misleading, as it was entirely too broad, the subject-matter being devoted to cooling water by means of spray nozzles, particularly to a form of spray nozzle devised by the author:

Spray nozzles are used for cooling water for power-plant purposes but can also be used for cooling water for any purpose. Furthermore, there are many other methods of cooling water than those mentioned by the author and these different methods should have been covered by the author in order to fully justify the selection of the broad title of the paper.

The paper is interesting as far as it goes, but is not conclusive and leaves much to be desired. It is in line, however, with most of the papers that have been submitted from time to time covering various methods of cooling water, these limiting themselves to a particular apparatus. Attempts have been made to devise some general formula that could be used in connection with cooling towers, but on account of the many variables in connection with such work, the subject was given up. The process of cooling water is of such consequence and so vitally affects the efficiency of many operations that it is highly desirable that some reliable investigation be made regarding the relative value of the different methods available.

Among these methods are the plain cooling pond, spray nozzles alone or in connection with cooling ponds, cooling towers operated by means of air forced in by fans, or cooling towers in which the air is exhausted, cooling towers operating under the action of natural draft created by a stack, and cooling towers of the so-called "atmospheric" type, which operate through the action of natural air currents.

It should be borne in mind that all cooling systems are dependent on atmospheric conditions and vary with varying atmospheric conditions, and the maximum point of cooling is that of the temperature of the wet-bulb thermometer and not the temperature of the dewpoint. If the cooling system were so designed, with proper cooling surface, etc., it could reach the temperature of the wet bulb under all atmospheric conditions. From a practical standpoint, however, it is not advisable to so design such apparatus, as the great cost would not be justified by the additional reduction in temperature.

A comparison of the various cooling systems should include not only the cooling apparatus itself but also the auxiliary apparatus such as pumps for pumping the water and fans, if any, for creating an artificial circulation of air. In other words, the cost of operating various systems per annum should be investigated so that reliable data could be obtained. The interest on the investment and depreciation should also be taken into consideration and an investigation of this character would undoubtedly be of exceedingly great value. It would involve, however, considerable labor and expense.

Referring to the paper,[1] it will be noted that the curves in Figs. 7 and 8, showing the variation of efficiency of the adjustable spray head, were obtained by adjusting the spray head to suit the weather conditions existing at the time. It would be interesting to know how such adjustment is made and on what basis, as the weather conditions change from day to day and very abruptly even in a single day. It seems somewhat impractical to adjust these nozzles to suit all weather conditions. In a large installation, also, it would seem impossible to make this adjustment without shutting down the water supply or constructing a series of tunnels underneath the collecting basin to give accessibility to the adjusting rods. It is also somewhat difficult to tell whether the nozzle is adjusted for the most efficient conditions without carrying on a continuous series of tests unless the object were to attain a temperature of the wet-bulb thermometer, and of course in that case the nozzle would be adjusted until that temperature was obtained. The results of tests, however, seem to indicate that the reduction of temperature is, under most conditions, over 10 deg. above the temperature of the wet-bulb thermometer.

The curves in Fig. 10 are intended to show the wide variation of efficiency when proper adjustment of spray head is neglected. It is therefore of considerable interest to know how the spray heads can be kept properly adjusted to suit the ever-changing atmospheric conditions. The black circles refer to non-adjustable nozzles and the other circles to adjustable nozzles operating "without any attempt to obtain high efficiency." There does not seem to be much choice between the two types of nozzles and it would have been interesting to have seen the results for a period of one year where the adjustable nozzles had been operated with an attempt to obtain high efficiency.

In reference to Fig. 12, in which the efficiency is lower with a bare pond than with a full pond, Professor Thomas seems to be surprised at the results. This should not be at all surprising, as it is what would naturally be expected. The full pond offers considerable evaporating surface in addition to the surface exposed by the spray, and, furthermore, the evaporating surface is near the ground level where it can take advantage of prevailing air currents. On the other hand, the bare pond most likely did not offer the same amount of cooling surface as the full pond, and, furthermore, what cooling surface there was, was quite some distance below the ground level. This would therefore make it less accessible to air currents and naturally there would be less evaporation with the bare pond. The same reasoning may explain why the spraying on superposed inclined cement plates showed a falling off of efficiency owing to the fact that the cement plates may have offered obstruction to the prevailing wind currents and also reduced the cooling surface by collecting the spray into larger drops. No details showing the inclined cement plates were given and therefore a definite conclusion on this point cannot be reached.

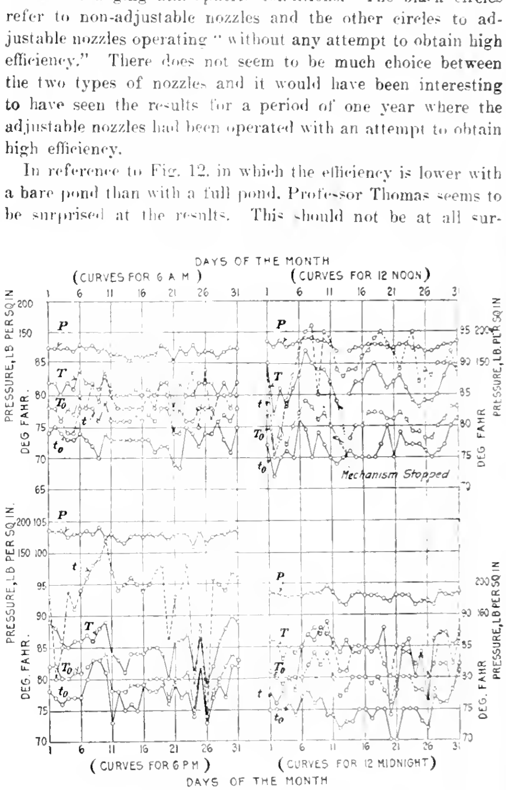

FIG. 1 CURVES SHOWING HIGH EFFICIENCIES WITH ATMOSPHERIC TOWERS

The effect of wind velocity on cooling range is indicated in Fig. 14, but not very much is said on this subject. This,

[1] The figure numbers given here are those in the complete paper as published in pamphlet form.

however, is a very important matter in obtaining satisfactory results. As the cooling of the water is done partly by convection and partly by evaporation, it is absolutely necessary in order that this process may continue that the air be in motion. Where the humidity is 100 per cent, all cooling is practically by convection, and the amount of cooling is limited entirely by the amount of air that passes over the water to be cooled. It can be readily seen, therefore, that under certain conditions a higher wind velocity will give very much better results. It is seldom, however, that the air is absolutely quiescent, there being at all times some wind movement; but even where there is no wind movement, the action of the heated water on the air would tend to create upward air currents and thus facilitate the action of the cooling. Were this not so, there would be absolutely no cooling possible unless there were wind movement. The efficiency of the cooling apparatus is based not alone on the range of cooling but also on the loss of water from all causes. Professor Thomas reports on the loss "due to evaporation." There is, however, an additional loss due to windage and this must be carefully known, as the total loss is what must be made up, and, if purchased, will represent an item of expense that should be taken into consideration. The loss from windage will depend on the velocity of the wind and also the size of the pond, and the size of the pond should be dependent on the maximum pressure of discharge at the nozzle.

The Johns Hopkins pond has an area of 962 sq. ft. and the amount of water handled varied from 20 gal. to 300 gal. per min., as indicated in Fig. 8. In the first case the area was about 48 sq. ft. per gal. per min., whereas in the second case the area was about 3.2 sq. ft. per gal. The loss of water due to windage would of course vary considerably, particularly with the average wind, but apparently no data are given on this important subject.

The loss due to evaporation would depend on atmospheric conditions and where all the cooling is done by evaporation the loss would be about 1 per cent every 10 deg. the water is cooled. It should be noted that Professor Thomas states the loss from non-adjustable nozzles in windy weather is as high as 10 to 15 per cent, but he does not show how with an adjustable nozzle the loss can be reduced by merely adjusting the nozzle. The windage loss might be greater with an adjusting nozzle owing to the fine spray, whereas the loss due to evaporation should be the same regardless of the nozzle, provided the cooling results are the same.

There seems to be some mistake in regard to the loss due to evaporation at the pond at Sparrows Point, Md., given by Professor Thomas as 0.31 per cent. At this pond, apparently, the water was reduced in temperature from 178 deg. fahr. to 125 deg. fahr., or a reduction of 53 deg. Unless the test was made in winter where there was no evaporation, or very little, then undoubtedly the loss should have been much higher: and particularly in the summer where the air temperature is high, the greater part of the cooling will be done by evaporation and in this case, if all the cooling were done by evaporation, the loss would have been, theoretically, 5.3 per cent.

Professor Thomas also endeavors to prove the advantage of the adjustable spray nozzle over the ordinary type of spray nozzle and states that the adjustable nozzle permits "regulation of the spray to suit weather conditions and to minimize loss of water and inconvenience to the nearby buildings due to driftage in windy weather." This is an admission of the inefficiency of the spray nozzle in general and a claim for an improvement due to the adjustable type of nozzle, but no proof is offered to justify the conclusion.

The curves in Fig. 8 show a variation of efficiency of the adjustable spray head with variation of capacity, but a close examination of the three curves shows them to be very nearly identical, the variation being only slight and hardly any advantage on this account.

Professor Thomas also states that "it has been somewhat surprising to find that very good cooling effect frequently obtains in very humid and even in rainy weather." He does not refer to any particular tests that have caused the surprise, but bearing in mind that it is possible to cool the water to the temperature of the wet-bulb thermometer, nothing would be surprising unless the temperature were reduced below that of the wet-bulb thermometer.

The results of cooling with spray nozzles were also compared with a few selected tests of one type of cooling tower, but as this cooling tower was not necessarily the most efficient obtainable, the comparison is not a fair one. The details of construction of the cooling towers were not given and the amount of water circulated in the cooling tower at the time the tests were made may not have been the full capacity of the tower. The data given were not sufficient to make these tests of any value for comparison. If, however, the cooling towers were all operated under their figured capacity, they show a variation *in efficiency* that seems to indicate improper design in some cases.

In Table 2, test No. 4 shows an efficiency of 0.928, whereas test No. 5 shows an efficiency of 0.391. If Professor Thomas would compare the results of his spray nozzles with the results that have been obtained with atmospheric-type cooling towers, in which the water has been reduced to within 1 to 5 deg. of the temperature of the wet-bulb thermometer, varying with the atmospheric conditions, he would then find that his results do not compare very favorably with those of that type of cooling tower.

Attention is also called to Table 8, showing tests of nozzles with spiral cores, and it is noted that on the test of nozzles consisting of two 1-in. sprays, high efficiencies are shown, namely, 0.798 in one case and 0.883 in the other. Table 7, of tests of the Thomas spray head with and without screen, does not show any test where the efficiency equals these, the highest shown being 0.75, in test No. 106, using the Thomas head with wire screen.

The spray-nozzle system undoubtedly has a field of usefulness but it is not adapted for cooling water where high efficiency is necessary or advantageous, such as in refrigerating and ice-making apparatus and steam turbines. In these plants the lower the temperature of the water used for cooling, the higher the efficiency of the apparatus, and cooling towers of the atmospheric type are able to cool the water to within 5 deg. of the temperature of the wet-bulb thermometer, whereas with the spray nozzles it is shown to be practically impossible to reach closer than 10 to 15 deg. of the wet-bulb temperature. In certain uses where high efficiency is not necessary, or for temporary service only, the spray nozzle is well adapted.

In order to show the high efficiencies actually obtained in practice with towers of the atmospheric type, the chart shown in Fig. 1 is submitted. This chart shows by curves the daily temperatures, during the month of July, the readings being taken each day of the month at 6 p.m., noon, 6 a.m. and midnight. These tests were taken from a tower in regular operation at Dallas, Texas.

Attention is called to the generally close shape of the curves of the temperature (T_o) of the water leaving the tower and the temperature (t_o) of the wet-bulb thermometer, and

particularly it should be noted that in several cases the temperatures were identical and the maximum variation about 5 deg. The wind velocity of course varied, and it should be noted that very little advantage could have been obtained in any of these tests had the wind velocity been higher than it really was.

This fact proves merely that the tower was properly designed and of sufficient surface in order to cool the water within 5 deg. of the wet-bulb thermometer under practically the worst possible atmospheric conditions. Furthermore, under the best atmospheric conditions the water was reduced to the temperature of the wet-bulb thermometer.

A. G. Christie, who presented the paper in the absence of the author, said in reply to Mr. Collins that they had found the bare pond not so efficient as the pond with a considerable amount of water. On the other hand, a full pond was not desirable in the North. There was a mean in the depth of pond which gave general efficiency—in their own particular pond about 18 to 20 in. instead of 3 ft.

The Steam Motor in the Automotive Field, by E. T. Adams

In this paper the author stated that the tremendous increase in the demand for automotive power has outdistanced the ability of the gasoline engine to meet this demand, chiefly on account of the condition that the supply of fuel is not now equal to the requirements.

The steam unit has many advantages for automotive service. Its high torque at low speed, its overload capacity, its smooth, flexible speed and power control have remained the standards of excellence, reached for but never attained by any gasoline motor.

The design of the steam unit is simple and many features of construction have been introduced which tend toward long life and low cost of upkeep.

Numbers of new steam trucks, tractors and pleasure cars are in service, or in process of manufacture or design. This effect and this demand will have a profound influence on the automotive industry.

John Younger, in a written discussion, entered a defense of the gasoline-propelled vehicle. He wrote that there has been a marked trend in design to improve carburetors to a point where kerosene can be used, and this, of course, to a certain extent, if successful, will practically double the quantity of gasoline available. There are today many internal-combustion engines running reasonably satisfactorily on kerosene, and the next year or two should see tremendous strides in the use of this or even slightly heavier fuels.

The author's statement that "the chief force which is bringing about the increased use of the steam motor is its superior fitness for automotive service, especially in the commercial field," is somewhat doubtful when the situation is studied at large. So far as he could see, there is no great demand, or any demand to speak of, for a steam automotive vehicle, for the simple reason that they were tried out as recently as ten years ago and practically abandoned. If you turn to the situation in England, where steam vehicles using coal, coke and gasoline have been used for some fifty years, you will find that the gasoline truck and the kerosene truck have supplanted the steam vehicle almost entirely. The same condition is found in the agricultural-tractor industry at the present moment, where the steam vehicle, which has so long been used by the farmer, is being actually forced out by the internal-combustion engine.

The upkeep of the gasoline truck, even with inexpert service, is not a serious handicap to the business. The cost of repairs on the gasoline motor truck is surprisingly low. Repairs lower than two cents per mile are very commonly met with.

The seeming simplification of the steam vehicle is so purely on the chassis. The engine, as Mr. Adams stated, is very similar to the gasoline engine. The rear axle, the front axle, the frames, the springs, the driver's seat, the radiator, or rather the condenser, are all duplicated in the gasoline-driven truck. This leaves practically the transmission and clutch, and this mechanical device, which usually gives absolutely no trouble, is replaced by a high-pressure steam boiler with its elaborate piping and connections and firing; so far this has not been worked out satisfactorily.

Before becoming too enthusiastic on the advantages of the steam motor in the automotive field, the whole history of the subject should be studied without any bias, and present-day installations of trucks of all kinds, not only in this country, but abroad, should also be studied very closely, and the repairs, etc., analyzed.

The author takes the very broad standpoint that whether steam will actually supplant gasoline or not is of minor import. It is quite possible that there can be a field for the two types, side by side, and anything that will help conserve our fuel supply must be worth while.

Wm. Clinton Brown[1] contributed a written discussion upholding the use of steam tractors. He said it was possible to produce a steam tractor having a total weight, including fuel, water and operator, around 125 lb. per b.hp. This is a machine lighter and far more compact than the majority of gasoline tractors. It is even only about one-quarter of the weight and less than half the size of the standard type of steam tractor of the same power.

John Sturgess presented a written discussion, which merits publication in full later, endorsing in general the author's conclusions, which he considered self-evident, but criticizing some of his references to details of construction.

He wrote that although the author referred to the extreme simplicity of the connection between motor and axle, the simplicity of the entire power plant merited equal emphasis. The modern automobile type of steam engine has but fifteen moving parts, compared to some hundreds in the internal explosive engine and its transmission.

The author stated that modern steam cars are of the multicylinder type. He had no knowledge of any steam car using or proposing more than two cylinders, for nothing would be gained thereby.

The author further stated that the uniflow type of engine is largely used, giving as the reason its simplicity and economy when operated non-condensing. He knew of only one advocate of the uniflow engine for automobile use, and he did not believe any claim was made by that advocate that cars have really been placed in the market as yet. In practice this design does not prove any simpler than, if as simple as, the contraflow, while in its application to automobile needs grave difficulties are encountered which do not occur in stationary practice.

He could not agree with the author's summary of boiler practice. As yet the water-tube type has not proven its commercial success, never yet having been marketed. The flash type is practically abandoned, owing to its several difficulties, including those of temperature and pressure control. On the other hand there are some thousands of cylindrical fire-tube boilers in daily use under every kind of service, in many cases

[1] Syracuse, N. Y.

the boilers being eight to ten years old. Among these, to his knowledge, there has not been one single case of destructive explosion due to construction methods.

He contested the author's statement that in spite of its high economy and honorable record in service, the system of converting oil under pressure into a vapor, and burning with a Bunsen type of burner, with pilot light for starting, is steadily being displaced by more modern design. His statement implies that there is a different practice already in vogue, which he doubted. Recent proposals have been made, but these could hardly be dignified by the title "modern designs."

Summarizing our present-day knowledge, as a basis for continued development, the author alluded to the clear-cut demands of the public growing from extended past experience with both steam and gasoline. Notwithstanding the efforts made, almost single-handed, against a deluge of fashion, to popularize the steam car, the writer thought the public generally is as yet uninformed as to steam-car performance.

J. D. Nies[1] and Allen C. Staley also contributed somewhat extensive written discussions in full agreement with the main argument of the paper, and emphasizing the leading features which the author brought out but differing with him in details.

Mr. Staley's discussion took up particularly the type of boiler of the steam automobile, and gave the arguments for and against the fire-tube and water-tube types respectively.

Mr. Nies considered one by one the desirable features of an automobile power plant, as enumerated in the advertisements of gasoline cars. These features are smoothness, flexibility, great reserve power, hill-climbing ability, acceleration, absence of gear shifting and low cost of operation. He then demonstrated how the steam motor compared with the gasoline motor in all these features.

[1] Lewis Institute, Chicago.

Edwin N. Trump emphasized the advantages of using a uniflow engine in the steam automobile. This engine gave a very flat economy curve, but the very high initial pressure gave such a high initial torque, at least double the ordinary running torque, that it was possible to start a uniflow-engine steam truck under conditions under which it would be impossible to start a gasoline truck.

Many people are interested in the steam truck because they feel that it will give them an ability to start a load and keep the truck going under conditions absolutely impossible with the gasoline engine.

The author, in closing, thanked the discussers for the courtesy of their retorts.

He said that it was really a romance of engineering that this development had, perhaps, first taken place in the field of the pleasure car, whereas sound business sense and engineering ability indicated that it is in the field of trucking and similar work that the steam unit has its best place.

He felt we were now at the start of what would become a tremendous industry, vital to the best interests of the country and of very great importance in the field of farming and trucking.

He had not desired to raise questions as to whether this design or that design were better, but merely to call attention to a new engineering problem which is before us in its infancy and which must be shaped and formed according to what is best for the country as a whole.

DISCUSSIONS OF PAPERS ON VARIED SUBJECTS

Opinions Expressed at the First General Session of the Annual Meeting, when Papers on Heat Transfer, Surface Resistance, Air Purification, Balancing, etc., Were Presented and Discussed

THE first General Session was called to order at 2:30 p. m. by Prof. Charles R. Richards, who acted as chairman. Six papers were presented at this session—the last two by title—as follows:

The Transfer of Heat Between a Flowing Gas and a Containing Flue, Lawford H. Fry.

A Study of Surface Resistance with Glass as the Transmission Medium, H. R. Hammond and C. W. Holmberg. Awarded Student Prize, 1917.

Apparatus for Cooling, Drying and Purifying Air, W. J. Baldwin.

Recent Developments in Balancing Apparatus, N. W. Akimoff.

Plotting Blower-Test Curves, A. H. Anderson.

Cross-Current Predeterminations from Crank-Effort Diagrams, Louis Illmer.

Mr. Fry Discusses Heat Transfer

The first paper to be presented was one by Lawford H. Fry, in which he developed a logarithmic formula covering the important thermodynamic process of the transfer of heat between a flowing gas and the wall of the containing flue, which formula, within the range of experimental data available, has been found to give satisfactory results.

E. A. Fessenden submitted a written discussion, in which he said that Mr. Fry's paper is a distinct contribution to the study of the transmission of heat by convection. While much excellent experimental work has been done, apparently no one has heretofore succeeded in correlating and harmonizing the results of many investigators so satisfactorily as is done in this paper. Formulæ showing the relations between factors involved in heat transmission by convection have been proposed in so many different forms that it has been difficult to realize that any connection exists between them. Instead of using these formulæ, proposed by various experimenters, Mr. Fry has gone to the original data and demonstrated that all the results may be satisfactorily represented by a single equation. The data are thus no longer more or less chaotic, but consistent, not only for each separate series of experiments, but for all. That this is true for data gathered under a wide variety of conditions encourages the belief that the real solution of the problem is brought nearer.

The general formula, Eq. [1], proposed at the New Orleans meeting in 1916,[1] was based upon two series of experiments and confirmed by several other isolated sets of data. No attempt was made at that time to evaluate the constant M. A little later, a full account of these experiments was published,[2]

and an empirical equation was given which satisfied these particular tests, namely,

$$M = 0.195U^{[illegible]}$$

where U is the weight of gases per hour per tube multiplied by the hydraulic depth in inches. The experiments did not cover a sufficiently wide range of conditions to warrant proposing this as a general formula.

Fig. 1 shows several sets of experimental data plotted upon log M and log U as coördinates. Since $U = Wr$ and log U = log W + log r, this method of plotting differs from that used by Mr. Fry only in shifting points horizontally by an amount depending upon r. The amount of displacement is constant throughout any single series, so that the slope of the lines connecting the points is unchanged. The data plotted include all those used by Mr. Fry, and in addition the following:

curves to be drawn to represent them, but they do indicate that the author's Equation [2] for M in its present form does not apply universally. It should be emphasized, however, that these latter data are very much beyond the range of those investigated by the author of the paper. In the Heine boiler the gas passage through the prism occupied by the tubes is not of circular cross-section, but is the space left around 3½-in. tubes on 7-in. centers, staggered. The hydraulic mean depth of the gas passage is about 1.31 in., and for a single tube the perimeter is 10.996 in. In order to conform to the author's Equation [2], the points for tests on the Heine boiler should cluster around the line marked H-H. Instead, the actual points indicate values of M about $2\frac{1}{4}$ times as large as are given by the proposed equation. A similar discrepancy is indicated for the Nicolson experiments.

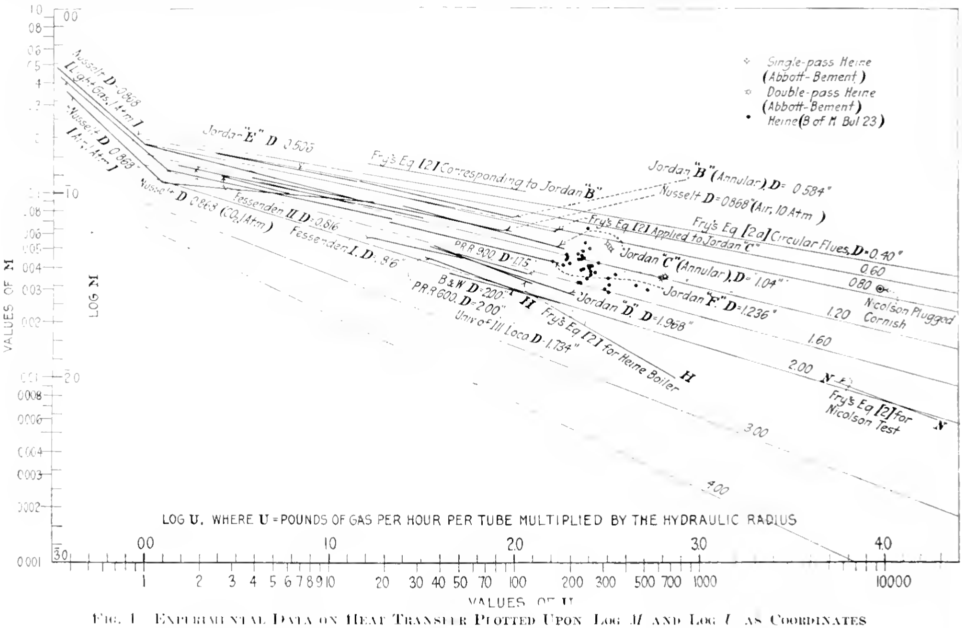

Fig. 1 Experimental Data on Heat Transfer Plotted Upon Log M and Log U as Coordinates

1 A series of tests made upon a consolidation locomotive.
2 Some tests made by the United States Bureau of Mines upon a Heine boiler.[4]
3 Some tests made upon single- and double-pass Heine boilers by Abbott and Bement.[5]
4 Nicolson's tests upon a Cornish boiler, in which a firebrick plug was inserted in the flue, leaving an annular gas passage 1½ in. wide.[6]

In order to reduce confusion, the separate experimental points for the tests used by Mr. Fry and for the additional locomotive series are not shown, but the heavy lines in the figure represent quite accurately the tests indicated. The light lines are plotted from the author's equation [2a] for flues of circular cross section. The other three groups of tests did not cover a sufficiently wide range of conditions to permit

A somewhat similar discrepancy may be shown for flues of circular cross-section larger than those covered by the experimental data. For example, in an ordinary return tubular boiler with 4-in. tubes, 16 ft. long, operating with 65 per cent overall efficiency and at rated load, with 18 lb. of air per pound of coal, an average of about 135 lb. of gases pass through each tube in an hour. The hydraulic depth is 0.933 in., and by the author's Equation [2] the value of M is 0.00912. If the water temperature is 366 deg. fahr. (corresponding to 150 lb. gage pressure) and the flue-gas temperature 600 deg. fahr., the temperature of the gases entering the tubes by Equation [1] is only 730 deg. fahr. Under the operating conditions assumed above, we might reasonably expect a furnace temperature of 2000 deg. fahr. to 2200 deg. fahr. The tempera-

[6] *Power*, Feb. 7, 1911, p. 222.

The boiler used in the Bureau of Mines tests had tiles completely encircling the lower row of tubes, forming a tile roof to the furnace. In computing M the furnace temperature was taken as the temperature at the entrance to the tube bank, and for the end of the tube bank the temperature was taken as that of the flue gases. Thus the assumed temperature drop through the tube bank is undoubtedly too high, with a corresponding error in M. This does not account for the large departure in the values of M from Mr. Fry's curve, since their allowances for the errors in the assumed temperature drop would reduce the values of M possibly 20 to 30 per cent.

ture drop from furnace to tube entrance would then be about 1300 deg. fahr. to 1500 deg. fahr., i.e., about 91 per cent of the total heat absorbed by the boiler is taken up by the shell by radiation from the firebox and by convection in the combustion chamber, leaving only about 9 per cent for absorption by the tubes. This is decidedly inconsistent with our usual ideas as to the value of the tube surface. If the temperature at entrance to the tubes is assumed to be, say, 1700 deg. fahr., the value of M is 0.0325. Rather curiously, considering its limited basis, the value of M for the same conditions computed from the formula $M = 0.195U^{-.43}$, mentioned above, is 0.0284. In the footnote on page 18 of the paper, it is stated that Eqs. [2] and [2a] are both applicable to flues of circular cross-section. They do not give exactly consistent results, however. For example, for the case of the return tubular boiler just considered, Eq. [2] gives $M = 0.00912$, while Eq. [2a] gives $M = 0.00812$.

Within the limits of the experimental data investigated, the author has apparently succeeded admirably in adapting the basic formula to widely varying conditions. Beyond these limits, i.e., for tubes larger than 2 in. in diameter and for passages of irregular cross-section, more experimental work is necessary before any very definite extension of the author's formula can be obtained. The Heine boiler tests and the Nicolson test, shown in Fig. 1, suggest that Mr. Fry's straight lines may be tangents to rather flat curves. Inspection of the author's Fig. 13 suggests that possibly the values of B and m, instead of being represented by straight lines, may lie on curves of parabolic form. This would increase B and decrease m for passages of larger "effective diameter" and thus increase M.

E. R. Hedrick wrote that there were reasonable grounds for supposing that there is really a break in the behavior when W had what was called by the author the critical value of (about) 5 lb. per hour. Also it was possible that a different relation for the effect of the flue diameter will have to be worked out when experiments were available in which a greater variety of values of d occurred. Possibly the relations suggested by Fessenden and Haney (Univ. of Mo. Bulletin, vol. 17, no. 26) might be found at least helpful in settling this question.

The author referred early in the paper to the fact that "no attempt is made to measure the rate of heat transfer." However, it should be emphasized that any formula that gave the temperature (or the heat-content) of the gas in terms of the distance along the tube, implied directly a law for the rate of heat transfer. This was the reason that the Osborne-Reynolds hypothesis led to a definite law for the drop in temperature along the tube, which enabled us to compare it directly with such experiments as those of this paper. It was shown in the paper by Professor Fessenden and himself (Trans. A.S.M.E., vol. 38, p. 407) that their formula [18], which is identical in meaning with formula [1] of Mr. Fry's paper, led directly to the formulæ [24] and [25] of their paper:

$$d\theta/dx = -m\theta \log_e(\theta / \theta_w)$$

or

$$d\theta/dx = -2.3026\, mR_0\theta_e^{-mx}$$

where the notation is that of their paper. From these, it was but a step to show that the rate of heat transfer (per degree difference in temperature per square foot of heating surface per second) was expressible by the formula

$$\frac{C_p w}{\pi d} \frac{1}{\theta - \theta_w} \frac{d\theta}{dx}$$

where w is the weight of gas passing per second, C_p the specific heat of the gas, and d the diameter of the tube. Hence, the rate of heat transfer was proportional to

$$\frac{C_p\theta}{\theta - \theta_w} \log \left(\frac{\theta}{\theta_w}\right)$$

In any event, the rate of heat transfer was certainly not proportional (simply) to the difference in temperature, as was abundantly shown by the experiments quoted in this paper.

J. F. Barkley[1] wrote that, after an extended experimental study along the lines of the subject of the paper, he felt that any equation which included all the physical factors involved in such a heat transfer would unquestionably be too complicated for practical purposes. It seemed to him that there would always be necessary a simple equation, such as that of Osborne-Reynolds, including, perhaps, a few of the main physical factors. These together with experimental constants would serve to obtain desired quantities within certain ranges.

The temperatures taken by the author from the B. & W. experiments were derived by calculation, using the specific heat of the gases. The specific heats of gases, particularly at temperatures from about 1500 deg. fahr. up, were not well agreed upon by the best authorities. This variation amounted to several hundred per cent at 2500 deg. fahr. What was needed was some experiments where a heat balance could be taken which would show the possible inaccuracy of the data, plus or minus.

As to the accuracy of the formula, he would like to ask what the maximum possible per cent error would be if one were to solve it for some quantity, say, the length of a tube.

Gottfrid L. Ostgren asked whether there were any published data on formulæ to be used for calculation of heat transfer for large flues, over 2 ft. in diameter, or circular or rectangular cross-section. Frequently an engineer had to design a furnace where he was using waste-heat gases to heat air in a closed space, for instance, in an annealing furnace, and the question of determining the proper radiating surface in order to obtain a certain temperature in the annealing furnace was rather important. He had occasion to construct an annealing furnace of that type not very long ago, and while he had struck the temperature very closely, he had found that when doors were opened on the two sides of the furnace and the temperature dropped, it took a rather long time to get the temperature back again. By putting conical deflectors inside the flue, where the waste gases were passing, it was possible to obtain more contact between the heat units and the steel flue, which improved the transfer quite considerably.

D. S. Jacobus said that the heat-transfer rate of conduction from the gases to the cooling surface was only one of the elements to be considered in designing a boiler. For example, the effect of radiant heat on the tubes nearest the furnace was an important element, and unless this was included in an analysis of efficiency the results would be considerably in error. When it came to the final analysis and securing the maximum efficiency from a boiler, the rate of heat transfer must be considered, and it was necessary to balance up a loss in draft against securing a higher boiler efficiency.

There were a number of elements that had to be taken into account in designing a boiler; for instance, the effect of radiant heat. It was necessary to expose enough of the heating surface of the boiler to the radiant heat to keep the temperature of the furnace within the limit that present-day brickwork will stand.

[1] Asst. Efficiency Engineer, Carnegie Steel Co. E. T. Works, Braddock, Pa. Formerly with United States Bureau of Mines.

Again, the entering velocities of the gases between the tubes should not be made too high. If the area for the flow of the gases was unduly constructed there might be trouble, especially at the higher ratings at which boilers are run today, when the tubes become fouled through the accumulation of soot, which would lead to an excessive draft resistance.

It was also necessary to provide a sufficient furnace volume and a proper length of travel for the burning gases in order to consume the products of combustion, and also to prevent a blowpipe action on the boiler tubes.

An interesting addition to this valuable paper would be an analysis combining the draft losses with the variation of heat transfer to determine the theoretical proportion of the areas between the tubes for the flow of the gases to give a maximum heat absorption for a minimum draft resistance. An answer to this problem has been found by experiment and practice for certain classes of boilers, but it would be interesting to have

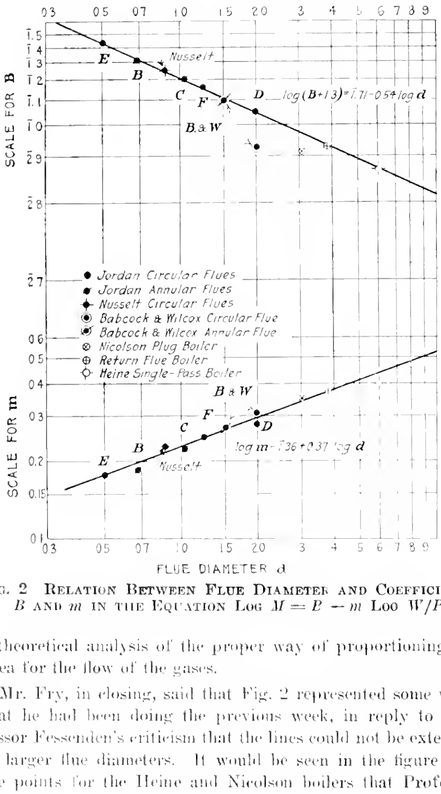

FIG. 2 RELATION BETWEEN FLUE DIAMETER AND COEFFICIENTS B AND m IN THE EQUATION LOG $M = B - m$ LOG W/P

a theoretical analysis of the proper way of proportioning the area for the flow of the gases.

Mr. Fry, in closing, said that Fig. 2 represented some work that he had been doing the previous week, in reply to Professor Fessenden's criticism that the lines could not be extended to larger flue diameters. It would be seen in the figure that the points for the Heine and Nicolson boilers that Professor Fessenden referred to, were well taken care of in both lines. If the Heine boiler tests of Professor Fessenden were replotted on the basis of weight of gas divided by perimeter, they would be found to show agreement with the author's lines plotted on the logarithmical basis.

He believed that a formula of this sort could be applied to the condition that Mr. Ostgren spoke of in air flowing through the inner flue, if it was possible to get the mean temperature of the flue wall.

In conclusion, he desired to point out that the paper referred to the point that was mentioned by Dr. Jacobus in regard to the loss of draft, viz., that by decreasing the flue diameter the rate of heat transfer could be increased, but that this would be done at the expense of loss of energy in forcing the gas through the flue. The loss of draft—loss of head—in passing through the flue was the price that must be paid for increased heat transfer, and if a formula similar to that used for loss of temperature could be obtained to take care of loss of head, it would be possible to figure out exactly what had to be paid for a given rate of heat transfer, and to calculate for any kind of a boiler with greater certainty.

He would add that two of the important series of tests mentioned in the paper were carried out by the Babcock & Wilcox Company, under the direction of Dr. Jacobus, who had courteously placed them at his disposition.

MR. HOLMBERG PRESENTS PAPER ON SURFACE RESISTANCE

The next paper to be brought before the session was one by Messrs. H. R. Hammond and C. W. Holmberg,[1] which had been awarded the Student Prize for the year 1917. In introducing Mr. Holmberg, who presented the paper, Chairman Richards feelingly referred to the sudden demise, during the previous week, of Mr. Hammond, who had hoped to present it in person. The paper describes an investigation of heat transmission through glass and gives a formula by which the combined coefficients of transmission, as well as the conduction values for the glass inside air surface and outside air surface, may be calculated.

Prof. A. J. Wood, in a written discussion, called attention to the fact that tables, for the most part, give conduction values only. To apply these to the usual practical problems it was necessary also to know the values for the surface effect. The table in the paper showed the effect of temperature range on heat transmission, and this was found to influence the results to a considerable degree.

On December 3 Prof. R. B. Fehr and he had discussed, before the American Society of Refrigerating Engineers, the results of recent work at the thermal testing plant of The Pennsylvania State College. Among other constants given, it was stated that under usual temperature conditions and for "still" air, the total surface transmission for *both sides* of glass, corkboard and building paper was found to average about 22 B.t.u. per 24 hr. per sq. ft. per degree difference, which value was approximately 0.9 B.t.u. per hr. per sq. ft. per degree difference. Pending the results of more extended tests, this value was believed to be a safe one for general practice.

L. B. McMillan submitted a written discussion in which he said that the conclusions which the authors had reached regarding the importance of the air-film effect were in accordance with the theory on the subject and checked closely with the results by other investigators. However, their work showed more forcibly than ever the need for full and complete data on the subject of surface resistances.

Considerable work had already been done on this subject—much more than would appear at first thought. For example, it had been nearly one hundred years since Péclet made his classical experiments, determining radiation coefficients for a number of materials, and these, in connection with convection coefficients, indicated the rate of flow from the surface or conversely the surface resistance. One reason why there seemed to be such a scarcity of data on surface resistances was that this relationship of surface resistance to surface transmission was very generally overlooked.

Dulong had built on the work of Péclet and worked out equations for the radiation coefficients at various temperatures.

[1] 354 Senator St., Brooklyn, N. Y.

These were given in Kent's Pocket-Book, together with tables prepared by Box which facilitated the finding of the coefficient at any temperature. This would go a long way toward filling the need except for the fact that Péclet's coefficients had been found to be very considerably too low. For example, Paulding (Stevens Indicator, vol. 19, p. 393) has shown that Péclet's coefficient of 0.64 for iron was much too low, and that modern tests proved that this coefficient should be about 0.87.

Péclet's results were therefore of interest mainly for their historical importance, and because of the thoroughness with which he had attacked the problem, even at that early date.

Fig. 3 showed results of some of the modern investigations[1] as compared with Péclet's results, and illustrated how well the modern tests agreed, even though made by widely different methods. For example, the tests by Barrus, Brill, Jacobus, Eberle and that labeled "Stevens Indicator" were condensation tests, while those by the writer were by the electrical method, and yet the results were in very close agreement, while the curve showing Péclet's results fell far lower.

The data referred to were not presented as being directly comparable with the results presented by the authors of the paper under discussion, as these did not refer to glass surfaces. However, the data were of similar nature, as the results shown in the figure represented surface conduction for cylindrical surfaces where the character of surface was that of an ordinary steel pipe.

In pointing out the difference between Péclet's results and those of modern tests this was not intended as a criticism of Péclet's work, for considering the time at which it was done it was a great achievement, but now, with infinitely better facilities for research, we should repeat his work on even a larger scale than that which he attempted, and in addition to having the coefficients for various surfaces and laws showing how they vary with temperature, we should have also the laws showing the effect of wind velocity, humidity, etc.

This, however, would be a very large undertaking and could not be handled by one individual or concern, though some of the larger manufacturers of insulating materials had well-equipped laboratories and would be glad to coöperate in such a movement. The Bureau of Standards had done much creditable work along this line, and would probably do more, but great results could be accomplished in the university laboratories and experiment stations as had been shown by the paper under discussion.

The foregoing might appear at first thought to be rather much of an academic discussion, but it decidedly was not, and a few illustrations would show how useful these coefficients were in the solution of everyday engineering problems.

For example, a great deal of data regarding conductivities of materials was now available, and with complete information as to surface resistances the calculation of heat-flow problems would be much less of a bugbear than it had been in the past.

Furthermore, the only effect which wind velocity could have upon the heat losses from a surface was to decrease the surface resistance, therefore this effect could easily be isolated and determined. The same was true of air humidity, except where the material was affected by moisture.

As pointed out by the authors, the surface resistance was the greater part of the resistance to heat flow through good conductors of heat, and for accurate solution of problems of this kind accurate data on surface resistances must be had.

Furthermore, it was often desirable to estimate beforehand the temperature of the surface of a stack or furnace when the thickness and character of the walls and the temperature of the inside of the furnace were known.

As an illustration of the use of surface resistances in the solution of an actual problem, a 4-in. brick wall might be considered, the conductivity of the brick being taken as 6 and surface conduction as 2. This would make the rate of heat flow $= 1/[1/2 + 4/6 + 1/2] = 1/1.67 = 0.6$ B.t.u. per sq. ft. per deg. temp. dif. per hour. It was to be noted that the combined resistances of the two surfaces were greater than the resistance of the four inches of brick.

If in place of the brick the wall had been 4 in. of a good insulating material having a conductivity of 0.5, the rate of heat flow would then have been equal to $1/[1/2 + 4/0.5 + 1/2] = 1/9 = 0.11$ B.t.u. per sq. ft. per deg. temp. dif. per hour. In this case the resistance of the material was 8 times the combined resistances of the two surfaces.

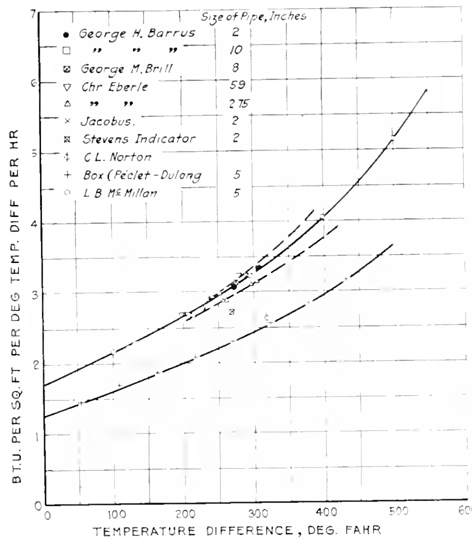

FIG. 3 COMPARISON OF RESULTS OF VARIOUS INVESTIGATORS ON HEAT TRANSMISSION FROM BARE PIPE SURFACES TO AIR

Therefore, while these things could be done with a considerable degree of accuracy, even with the data now at hand, it would be quite an advance to have full and complete information. This was particularly true regarding the good conductors of heat, for the data now available served very well in insulation problems where air resistance was the small part of the total resistance.

Returning again to the paper under discussion: The authors stated under Conclusions that the greater resistance was at the outside surface of the glass, and attention was called to the fact that this referred to the conditions of test and was not made as a general statement, as the resistance of the inside surface during these tests was greatly dissipated by the air circulation.

Also, it would seem from former investigations that the curves in Fig. 6 of the paper should bend upward at the higher temperatures instead of downward. However, a wider temperature range might be necessary to make this change con-

[1] Geo. M. Brill, Trans. A.S.M.E. vol. 16, p. 827. Geo. H. Barrus, Trans. A.S.M.E., vol. 23, p. 791. C. L. Norton, Trans. A.S.M.E., vol. 19, p. 729. Prof. D. S. Jacobus, Stevens Indicator, vol. xix, p. 12; Stevens Indicator, vol. xix, p. 388. Chr. Eberle, Verein Deutscher Ing., Mit. über Forschungsarbeiten, Heft 78. Thomas Box, Practical Treatise on Heat and Kent's Pocket-Book. L. B. McMillan, Trans. A.S.M.E., vol. 37, p. 921.

siderable, and for the given range the figures were probably very nearly correct.

In conclusion, he wished to repeat that he believed it would be well worth the trouble to investigate through a wide range of conditions the surface resistances of various materials.

Prof. E. A. Fessenden thought the temperature-gradient curves given in the paper were important, and it seemed to him that it might very well be emphasized in this connection that, where total transmission was being sought, the thermometers for measuring temperature should be placed at a considerable distance from the surface to get on to the horizontal part of the curves and away from the sloping gradient—possibly 10 inches or a foot or more away, but at least not near the surface.

Arthur K. Holmes called attention to the fact that in Fig. 5 the conduction of heat through glass seemed to vary between 18 and 22 B.t.u., while in another place it was stated that "the combined-coefficient values check up thoroughly well with the values 0.96 (dry glass) and 1.1 (wet glass) for a single window," or about one-twentieth as large.

L. B. McMillan said that in one case where the temperature went up to 500 deg. and the thermometers were placed at least 5 ft. away, unless they were shielded by a sheet of paper between them and the heated pipe, they would still, by radiation from the pipe, show a higher temperature than the room air. He therefore thought Professor Fessenden was quite right in saying that it was the temperature of the room air that should be taken as the lower temperature.

Mr. Holmberg, in closing, said that Mr. Holmes had mentioned that the conduction values given for glass seemed to be about 15 to 20 times those that were spoken of in regard to the combined-coefficient values as checking up fairly well with the values 0.96 and 1.1 for a single window. It was to be noticed, however, that in this connection it was said that, "Moreover, they [these values] show that the transmission varies linearly with the temperature differences." So, it would seem, they were speaking of transmission values. The transmission value took into account not only the conduction of the glass but the two surfaces, and it was the two surface values which so reduced the amount of heat that would go through there as to give that decreased value.

The glass itself was a very good conductor, and if taken by itself, without any surface resistance, there was very little resistance to heat going through; but with the two air resistances taken in conjunction with it, it gave the bottom curve on Fig. 5, marked "Transmission," which represents the value spoken of in the paragraph referred to by Mr. Holmes.

Lest misconception should arise regarding the conduction curves plotted in Fig. 5, he would say that the abscissæ represented total temperature differences (inside to outside of glass). As indicated in the table preceding the figure, the conduction curves were plotted merely for the purpose of comparison with the total-transmission curve. It was also to be noted that in formula [2] k should be replaced by $1/k$.

Mr. Baldwin Describes Apparatus for Purifying Air

The next paper, by W. J. Baldwin, described an apparatus for purifying air and regulating its temperature and humidity by mechanical means. In principle it consists of the use of a cold spray for the purification process, after which the excess moisture, together with particles of dust, excess CO_2, etc., are separated from the air by centrifugal action. In one of its original forms the device was applied to the porthole of a ship for the purpose of drawing into the cabin large quantities of air but excluding rain or spray. It has also been used to remove CO_2 from vitiated air, as in the compartments of a submarine, and for removing particles of dust from the gases of combustion in a chimney.

In lieu of reading the paper, Mr. Baldwin gave brief particulars of views which he had projected on the screen, showing various forms of the apparatus and uses to which it had been applied. The largest apparatus at present in use handled from 16,000 to 20,000 cu. ft. of air per minute. It was a dry apparatus and was used in the Flatbush Gas Company's plant on one of their boilers, and had been in use for over a year. It removed 96 per cent of the dust that would ordinarily escape up the chimney and 46 per cent of that dust was so fine that it would go through a sieve of two hundred mesh.

It was desirable, said Mr. Baldwin, not to use water when handling chimney gases. If water was used acids would be condensed, and the fuse would give out in a very short time, especially if salt water was employed. In New York and in Brooklyn where a salt-water spray running over an apron was used, it attacked the iron so rapidly that it disappeared in a few months.

In portland-cement mills the apparatus when operated dry would recover 83 per cent of the cement escaping from the top of the chimney, floating out over the country, and when water was turned on, 100 per cent.

The apparatus could also be used for throwing down and removing by-products from escaping gases from mechanical plants and gas-producing apparatus, etc.

Mr. Akimoff Describes His Latest Balancing Apparatus

In the paper by Mr. Akimoff were described new methods which he has recently developed and applied in a new type of machine for combination static and dynamic balancing. In operation a clamp is attached to the body to be balanced, whereby a known centrifugal force is introduced when the body is rotated, for the purpose of neutralizing the static or dynamic unbalance of the body. By suitably constraining the motion of the rotating body, either the static or dynamic unbalance, or the combination of both, may be accurately measured through the adjustment of the clamp.

Clarence P. Crissey, who opened the oral discussion, asked the author if any rotors had been balanced on his machine and then run at or through critical speed, and if so, did experience indicate that it would be commercial to design multi-stage apparatus having packings between stages, with a critical speed below but in close proximity to the operating speed? In other words, could apparatus be balanced so closely that the critical speed could be disregarded?

In reply Mr. Akimoff said that he thought it was a problem different from dynamic balance. It seemed to him that dynamic balance proper ended when a body was balanced in such a way that in a perfect vacuum, without any outside effort, it would run perfectly and without any oscillation whatsoever. Machines could be built commercially, without very much trouble, because it was just as easy to get a near balance as to get perfect balance by the means described, and, of course, vibrations would not be set up except by the action of some outside agency. Torsional vibrations were an entirely different proposition and were due to the distribution of mass on the line of the shaft. The torsional problem, which was very difficult to solve, was illustrated by a plain shaft with a flywheel on either end.

H. G. Reist asked whether there was any method of marking the shaft or indicating where the counterweight was to go.

In reply Mr. Akimoff said that the amount and location of the counterweight were fully indicated by the position of the clamp, which could be quickly adjusted after a few trials. There was a way of making the clamp so that the adjustments could be made without stopping the machine, but that would be the subject of a communication by him at some future time.

Mr. Reist said that with reference to the matter of getting a balance that would run at critical speed, he might say that this was practically done in a different type of balancing machine in which the rotating body was supported by a flexible cable, but the effect was practically similar.

W. J. Baldwin described a method which he had devised and successfully used for balancing fans and other machines having parts attached to a central hub. It consisted of two radial arms adjustable at any angle to each other on the shaft of the machine. If these arms when both opposite the "heavy" side of the machine did not hold the machine in running balance, they were made heavier. If they were found too heavy they were shortened. Minor adjustments were made by moving slightly one of the arms.

F. Van Buren Connell said that recent developments in the automobile and airplane industries had emphasized greatly the subject of balance, which already was known to be very important, and was now considered a distinct branch of mechanical engineering and not a shop method at all. Up to the present time the methods of obtaining balance had been very crude. One of the old standbys had been the parallel ways referred to, which were only good for static balance, and then only under conditions of light weight and small journal bearing. With large journal sizes and heavy weights the results showed such a discrepancy that they positively prohibited the use of parallel ways for obtaining even static balance. With Mr. Akimoff's machine results were obtained with a mathematical exactness that had never been obtained before, and there was no guesswork about it—it was not a hit-or-miss system. By systematic trial adjustments they obtained the exact amount of unbalance and the exact plane in which they should drill or add weights to give that balance.

The subject of balancing was an extremely important one and a very practical one, too, because the actual work of indicating could be done by a mechanic. There should be an efficient balancing engineer, however, a new species, to direct the mechanic's work, because the subject required something more than the trial methods and the horse sense that had been applied to it so far.

Mr. Illmer's paper, an extended abstract of which was published in the October Journal, was then presented by title. No discussion being forthcoming, the meeting was declared adjourned.

Professor Anderson on Plotting Blower-Test Curves

In his paper, which was presented by title, Professor Anderson described a new method of plotting blower-test curves, and demonstrated its utility by the solution of problems from graphically recorded test data.

Diagrams were given for impellers with blades tilted forward, blades radial, and tilted backward. Curves showed rates of discharge in cubic feet per second and volumes discharged per second per horsepower.

J. M. Spitzglass, in a written discussion, said that the curves given disclosed many interesting features in the characteristic properties of the various types of blowers, which could not be very well shown in the usual pressure-volume curve of the blower. It was interesting to note that in Fig. 1, representing the characteristic curve for blades tilted forward, the volume lines were uniformly converging toward the higher speed, so that some of them crossed each other, even within the limited region of the curve. This would indicate that at the higher speed of this special blower there was practically no variation in the pressure for any volume delivered by the blower, or rather the least variation in the pressure would change the volume from a maximum to a minimum, and vice versa, and it would be very inefficient to use a blower of that kind where a more or less constant volume of air was required.

In Fig. 2 the volume lines were less converging than in Fig. 1, while in Fig. 3, the characteristic curve for blades tilted backward, the volume lines were practically parallel to each other, which meant that in this kind of blower the volume of air delivered could be kept more or less uniform, even though the resistance to the flow should vary to a certain degree.

In this experimental case the discharge of the fan was varied by the use of different-sized orifices at the outlet of the fan. In the practical operation of blowers it was not so easy to control the resistance offered to the flow of the air. The air might be blown through a thick fuel bed, which might vary in height and also in resistance, and in such cases it was not the static pressure, nor even the mechanical efficiency, that interested operators as much as the number of cubic feet per horsepower that could be obtained from the blower, and curves plotted in this manner showing the amount of air that could be obtained for any condition were very valuable for that purpose, because they showed at a glance under what conditions it was possible to obtain the maximum quantity for a given amount of power used on the blower.

Regarding the mechanical efficiency shown for the given blowers, he wished to ask why the efficiency was so low, not being much over 40 per cent in any one of the given blowers, and why the blower with the blades tilted backward showed the lowest efficiency of all, when theoretically this kind of blade should show higher efficiency than the others.

F. R. Still wrote that while the author's curves were interesting, and perhaps might be valuable for some purposes, he thought the most useful curves for all purposes of fan or blower application were those of the kind employed by the American Blower Company, which were developed from characteristic curves plotted from test results. In his opinion, no other method covered the performance of a fan so completely, and at the same time cleared up what otherwise was so frequently very puzzling in results from fan installations, especially to those who did not have to deal with fans frequently enough to understand them thoroughly.

G. F. Gebhardt wrote that he had applied the authors' curves to comparative tests of a number of fans of various makes, and found that the commercial characteristics most desired were brought out in a much more satisfactory manner than with the customary method of plotting results. It was true that considerable time was required to plot the curves as indicated, but the ease with which the various problems involved might be calculated from the graph might greatly justify the initial expenditure of time. No claims were made in the paper as to the accuracy with which the investigation was conducted, but he had had the privilege of studying the test methods used and had been greatly impressed with the painstaking and exacting care with which all measurements were made and recorded. The paper, though brief, was a marked acquisition to the art of blower testing. He would like to ask the author

why the capacity curves between 0 and 35 cu. ft. per sec., Fig. 1, had been omitted.

C. M. Spalding wrote that the curves given in the paper brought out very clearly certain phases of blower action, and that it would be very desirable if the author would add some definite information about the dimensions of the fans, and would also tell whether the blades were plain or curved, etc.

In examining the data presented, he had been interested to see what other aspects of the matter would appear by taking the information furnished by the author and comparing it in other relations, more especially as regarded the relative performance of the three types of fans. He had constructed the tables which follow by taking two values as a common basis for all three types of fans and setting against them the variable values of the other items covered in these data. The variable items were stated both in the actual values taken from the curves and in the proportionate values by assuming some one of the three types of the fans as unity, or rather 100 per cent, and comparing the performance of the other two types of fans. It would be noted that these tables did not select the most favorable condition of operation of all three types of fans, as in order to make the comparison it was necessary to select as a common basis points which appeared on all three of Professor Anderson's curves, but even with this limitation they were very interesting.

TABLE 1 COMMON BASIS: PRESSURE AND R.P.M.

Basis		Performance						
			Total Output, Cu. ft per sec.			Efficiency, Cu. ft. per sec. per hp.		
Press., inches water	R.p.m.	Values	Blades tilted forward	Blades radial	Blades tilted backward	Blades tilted forward	Blades radial	Blades tilted backward
1.50	1400	Actual	73 0	57.0	32.5	15 00	17.95	20.05

The author in closing said that Professor Gebhardt brought up the point of why the curves between 0 and 30 cu. ft. per sec. had been omitted in Fig. 1. This was due to the fact that for less than 30 cu. ft. per sec. the curves overlapped and would have been indistinguishable in the small scale to which the figures were drawn for the cuts. Curves drawn to a larger scale than shown in the figures illustrated the performance of the blowers very clearly.

He had not yet had the privilege of reading Mr. Still's remarks, but had no doubt that the information he had to offer would be instructive.

Mr. Spitzglass' application of the curves to forced-draft practice was important. Another application was that to ventilation systems where it was necessary to move air against the friction in the ducts. The correct speed for a certain friction head and volume might be readily selected, or if the friction head was diminished by shutting some of the air outlets the proper blower speed might be determined from the chart and the blower slowed down, resulting in economy of power.

FURTHER DISCUSSIONS OF VARIED PAPERS

Proceedings of the Second General Session at the Annual Meeting, with Authoritative Papers by F. W. Dean, L. C. Loewenstein, H. L. Gantt, C. J. Ramsburg and C. H. Bedell

At the second General Session of the Annual Meeting, at which Vice-President Arthur M. Greene, Jr., presided, the following seven papers were presented, the first, by F. W. Dean, and the last four—contributed by Local Sections—being read by title:

An Account of the Engineering Work of E. D. Leavitt, F. W. Dean.

A Volume Regulator for Blast-Furnace Engines, L. C. Loewenstein.

Expenses and Costs, H. L. Gantt.

By-Product Coke and Coking Operations, C. J. Ramsburg and F. W. Sperr, Jr., contributed by the Philadelphia Section.

The Submarine, C. H. Bedell, contributed by the New York Section.

Combined Stresses, A. Lewis Jenkins, contributed by the Cincinnati Section.

The Trumble Refining Process, N. W. Thompson, contributed by the San Francisco Section.

Dr. Loewenstein Presents His Paper

The paper presented[1] by L. C. Loewenstein dealt at length with the problem of properly regulating the quantity of air supplied to blast furnaces and had for its main object the description of a new instrument, named a volume corrector, which, when used in connection with an impact-float constant-volume governor, will correct for any changes in the temperature, barometer and humidity, so that the air supplied to a blast furnace will, at all times, under any atmospheric conditions, deliver a perfectly definite and predetermined weight of oxygen to the blast furnace, and is so designed that it requires only one setting for each correction.

C. P. Crissey, in a written discussion, said that, in addition to the methods mentioned, it was also perfectly commercial and good practice to test turbo-blowers by means of a nozzle placed at the inlet, which made it unnecessary to disarrange the discharge piping or waste the air.

Referring to the author's remarks on the orifice method of measurement, he stated that he was unaware of any objection to attaching a parallel section at the end of the orifice. On the other hand, experience had not shown this to be necessary when the nozzle was properly shaped. The impression should not be gained that nozzles without the straight portion were inferior in accuracy or in any other respect.

The author had described a very ingenious device, but it was not automatic in its operation, and until something automatic was developed he believed that tables and charts would be more satisfactory for use in giving equivalent settings for the sliding weights on the scale beam of the air meter.

R. J. Wysor,[2] in a brief written discussion, said that the author assumed that a constant weight of air should be delivered to the furnace under all conditions, whereas, from an operating standpoint, it was frequently found advisable to change this weight for different furnace conditions, beyond that corresponding to varying atmospheric conditions. Again, the author took no cognizance of leakage after the blast had left the blower, that is, through the cold-blast main, stoves, hot-blast main and bustle pipe, with the numerous valves, seams and joints, offering opportunity for loss of air. This loss in different plants varied from probably a minimum of 5 per cent to a possible maximum of 25 per cent. And at each furnace it was a widely variant quantity due to changes in pressure and temperature of the blast, atmospheric conditions, state of repair of the system, etc. In other words, no matter how accurate the governing device might be, there was still considerable difficulty in delivering a fixed weight of oxygen to the furnace per unit time.

Linn Helander thought that a clearance space of 7 per cent was rather high, and that 3 per cent was more usual; also, that the variation in pressure of from 10 lb. to 30 lb. seemed a very large increase in pressure for a single blowing engine.

Again, as to the clearance in which the expansion of the air occurs, at the end of the stroke the pressure was up, and it was full of high-pressure air. Assuming that the pressure went down to atmospheric at a point further on, it would be necessary to subtract the clearance volume from the corrected volume, which would be 7 per cent from the 11.8 per cent mentioned in Par. 7, or 4.8 per cent.

Dr. Loewenstein, replying to Mr. Crissey, said that a nozzle without a straight portion could be used, but in that case there was no way of telling whether the jet as it left the nozzle covered the entire area.

In regard to using tables or charts for setting the sliding weights, he would say that there were three variables, and an infinite number of combinations. As to the barometer, this could be set to each 0.1 in. of variation in the instrument. Similarly, there were an infinite number of variations of temperature and humidity, and any one who had attempted to get up a set of tables or a set of curves would realize how difficult it was and how voluminous it would be, and secondly, how much easier it would be to use the instrument by the three settings, and automatically get the reading, than to go over a set of tables and probably make a mistake. Also, the superintendent in walking through a blast-furnace plant could easily check up the three settings by the operators and see that the barometer, temperature and humidity were exactly corresponding to the instruments hanging close to the main instrument. He could not do that as readily if he had a set of tables to check.

In reply to Mr. Helander he would say that the statement as made in the paper was absolutely correct in reference to volumetric displacement, because the clearance space between the cylinder head and the piston was not the entire space. It included all the spaces down to the valves, and it was positively known that the volumetric efficiency of blowing engines was seldom above 85 per cent in operation. The statement that a blowing engine could go from 10 lb. pressure to 30 lb. pressure dealt with extremes that did not occur in ordinary blowing, but distinct cases were known where a blowing engine normally

[1] To be published in the March issue of The Journal.

[2] Blast Furnace Department, Bethlehem Steel Co., South Bethlehem, Pa.

operating at 12 to 15 lb. went all the way up to 30 lb. when the clearance tightened up.

Mr. Gantt Discusses Expenses and Costs

H. L. Gantt then presented his paper on Expenses and Costs, in which he claimed that there were in every manufacturing enterprise expenses which did not contribute either directly or indirectly to the production of goods. Such expenses, he maintained, should not be considered as a part of the legitimate cost of the goods, but should be kept in a separate account. Further, the expenses in this account should be classified according to their various causes, and strenuous efforts should be made to eliminate these causes and thereby reduce this non-productive expense. This was particularly important in time of war, when all of our energy was needed for productive purposes.

Frederick A. Alden, in a written discussion of Mr. Gantt's paper, said he thought that one of the most vital causes of idleness of machinery was apt to be the fact that one machine might be adapted for but one or a few operations, while if a more universal type of machine had been purchased other operations might be performed on it. In advising upon the exploitation of a new manufacture, he had always maintained that unless such manufacture was of a major type, it would be one which would cause idleness at times due to lack of demand for the finished article, as most articles had a variable demand. Hence, that unless a variety of articles could be manufactured upon the same machine with a slightly different setting, the manufacture of the article in question would not be a paying proposition. Many companies made but one or a few lines of goods or fabrications, and in consequence always had certain machinery idle at times. One remedy for this idleness would be the manufacture of auxiliary products or by-products.

Many factories had machinery and stock idle which had ceased to be useful through breakage and wearing out of the former and no demand for the latter. He felt strongly that anything which could not be used within a reasonably short time should be sold, if salable, junked if not salable, and if neither of the above were possible, converted into fuel or disposed of as rubbish. There was too great a tendency to hold on to machinery and material hoping that it might be used some day. Considering the cost of such holding, which is the cost of idleness, including storage costs, use of valuable space, further depreciation, loss of interest on investment, a rapid and early conversion into available cash should always be the rule, based upon immediate possibilities as stated.

Major Frank B. Gilbreth commended the paper in unstinted terms. The principle Mr. Gantt had called attention to, he said, carried a little further, was identical with the scheme of dumping American manufactures abroad. In other words, the average cost accountant, if let alone, would so sprinkle certain costs that he could go to the management, particularly to the financial management, and boast of the fact that he had but a trifling amount remaining undistributed somewhere. That might be a proof of great merit among cost accountants, that they had distributed and redistributed cost items, but the more they were distributed and redistributed improperly, the more the self-deception, and if a plan had been laid out for the distribution of overhead expenses among various items for a normal business, how could more money be made by making more than it was originally intended to make and not distribute or redistribute any part of the overhead expense?

Major Gilbreth then described an improved arrangement of bulletin board that would make possible a quick judgment on this matter, by means of which the head of a sales department with a single glance could tell which of a certain bank of machines that had been brought together on account of their mnemonic classification, were going to run out of work, and could then go out and telephone to neighboring shops for immediate work, if necessary, and take on jobs which would keep down the idle time, as Mr. Gantt had pointed out. The board also showed the names of those men handling machines who had been proved to be the most efficient on them, which seemed to definitely help out the employment department in "evenizing" the necessary shifts that had to be made among the machines.

Henry Hess disagreed with the author that the matter under discussion was primarily a question to be solved by engineers rather than by financiers. There was a time in the history industries, he said, when there was a sharp line of cleavage between the shop, the so-called production end, and the office, usually termed the non-productive division, each managed by specialists. That was the heyday of the engineer and producer, and the financier, as separate people. If that period had not actually passed, it certainly was passing, and it was rather unfortunate that the author should apparently reaffirm this unfortunate division.

There should be no consideration of an important question of cost of production by the engineer as an engineer, or by the financier, as a financier. Any such question must be considered by both. The broad statement was made that certain expenses due to relative inefficiency of production were not part of the legitimate cost of goods. There always would be and must be some not absolutely necessary costs, the amount varying with relative efficiency of business management in a given business, and that cost must be and would be passed on to the consumer. An increase caused by an undue amount of such cost would simply lead to a refusal on the part of the purchaser to buy the goods, and therefore the consumer thus automatically applied the necessary corrective.

So far as Mr. Gantt's suggestion involved a careful subdivision of costs, it was wholly admirable, provided that each such subdivision was for the purpose of its careful scanning, with a view to its reduction. It was this reduction that was of importance, regardless of the allocation of any element of cost to any group of accounts.

Adolph L. De Leeuw, referring to Mr. Gantt's statement that there was no great difficulty about getting the expense for material and expense for labor, asked if, say, 30,000 tons of pig iron were bought at \$14 a ton, and a year later 20,000 tons were left, and the price of pig iron had gone up to \$58 a ton, what was the expense of the material? If it was said that the material should be charged at \$14 a ton, well and good; but if the 30,000 tons gave out, and 30,000 tons were purchased at \$58 per ton, on the expectation that it would go up to \$80 in the near future, but instead the price went down again to \$14 a ton, then what would be the price of the material? \$58? But who would buy the product on the basis of \$58 for pig iron?

There was no question about the advisability or the desirability of keeping a plant working, but in the plant with which he was connected there were large portions of the buildings devoted entirely to special operations, and each machine used was absolutely good for one operation and one piece and for nothing else. Furthermore, even if they did not increase the capacity, and should run the shop 50 hours a week, they all knew there were 168 hours in the week. Was this machinery

idle for the other 118 hours? If it was and the shop ran overtime, then was it idle or negatively idle?

A. L. Williston said that most manufacturers he had come in contact with seemed to regard overhead as one of those mysterious things that could not be analyzed, that it was necessarily a constant. It was not a constant, and Mr. Gantt had called attention to one of the variables that affected it. A very large percentage of all the confusion in the matter of accounting had been due to the fact that we were in the habit of expressing costs in figures and we had been confused in thinking that costs which were expressed in figures were a constant. There was hardly a single item of cost in any manufacturing operation that was a constant, and we should get into the habit of thinking of these things as variables, studying the laws of their variation, instead of thinking of them as constants and trying to memorize those constants.

Walter N. Polakov thought that the points raised by previous discussers were relatively unimportant compared with the big question: If it costs us something to do nothing, why shall society at large pay for our inefficiency and for our idleness? In England and France and Italy the slogan now was, "The idle hand assists the enemy," and we might equally well say that the idle machine assisted the enemy, because the fact was that if we left our machinery idle or inoperative, the results were the same as those due to the sinking of our ships, the blowing up of munition factories or the burning of grain elevators.

His work in the public-utility and power-plant field had been such as to make him believe the idleness question was just as important, if not more so, in that particular branch of industry as in others with which he was not so familiar. Mr. Polakov then had thrown on the screen a chart representing averages obtained from some seventeen power plants and showing that but half the capacity was utilized on the average daily run.

Carl G. Barth called attention to the fact that twenty-five years ago F. W. Taylor had covered everything that had been brought up by the previous speakers and that he had done as much for accounting as he had in the management of the plant and in other details. It was his hope that he could eventually give the world the benefit of what Mr. Taylor did.

H. M. Wilcox said that in the standardization and wage-payment systems which had been developed, attention had been concentrated almost entirely on productive labor.

He could say from personal experience that a very complete analysis of idle-machine time had shown the Winchester Repeating Arms Co. where it could eliminate a great deal of time, and in a great many instances they had been able to establish standards and definite forms of wage payments other than day pay to compensate their so-called non-productive workers for what they had done in limiting the idle time of equipment and organization.

As to the effect of idle-machine time on cost, from their present data, covering six or eight months, they had plotted the curve shown in Fig. 1, and had found that the average curve drawn through all the points, amounting to several hundred, was an equilateral hyperbola. The shop factor was taken as the actual burden earned by the machinery at machinery-hour rates divided by the actual burden charged against the various shops. The first 5 per cent of idleness, it would seem, had little effect on the cost; the next 10 per cent had more, and the more inactive the machinery became the more rapid the losses were. He believed that in the reconstruction period after the war this question of idle-machine time would be one of very vital importance.

Carl G. Barth said that he considered the most vital thing in cost was that it be known where every penny went. The first thing was to be able absolutely to tie up every expense, no matter how it was done. Most people, however, used an overhead expense factor that they had inherited.

His method was to get the most simple distribution of the expenses, without any analysis whatever — put it all on wages, but tie up the cost so that he would have the whole burden. Next, he took the expense item for each department, in labor. Then he found a more equitable way of dividing the more general expenses of the various manufacturing departments, so that each department was separated, and then they were responsible for what they got from the office and the other auxiliary departments. Then he went through the cost on the basis that each problem was a whole, and finally, in the last refinement, he distributed it.

The author had said that he did not know what to do with the expense of idleness. In his opinion he would have to charge it to profit and loss; and nothing else could be done with it.

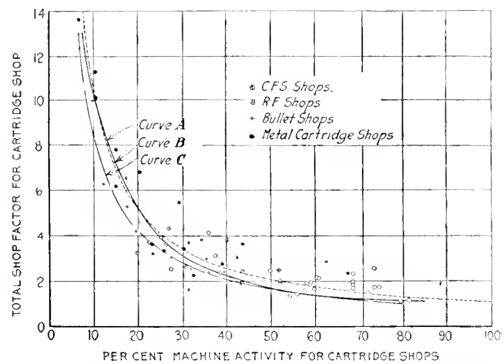

Fig. 1 Relation Between Machine Activity and Total Factor for Cartridge Shops

(48 hours per week = 100 per cent activity)
Curve A:—Plotted from monthly reports of May, June and July, 1917.
Curve B:—Geometric equilateral hyperbola of equation $xy=100$, where x=per cent machine activity and y=shop factor.
Curve C:—Theoretical equilateral hyperbola of equation $xy=80$.

Mr. Gantt, in closing, said he had suggested the year before that the expense of idleness might be put in profit and loss, as mentioned by Mr. Barth. He did not care whether this was done or not. If one man put it on profit and loss and the other put it on his product and based his selling price on the cost of his product and the other did not, the one who did not would not sell his goods in competition with the other man, and then he would have more of his plant idle and more of this item to consider.

Two years ago a man had told him the cost on a certain article was 30 cents a dozen and that they could be bought for 26 cents a dozen, and had asked him whether to buy them or make them. The cost consisted of 8 cents a dozen for material, 10 cents for labor and 12 cents for overhead, and the plant was running one-third full. On being told that the overhead if the plant ran full would be about 5 cents a dozen, he had said to the man that if the plant was run full the cost would be 23 cents instead of 30. A competitor running full time

would have less cost and so would sell where he could not, making the man's cost go up more because he would have still more idle time.

Mr. Hess had been more fortunate than he had in the fact that the financiers had not interfered with the operation of his plant. His experience was that as soon as the engineer began to show the plant was being interfered with by the financier who did not know anything about manufacturing, then the trouble began.

If we could show those expenses attributable to management and mismanagement, and show where they belonged, instead of placing them on the workmen, we could soon make the salesmen and the financiers sit up and take notice. It had been done in a number of cases, and no one who was using this method would think of giving it up.

So high an authority as the Chief Constructor of the United States Navy, referring to his paper presented last year on this general subject, had said that it was the only system he knew anything about which would do justice to the arsenals and the navy yards.

In regard to Mr. De Leeuw's questions, no general answer could be made. There were some present who had been wrestling with these questions for the past two years, and they were satisfied with the answers they had reached. The answer would not be the same in different plants. He would not think of a set of rules to go by, for rules without fundamental principles were as misleading as they could be. If we got the fundamental principles right and could not work out rules, we were on the wrong job. If we worked out the fundamental principles and could not apply them, we must get something to help us. In the past we had tried to run things according to precedent and by rules; and we had reached the end of it. The old business schemes did not work any longer. It was necessary for us to eliminate waste and expense, and not cover them in the product and give them to the public to digest. If we attempted to digest them we should be beaten by Germany.

A SESSION ON TEXTILE SUBJECTS

With Authoritative Papers on Labor-Turnover Records, Accident Prevention, and Moisture Content of Textiles, and Discussions by Textile Men.

THE Textile Session of the Annual Meeting was held on Thursday, December 6, at 2:30 p.m., under the auspices of the Society's Sub-Committee on Textiles, Vice-President Charles T. Plunkett acting as chairman. Three papers were presented at this session, namely:

LABOR-TURNOVER RECORDS AND THE LABOR PROBLEM, Richard B. Gregg.

ACCIDENT PREVENTION IN THE TEXTILE INDUSTRY, David S. Beyer.

THE MOISTURE CONTENT OF TEXTILES AND SOME OF ITS EFFECTS, William D. Hartshorne.

MR. GREGG PRESENTS HIS PAPER

In the first of the papers to be read, Mr. Gregg considered the various causes that have given rise to the serious problem involved in the shifting of workers from one factory to another, and urged that the same rational methods of analysis be employed in its solution that have long applied in the cases of production and factory-operation problems.

Albert L. Pearson, commenting on the author's mention of illumination of work place and amount of accident risk as two important causes for labor turnover, wrote that in designing a lighting system the aim should be to have illumination which would approach, as nearly as possible, daylight efficiency in production. As a result the workmen would be better satisfied and the amount of second-quality work would be reduced. Good lighting was conducive to cleanliness and helped to prevent accidents. Moreover, a well-lighted place was attractive, while a dimly or poorly lighted place was just the reverse.

Lewis Maxfield wrote that as long as any concern persisted in maintaining low wages, long hours of service and unsanitary factory conditions, it would experience a large labor turnover because its employees would be continually leaving for factories where the conditions were the reverse of those mentioned. There was no doubt but what the labor problem was what it was today just because we had failed to remember at all times that the laborer was human and should be treated accordingly. It was indeed true that industrial conditions as affecting the worker were changing for the better, but there still remained a considerable field for improvements.

Walter M. Kidder wrote that the aim of all investigation of the subject under discussion was to disclose the cause for the rate of labor turnover. The best experience of those who had given the subject ample study was that foremen were not likely to ascertain the real reason for quitting in a large number of cases, or to place it on record uncolored by their own attitude respecting each of them. It was vital to get at the real reason in order to bring it under future control. In some cases it could be learned by some other person much more dependably, for example, by the employment agent, or superintendent, or paymaster, or by some officer or member of the firm who had a faculty for gaining the confidence of employees. In every case of voluntary quitting this step should be taken, even though it added to the burden of some busy man to listen to the stories he must hear in order to sift out the basic truth of the real cause.

George H. Perkins cited a remarkable instance of low turnover in the mill of the Naumkeag Steam Cotton Co. of Salem, Mass., which was destroyed by fire in 1914; 20 months later, shortly after starting the rebuilt mills, it was found that 72 per cent of the 1600 old employees were at work in them.

Lawrence W. Wallace said that the manufacturing plant with which he was connected had worked out a comprehensive program for combating the problem of labor turnover, and that in spite of the chaotic conditions at the present time and the unrest, in recent weeks the tendency in their labor-turnover curve had been downward. He would suggest that valuable information would be found on this subject in the Annals of the American Academy of Political and Social Sciences, and a great deal of the material they had in their program came as suggestions from reading in those publications.

W. D. Hartshorne thought that the sum mentioned by the author for the cost of training a spinner was very small, and the method of training might account for it. As a rule, the

method of training spinners was to put them on a job and let them go at it, and this generally involved a great deal of cost.

Arthur C. Jackson said that, on the theory that the proper place to draw workers from was the immediate vicinity of the plant, his company was making an industrial census of the community within a radius of one mile from the plant, and advertising the desirability of working within walking distance of home and in a shop that had certain attractions which they felt theirs had. In this way they hoped to reduce the turnover somewhat.

Herbert M. Wilcox thought that in formulating a constructive program for reducing labor turnover, an important factor was recognition of length of service. This should be not only in the form of wage remuneration, but in the conferring of soms sort of stripe or medal, so that old employees would hold a more honorable position with the organization than men who had been employed a comparatively short length of time.

Charles H. Bigelow said that the company with which he was connected was now furnishing every one of its 1000 employees with a paid-up insurance policy, based on six months' employment, of $500. For each year they had been in the service $100 was added, up to $1000. That, he thought, would keep down the labor turnover to some extent, because a man got some benefit by staying with the concern. The company carried the policy as long as the man remained in their employ.

Arthur Brewer said that his concern, the Bridgeport Brass Company, had adopted the same scheme of life insurance and had also insured employees against accidents which might occur within or without the shop, and also in the case of sickness.

By way of addition to Mr. Wallace's remarks, the author stated that both the May 1916 and May 1917 issues of the Annals of the American Academy of Political and Social Science contained excellent material on methods of reducing turnover. This was an aspect of the problem that his paper did not attempt to deal with.

R. F. Burnham[1] said that in his plant, employing about 5000 men, in the last two years and a half they had taken on over 20,000 men, the turnover had been that great. Recently they had adopted the method of placing all the labor under an employment manager, who had the authority for hiring and discharging all men. If a man sent out to a foreman did not suit the latter, the man was not discharged, but was sent back to the employment manager and put in another department. If he did not fit there, they kept on trying him in various places, and finally when the right groove was found the man stayed. In that way they had reduced their labor turnover fifty per cent by endeavoring to place the man in the work he was adapted for.

When a new man came into a department, the foreman was instructed to give him some attention and teach him what his work consisted of—to do a little welfare work, a little uplift work—and make the man feel that he was a part of the organization. By doing that they made the men content. After two years of service the men received a certain bonus.

Welfare work, visiting nurses, recreation halls, etc., were necessary for the men, especially at the present time when they had a disposition to rove somewhat.

[1] Hercules Powder Co., Kenvil, N. J.

Ambrose B. Dean gave interesting details of a part-time method of vocational training successfully adopted in a textile-manufacturing city by the Board of Education, of which he is a member. Those students that had been in the classroom for three days, or a week, then went, under the school authorities, into the mills, and along with the employees there put into practice, as far as possible, the theories that had been taught in the classroom; and those who were already in the mill would then return to the schoolroom for their three-day stay or corresponding period.

In many of the mills men were discovered who were more or less advanced in years, who had never had the opportunity of scholastic education, many of whom could not read a blueprint, and many of whom did not understand a simple formula. Attempts made to get them into the regular vocational schools were not successful, owing to the sensitiveness of the older men in regard to associating with younger men in school work. This situation was successfully met by organizing a class for the employees of a given mill, and, under the direction of the school authorities, appointing a college-graduate employee of the mill as teacher of the class, the mill owner contributing the time of this teacher and furnishing the classroom.

E. B. Smith said that in the case of machinist training, those who had graduated from apprentice schools, or otherwise, he had found the labor turnover depended on one feature—selling the operator to the company. If the manager, foreman, gang boss, leader or monitor, failed to sell each operator to the producer, the result would be a large turnover.

The turnover caused the most expense in the case of the old experienced hands, who usually had a psychological reason plus a financial reason for their actions in relation to the company. The psychological reason lay in the training of the old hand and the financial reason in the pay envelope. Work going to an operator from a previous operation in a defective condition was the cause of much trouble, and that was due to the improper training of the operator performing the previous work. It all resolved down to the question of the individual operator under consideration: Was he or she trained right?

They had found that the principal way in which to hold the old operator was to let the company appreciate he or she was an old operator. Rewards and badges of merit were good, a Christmas envelope of five per cent of the yearly wages was also good. But in any case the operator must be contented and satisfied or he would leave.

Their practice was to break the operator in first and then to try to fit the round pegs in the round holes. They had found on a particular operation where ten weeks was ordinarily required, that intensive supervision brought it down to ten days. This meant that we must employ these intensive methods if we were to fit the female for the work which the male had been doing. The males were going to the front and the females were taking their places, and we must analyze step by step each operation and cut out the heavy manual part of the work where we could, in order that the female could take it up, and then we must train her and treat her so that she would be satisfied. The chief thing was to have the operator satisfied with the pay envelope, and to get that the operator must be trained right, the machine must be right, and the work coming from the machine must be right.

P. A. McKittrick said that the company with which he was connected built textile machinery, and in one of their plants

where about 1600 workers were employed they found that the labor turnover was about 120 per cent, nearly all of it in the first year. If they could hold the man a year they could hold him then as a more or less permanent employee.

During the last two years it had been necessary to make many general advances in wages, and in the last advance they adopted the plan of giving each man in their employ up to three months extra pay each month at the rate of 4 per cent of his monthly wages; from three to six months he would get 6 per cent; from six to nine months, 8 per cent; from nine to twelve months, 10 per cent; and in the case of those employed over twelve months, 12 per cent. They had put the plan into operation just at the time when the Liberty Loan was being exploited, and as a result 1300 of their men had subscribed about $65,000, using this extra pay to pay for their bonds. They were quite sure the plan would cut down their yearly turnover.

The chairman called attention to the fact that the author had said that the question had been asked: Will it be wiser to leave the broad problem of control of labor turnover entirely in the hands of employers, or should the state or labor unions have a voice in the control? and inquired if that was an intimation that the employer had had the control in his hands, or that it should be left there.

Mr. Gregg, in replying to the chairman's question, said that he did not think the employer had control now, but as time went on he would get it more and more, and he was personally inclined to think that with the development of employment exchanges, which were very probably coming in this country as they had come in England and in the Continental countries, we may see a method of control of labor turnover for specified districts. That system might be developed by the state, but probably the labor unions would have a voice in its development.

He urged that care be taken to remember that the greater part of labor turnover is not a malady in itself, but is important primarily as a symptom of dissatisfaction or discontent.

Mr. Beyer Discusses Accident Prevention in the Textile Industry

In presenting his paper, Mr. Beyer emphasized the fact that the textile plants had an abnormally high proportion of mechanical accidents, giving the reasons therefor. He then discussed fully various devices for safeguarding existing and new machinery, and presented for consideration a set of safety standards in actual use in a textile plant which specify the safety equipment for gears, sprockets, dangerous projections, pickers, cards, doublers, drawing, winding, ring spinning and twisting frames, looms, etc.

John W. Upp, in a written discussion, said that few realized the vast number of minor accidents that occurred in our workshops and factories, or had any adequate conception of the aggregate cost of such accidents until they made up their yearly reports or looked at tabulations of accidents such as were presented in Mr. Beyer's paper. As we gained in experience, we found that the majority of these accidents were preventable if we installed safety appliances and then saw that these appliances were guarded and kept in place after the first installation.

He was very much pleased to find that the author recommended those machine guards which were interlocking, and that they compelled the operators to use them. Belts, fortunately, were beginning to give way to direct drive, but there were still enough of them in use to warrant special attention being given to the guarding of machine belts, for they were even more hazardous to the woman worker than gears.

In the various factories in which he was interested they had found their safety-committee work the most profitable single undertaking with which they dealt. They gave the committee complete authority, so that they could discipline those operators who jeopardized their own interests, or those of others, when they removed guards, and they analyzed each accident report and did not dispose of it until they had indicated a means of prevention of similar accidents in the future.

George R. Wadleigh said that, in regard to the belting, particularly in the spinning room, which is equipped with what is known as the Lockwood, Greene drive, it seemed impossible in that case to run a belt guard from the floor up to a height of 6 ft. This, in his opinion, was more or less unnecessary, but at the same time it was the law in some of the states. Another requirement in several of the states was a screen around large belts. In their records of accidents going back five years, in a number of textile mills they had only one case of any one being injured by falling against a main driving belt.

The author, replying to Mr. Wadleigh, said that he had never been in sympathy with the 6- or 7-ft. height specified for the belt guard in some cases. He had asked a number of safety engineers if they had ever known of an accident in a case of a belt guard which was run to a height of 3 ft. 6 in. from the floor, and had never been able to find a record of such an accident which could have been prevented by the higher guard. A committee of engineers of the insurance companies he was connected with was working on this matter, and had called a conference to be held December 11 in New York, to which representatives from the New York, Massachusetts, Pennsylvania, New Jersey, Wisconsin and other labor departments were invited, in an effort to get uniform standards adopted in all these states which would be practicable and would not go too far, as it was now felt some of these standards did. He thought it would be of great value to the employers in the different states and quite a step forward if this could be done.

W. G. Duncan said that manufacturers had had a great deal of trouble, not only in regard to the lack of uniformity of standards between one state and another, but between the various whims of the different state inspectors. He thought also the legislatures had made a mistake in passing laws which were entirely too mandatory, and leaving to the safety department of the state or the chief engineers and inspectors no room for the exercise of any judgment whatever. His company had been very much annoyed in putting on a set of guards which were satisfactory to the state department one year, and then being told the next year that they were worse than useless, and must be replaced by something else. It seemed to him that the first step in this matter was to bring about a standardization of safety devices.

P. A. McKittrick emphasized the need for standards, stating that his company sold machinery to manufacturers in nearly every state in the Union and practically every country in the world, and that it was necessary for them to have very many sets of patterns—what was good and sufficient for one was not for another. This burden was entirely on the ma-

chinery builder, because his company had never succeeded in getting any recompense for the additional work.

D. E. Douty told of his difficulties in endeavoring to comply with the requirements of an insurance inspector in a plant of moderate size, and suggested that the standardization of such officials would be an excellent thing.

Richard B. Gregg[1] asked the author whether there were any figures which showed the distribution of accidents throughout the day and week: that was to say, were there more accidents the first thing on Monday morning than there were the first thing, say, on Thursday morning? Were there any more accidents at the end of the working period along at 11.30 or 12 o'clock, or 5.30 or 6 o'clock, than there were at other times in the day? He thought that was sometimes an element in the human factor which was overlooked, as sometimes we ascribed accidents to sheer carelessness which were really due to fatigue of the operator.

Allan D. Risteen said, in reply to a previous speaker, that all insurance companies certainly did need a standardization of inspectors, for inspection was largely a question of standardization. It was the custom of his company to have their inspectors, after they had visited a plant, indicate in their reports about how soon they thought the plant ought to be visited again, and if an inspector found it necessary to go to a plant every six or eight weeks, he did not know whether he thought it was altogether the fault of the inspector or not.

William D. Hartshorne said that in regard to the time of day accidents occurred, for some 10 or 15 years he was connected with the Arlington Mills at Lawrence, Mass., where they kept an accurate account of every accident, the hour at which it occurred, the cause of it, and every detail about it, and he would say that there was no question but what there was a material difference in the nature of the accidents which occurred at different hours of the day, and that there were many accidents which occurred on Monday morning which, taken in connection with the circumstances which surrounded them, were certainly well worthy of special consideration.

S. C. Coey said that he had made somewhat of a study of the time of day of accidents in the steel industry, and found that in the case of the Youngstown Sheet & Tube Co. the greatest number came along in the morning hours, about 10.30, and that thereafter another peak in the accidents occurred in the afternoon. The peculiar thing about this time of greatest accidents was the fact that it was at the same hour as the peak in the power curve, showing that the rate of doing work in the plant and the number of accidents had a certain definite relation. He had been connected with Celluloid Company of Newark for the last few months, and had had a curve drawn up along the same lines, which showed the same general results in that industry as in the steel industry.

Allan D. Risteen said that in making reports of accidents, where the hour was not recorded at once, there was a certain psychological factor that influenced the man who was filling out the blank not to set the hour at opening or closing time, but somewhere in between. He did not mean to say that that caused the curve to have that characteristic, but there was certainly an influence of that kind which tended to emphasize the curve and should be considered when statistics were being studied.

[1] 814 Flatiron Bldg., New York City.

Mr. Beyer, in closing, said that he desired to speak a word in behalf of the machinery manufacturer, and that was this: that the man who used the machinery was paying the money, and he was really the one who held the key to the situation. They had found that in the U. S. Steel Corporation—when they got out definite specifications for new machinery, showing what they wanted, the manufacturer gave it to them, but until they adopted that plan they had quite a variety of results. That would be taken care of by the definite standards suggested in the paper—the machinery builder would know what he had to give, and the employer would be assisted in securing the best.

The question of an overhead belt guard had been raised, and he knew of one or two cases of serious injury or death from the breaking of overhead belts. That did not happen often in any one plant, but where there were several thousand plants located in each state a number of accidents occurred every year, and he thought it was desirable to guard 12-in. belts or over—when they were fast-running belts.

The question of standardization was largely up to the insurance inspector and state inspectors in getting uniform results, but he thought the Society could exercise an excellent influence in bringing about a more general uniformity in standardization.

The question of the time of day at which accidents occurred had been pretty well discussed. He had made a number of such analyses and studied a good many others, and found that almost invariably both in this country and abroad the accident rate increased gradually until within about an hour of the end of the turn, both in the forenoon and afternoon, and then dropped off. There it seemed that the employees got their second wind and began to pick up a little and look toward the closing of the day. That was such a constant condition that he hardly thought it could be due to the makeup of the report, and he thought it did represent the psychological and physical condition of the employee. In regard to a relation between the peak of the load and the frequency of accidents, the load in the textile industry was apt to be pretty even, so that there was not the variation due to the human factor that would be found, say, in the steel industry.

Mr. Hartshorne Reads Paper on Moisture Content of Textiles

In the third paper to be presented, Mr. Hartshorne discussed at length the effect of moisture content on the weight of textile materials, and set forth certain laws governing the regain in cotton and worsted which he had developed after an extended period of investigation, together with numerous charts and tables for facilitating calculations.

Walter M. Kidder, in a written communication, commended the paper highly. He said that the author raised but did not answer one question that was of the greatest importance because of the magnitude of the cotton industry in this country, namely, whether or not it was of advantage to increase the humidity of the air in the successive processes of manufacturing. It was a matter of importance to have this determined authoritatively.

The effect upon quality which the author showed results from varying conditions of moisture constituted a powerful argument for the maintenance of uniformity in each department of the particular condition which was most advantageous. To accomplish this in practice called for intelligent application of the law that he had enunciated, but also would

require the exercise of engineering skill in many cases, for the flow of air currents within some factories extended throughout the entire structure, and differences in degree of humidity in different departments were correspondingly difficult to maintain. It was also true that it was difficult to maintain uniformity of humidity in all parts of one room under the best conditions.

Willis H. Carrier thought that Mr. Hartshorne's paper had gone into the subject with extreme thoroughness, and that it was a contribution to the subject which would be permanent, largely because of the methods he had adopted.

The subject, however, had a very much wider bearing on paper. It was very important, he thought, perhaps, even more important than, in the case of textiles, because in the subsequent treatment of paper and sizing and calendering, the moisture content had to be procured for the best results with great accuracy. The same was true of tobacco and practically all hygroscopic substances where moisture content was important in the process.

There was one product he had in mind where the installation was bad, the material was wet, and they wanted to dry it down to 10 per cent moisture. But if they had sold it on the basis of 10 per cent moisture, it would have been at a loss, so finally the moisture was reduced to 0.25 per cent, which was made possible by his knowledge of the laws enunciated by Mr. Hartshorne. That was a very important application, for that one-half or one per cent they got in the week's production, something like $100,000, meant $1000 or so.

The effects of differences in vapor pressure were very important in calculating rates of drying which occurred in various hygroscopic substances, and it would be desirable if Mr. Hartshorne would carry out his investigations at higher temperatures, temperatures beyond 100 degrees, where a great deal of the drying was done, in order that the laws could be investigated there as well as in the normal temperatures of the room.

Mr. Hartshorne, in closing, thanked the previous speaker for his comments. The question of the relation to drying, he thought, was an exceedingly important one, and he had mentioned it in the paper in several places as being affected in ways which might not be understood. That subject needed more investigation, and he would be very glad to undertake it if he had a research laboratory available.

Referring to Mr. Kidder's communication, the question to which he alluded as having been raised but not answered, Mr. Hartshorne agreed was very important, and he was of the opinion that it needed careful investigation under practically workable conditions, with complete understanding and controlled knowledge of results, to demonstrate what are the best obtainable effects both as to quality and quantity of product. It could be done, and for the benefit of the cotton industry it ought to be done authoritatively.

WORK OF THE BOILER CODE COMMITTEE

The Boiler Code Committee meets monthly for the purpose of considering communications relative to the Boiler Code. Any one desiring information as to the application of the Code is requested to communicate with the Secretary of the Committee, Mr. C. W. Obert, 29 West 39th St., New York City.

The procedure of the Committee in handling the cases is as follows: All inquiries must be in written form before they are accepted for consideration. Copies are sent by the Secretary of the Committee to all of the members of the Committee. The interpretation, in the form of a reply, is then prepared by the Committee and passed upon at a regular meeting of the Committee. This interpretation is later submitted to the Council of the Society for approval, after which it is issued to the inquirer and simultaneously published in The Journal, in order that any one interested may readily secure the latest information concerning the interpretation.

Below are given the interpretations of the Committee in Cases Nos. 177-180, inclusive, as formulated at the meeting of November 9, and approved by the Council on December 4, 1917, and the interpretations of the Committee in Cases Nos. 181-184 inclusive, as formulated at the meeting of December 6, 1917, and approved by the Council on January 18, 1918. In this report, as previously, the names of inquirers have been omitted.

Case No. 177

Inquiry: Is the type of removable dome as shown in Fig. 13 for use on h.r.t. boilers permissible under the rules of the Boiler Code, or is it necessary that this dome be attached direct to the shell with a double-riveted flange for pressures over 100 lb.?

Reply: The construction shown in Fig. 13 is considered as a steam boiler drum and not a boiler dome, and therefore does not come under Par. 194 of the Boiler Code.

Case No. 178

Inquiry: An interpretation is requested of the application of Par. 253 to the drilling of rivet holes in crowfoot braces. Is it permissible to punch holes in the shell full size where the brace is fastened thereto?

Reply: It has been proposed to revise Par. 253 to read as follows:

> 253 *Drilling of Holes.* All rivet holes and staybolt holes and holes in braces and lugs shall be drilled full size, or they may be punched not to exceed $\frac{1}{4}$ in. less than full diameter for material over $\frac{5}{16}$ in. in

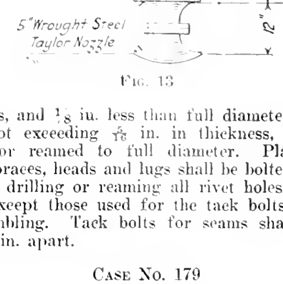

Fig. 13

> thickness, and $\frac{1}{8}$ in. less than full diameter for material not exceeding $\frac{5}{16}$ in. in thickness, and then drilled or reamed to full diameter. Plates, butt straps, braces, heads and lugs shall be bolted in position for drilling or reaming all rivet holes in boiler plates except those used for the tack bolts required in assembling. Tack bolts for seams shall be not over 12 in. apart.

Case No. 179

Inquiry: In the use of steel castings for the construction of locomotive boilers, what class shall be used under the speci-

fications for steel castings given in the A.S.M.E. Boiler Code?

Reply: It is the opinion of the Committee that unless the Code specifically distinguishes between Class A and Class B, either class is permissible.

Case No. 180

Inquiry: Is it permissible when calculating the maximum allowable pressure on a furnace of a vertical tubular boiler that is staybolted and less than 38 in. in diameter, to determine the pressure that would be allowed under Par. 239 for a plain furnace, and then add the pressure which would be allowed according to Par. 199 for the supporting value of staybolts?

Reply: It is the opinion of the Boiler Code Committee that your inquiry is answered by the reply in Case No. 57 and the reply in Case No. 113*a*.

Case No. 181

Inquiry: Is Par. 239 of the Boiler Code correct, as interpreted in Case No. 22, in its application to plain cylindrical furnaces? Under the interpretation of Case No. 22, a Lancashire type boiler with a single furnace 30 ft. long by 4 ft. diameter, built of 11/16 in. sheets, would be allowed a working pressure of only 29 lb.

Reply: There is no rule in the Code for the calculation of the pressure to be allowed on this particular construction, as Par. 239 is limited in its application to furnaces whose length is not over six diameters. If plain furnaces of these large dimensions are to be used without Adamson rings or other reinforcements, they must be stayed as specified in Par. 240.

Case No. 182
(Annulled)

Case No. 183

Inquiry: Is the rule in the Boiler Code requiring double stop valves on the steam pipes of boilers set in battery applicable to boilers of the locomotive type where no openings are made for entering them and the danger of scalding any one working inside does not exist?

Reply: It is the opinion of the Committee that Par. 303 does not make specific reference to any particular type of boiler, and therefore fully answers this inquiry.

Case No. 184

Inquiry: It is desired to use, solely for heating purposes, a h.r.t. boiler with 4 in. flange for connecting the gravity returns from the heating system. Is this allowable, or does a boiler of this construction come under the limitation of the Code as to size of blow off?

Reply: If the construction is to be solely used for low-pressure heating purposes, the rules for heating boilers apply, and no limitation in size of blow-off is required for that class of boiler (see Par. 364). If, however, this boiler were to be used for power purposes, it would be necessary to limit the blow-off size as described by Par. 308.

CORRESPONDENCE

Contributions to the Correspondence Departments of The Journal by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in The Journal, or brief articles of current interest to mechanical engineers.

Scheme of Gaging for Screwed Parts

To the Editor:

The trend of machine design, as found in the bicycle, automobile and airplane, indicates an increasing demand for better screw-thread fits.

This is not only desirable for standard bolts and nuts, but

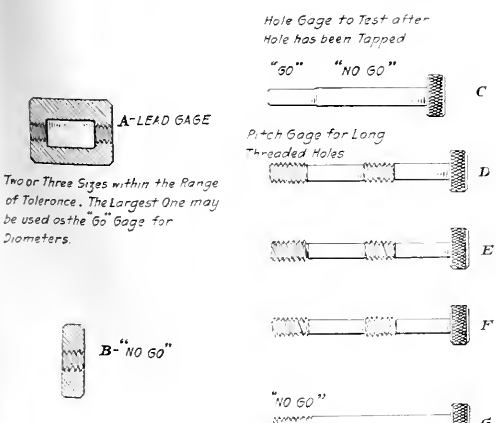

Fig. 1 System of Gages for Screw Parts

it is imperative for screw threads that enter into the design of a machine in which the greatest strength for given dimensions is required.

One of the steps in betterment of the lead of die-cut screws is set forth in a paper by the writer, entitled A Screw Die for the Turret Lathe, Trans. Am. Soc. M. E., Vol. 19, p. 77.

We know how high may be the price paid for a poor fit in an obscure place of this kind, especially in the life of the flier, but if such carelessness runs through all the work, it may actually result in turning the tide of battles and final results of the present war. The contemplation of the full significance of this and other elements of machine design keeps us continuously keyed up to the keenest appreciation of our obligations.

Much advance has been made in the production and gaging of the screw, but the nut or internal thread has not shared in this advance.

The flow of metal under stress of the so-called wrench fit makes it possible in a moderate length of contact to force a nut over a screw in which there has been a marked difference in both the form and lead of thread. Many screw-thread fits that are most satisfactory in common practice do not give an even distribution of the working stress. As a matter of fact, where there is a difference in lead, the stress within the length of the nut may be added to the working stress.

Many ways have been considered for the improvement of the internal thread, but our practice is still very unsatisfactory, especially when viewed from the needs of the airplane.

The purpose of this communication is to emphasize the need of greater care in cutting internal threads and to suggest a system of gaging that will give a more definite indication of the character of the fit. The importance of greater care in cutting internal threads is not only from the needs of more dependable product, but in keeping with modern practice it may even reduce the cost of product.

The system of inspection should give most careful scrutiny to the means and methods for producing the work. This is particularly necessary in connection with internal threads in which the length and diameter are so proportioned that it is impossible to see the condition of the thread.

We should know the pitch and lead of the tap, and we should also know the lead and other dimensions of the work produced by the tap.

The leading end of the tap may produce a larger hole than the part following, so that the whole length of the tap may not serve to control the lead. In fact, it is known that the first few threads of a tap generally determine the advance, and that there may be a very strained condition if the contact of the following threads conflicts with the tendency of the leading threads.

Experiments in which the shank of a tap has been threaded to fit a nut in order to insure the advance of the cutting end of the tap in the work, have shown that even with a short thread in the cutting part of the tap, well backed off, there is a conflict between the control of the lead screw on the shank of the tap and the natural advance of the cutting end, so that any lost motion in the lead screw or any yielding between the lead screw and the cutting end results in a similar degree of error in lead of thread produced in the nut.

In die and tap making it is found that the final hardening of the cutting edge of the die and the tap results in changes that are not uniform, and that it is desirable, in the production of work in which the greatest strength is required for a given weight, to use only those dies and taps that are known from the first to produce satisfactory results, and the product of these should be inspected not only at first but from time to time during their use to insure their maintenance of accuracy of lead. The first inspection may result in discarding 10 to 90 per cent of the taps, but this cost is very small compared with the cost entailed by the production of work that is not uniform in diameter and lead.

This, coupled with the inspection of the form of the cutting edges of the taps and dies, constitutes one part of the inspection, and it should be remembered that what is said of the inspection of the taps applies to both the roughing and finishing taps and dies, providing two are used.

If the lead of the roughing tap is not true, the use of a finishing tap may leave a thread that will seem satisfactory in any ordinary gaging method, and yet one of most undependable character.

The proposed scheme of gaging which is presented for discussion is offered with full knowledge that it may make it necessary to discard a large percentage of taps and dies that have been made for this purpose and that it will require a little more care in inspection, but notwithstanding this apparent handicap, it will not, in the writer's judgment, reduce the output of finished product but will tend to increase the dependability that is of paramount importance.

Everyone knows that interchangeability is of greatest value from the production standpoint, yet interchangeability has in some cases been sacrificed to obtain a fit that would be satisfactory according to the sense of feeling; that is, a finger fit or a wrench fit.

It is well known that a screw fit that at first is what is called a wrench fit may become a finger fit after it has been screwed in and out a few times. It is also known that if both screw and nut are of perfect form and true lead, no such great change takes place by merely screwing the two pieces together a number of times.

The system of gages, both internal and external, includes a "go" and a "no go" gage, but these are supplemented by pitch gages. If the total range of tolerance for the thread of the nut is 0.003 in. at the pitch diameter, there should be two or three gages provided for the different pitch diameters coming within the range of tolerance for the nut. The largest of these gages that will enter two or three threads must pass easily through the entire nut.

For long threads, such as found in airplane turnbuckles and the cylinder sleeve of one of the airplane engines, the pitch gages should be made as shown at *D*, *E* and *F* in Fig. 1. Turning out the middle of the gage eliminates some of the obscuring effects due to crooked holes or to particles of grit lodged midway in the fit.

The limit of tolerance of these gages should be made to conform to the special requirements of the work.

It is conceivable that in some kinds of work it may be desirable to give the nut and screw a slight difference in lead so as to equalize the stress of each thread, to compensate for any difference in extension that may exist between the screw and the nut when subject to the working stress.

The "go" and the "no go" diameter gages should be short and of perfect form. The lead gages may be a trifle flat on top of the thread to insure clearance.

James Hartness.

Springfield, Vt.

Accuracy vs. Precision, and the Gage Problem

To the Editor:

A gage is an instrument indicating physical limits, employed in measuring duplicate parts.

Manufacturing tolerances are the established limits of parts which will properly function.

It is obvious that there must be a definite amount of clearance between male and female components. The maximum clearance should be made as large as the nature of the work will permit, and the minimum clearance should be made as small as will permit of the ready assembling of the parts. Thus we will establish the maximum manufacturing tolerances which represent the rejection points. To insure uniformity of manufacture within these established tolerances, gages are made to check the rejection points. Allowances must be made to take care of inaccuracies developed in the construction, and use of, these gages provided to accept or reject the work.

Minimum male and maximum female gages, made to the extreme tolerances, soon become unserviceable by wear, as work which is beyond the established tolerance will be acceptable to such gages.

Maximum male and minimum female gages should be made as near the extreme limits of tolerance as manufacturing conditions will permit, for work passed by these gages after becoming worn will be within the established tolerances.

Extreme refinements in gage manufacture are most expensive, and are unwarranted by the functioning of ammunition components. The variation of gages within the established tolerances (operating to reduce the manufacturing tolerance of the component) is an economic question which concerns only the manufacturer. All gages within the established tolerances of the component which are acceptable to the manufacturer as master, inspection or working gages should be accepted.

These are basic principles controlling the manufacture of interchangeable parts and the standardization of gages therefor.

The gage problem is a simple problem if we leave it so. The details of its operation require constant supervision, but

this supervision is only necessary to insure that we do not leave the straight and narrow path.

Many attempts have been made in the past few years to develop a science of gages that would either automatically run itself, or that would enable inexperienced or untrained persons to control it. The writer has come in contact with several of these attempts, and has observed their rise, decline and fall, each scheme going through very similar successive phases. Schemes developed by novices without experience of actual conditions; elaborate, expensive and inefficient; appearing ideal on paper, but disregarding basic principles; developed as an end in themselves, instead of as a means to an end; finally discarded and the matter handled in the simple and direct manner that governs the other manufacturing tools.

A gage is a manufacturing tool. The purpose of a manufacturing tool is to aid production. A gage should be used as a preventive and not a cure. Gages properly used increase production and reduce scrap. If this result is not obtained there is some basic fault present.

There are two kinds of results in regard to dimensions obtained in manufacturing. For want of better terms, we will entitle them accuracy and precision. These two results are often considered as identical; in fact, if ideal conditions could be maintained they would be identical, but in actual practice these local conditions are seldom, if ever, met with.

In ordinary manufacturing practice, precision only is obtained. Precision is sufficient for a plant which manufactures only its own product. It is only when several separate factories are working independently of each other to produce a common product that a greater degree of accuracy is required.

Let us consider the true meaning of this factor that we are calling "precision." By precision we mean the relative variation that develops between similar parts. For example, we will assume that we have a part to manufacture that contains a hole which we wish to make 0.500 in. in diameter. In the manufacture of these parts we obtain a product in which the difference between the largest and smallest holes does not exceed 0.005 in. in diameter. This would mean that our limit of precision was 0.005 in. for this dimension. The size of the corresponding part which is to assemble into this hole would be developed in relation to the size of the hole obtained, allowing the necessary clearance. It would not matter if the absolute size of these parts was off 0.008 in. or more, as long as the requirements of precision are met. As time goes on, the absolute sizes often fluctuate in actual practice; but as long as the relative precision of the companion parts is maintained and the quantity of production is balanced, the results obtained are satisfactory. Whether or not this is the most economical method in the long run is an open question.

In order to maintain accuracy, all the requirements of precision must be met, and, in addition, all checking and testing instruments and other standards must be compared against a fixed standard. This results in the following situation: If a tolerance of, say, 0.004 in. is given for any dimension, if precision only is required, the whole 0.004 in. is available for a manufacturing tolerance. If accuracy, however, is required, and as it is impossible to make our testing instruments without some degree of error, all errors in our testing facilities are subtracted from the total permissible tolerance, thus actually giving us a smaller manufacturing tolerance. The more nearly accurate our checking facilities are, the greater the per cent of the tolerance remaining for manufacturing variations.

The confusing of these two factors—accuracy and precision—has been the cause of many difficulties and misunderstandings, particularly during the past three years, in the manufacture of munitions. A company would take a contract to manufacture certain articles to specified limits of accuracy. This company had manufactured their own product to similar limits of precision, or assumed that they had, and foresaw but little difficulty in meeting the requirements. But when the actual production started, and they were required to maintain the specified degree of accuracy, they discovered that there were much more severe conditions to be met than they had ever contended with before.

The establishment of manufacturing tolerances is too often based upon assumptions rather than definite records of past performances. For example, some time ago I personally made some tests at a plant covering a period of a couple of months, to determine, among other things, what their normal variation in milling cuts amounted to. This company was an old established concern, produced work of the highest quality, and had a very complete inspection system. The use of limit gages, however, was not general. In many cases only a "go" gage was provided, and all work was required to "fit" this gage. This company assumed that all work which passed this inspection did not have a total variation of over 0.001 in. They were so certain of the fact that they would not have hesitated to give sworn evidence that they could hold their milling cuts within a limit of 0.001 in. But the tabulation of several hundred measurements of the same dimension on similar pieces revealed the fact that their normal variation in milling cuts amounted to over 0.005 in. instead of only 0.001 in. Similar conditions exist in many other plants.

Another striking example in this connection is in regard to threading tools and gages. The producers of these articles will only guarantee their product to a limit of error which seems excessive in comparison with their specifications of a few years ago. As a matter of fact, these tools are practically the same as those made in the past, but the facilities for checking them have been so improved that discrepancies are now discovered which in the past had been assumed to be very much smaller. These examples could be multiplied almost indefinitely.

The answer to this whole problem is to face the facts, and base all plans upon the results of actual tests and investigations rather than upon assumptions. If the conditions are known we can take steps to meet them. As long as they are not known or understood, difficulties will constantly arise—difficulties that result in almost unending delays and extra expenses.

The following is suggested as one of many possible plans that will operate economically, simply and efficiently:

The logical first step toward producing accurate work is to provide physical standards, or master gages, to control the gages. These standards represent the rejection points: all gages within these limits are satisfactory; all gages beyond these rejection points are discarded. The design of these standards is not of great importance, except as it assists in the verification of the inspection and working gages. In the majority of cases a master of the same design and construction as the gage gives very satisfactory service. For profiles, tapers and other similar forms, a male master for a female gage is often the most efficient.

A drawing, properly dimensioned, gives those dimensions which it is essential to maintain. This automatically controls the design of the gage, indicating the points for which gages must be provided. It also thus specifies the holding points for the work, as it is a self-evident truth that the work must be located in relation to the cutting tool from those points on which a gage is applied.

The construction of the gages should be carried out under the same general principles that govern the construction of the tools. If a tool, or gage, tends to wear larger, the policy is to make it as small as is consistent with the manufacturing conditions without going beyond the rejection points. If the tool, or gage, tends to wear smaller, the reverse is true. Extreme refinements in measurement or construction only become necessary as they approach closely to the rejection points.

After the gages are completed and checked against the rejection points they may be graded according to the requirements. We will assume that there is a shop inspection and a final inspection. This would require three groups, one for the machine operators, one for the shop inspection, and one for the final inspection. Those gages which show the greatest amount of variation within the rejection points would be given to the machine operators. Those measuring closest to the rejection points would be used on the final inspection. The intermediate gages would be used for the shop inspection.

An efficient gage inspection is imperative in any case. Under this plan all gages of the same type would be inspected and regraded at the same time, and the proper distribution again made.

All persons who handle the gages should be properly instructed in their use. It should hardly be necessary to say this, but in the past much unnecessary expense has been caused by abuse of gages. The final inspectors should establish the standard method of applying the gages to the product, and all other inspectors should be instructed accordingly.

This plan would entail the minimum gage expense and insure the maximum of service from each gage. This plan includes all types of gages.

Owing to the fact that thread gages involve such a large number of factors, it might be advisable to discuss this subject in some detail.

The main function of all threads in ammunition components is to hold two pieces together, and it is advisable to use standard forms of thread wherever possible, as the various factors of these standard threads are definitely established and extensively tabulated.

A thread is cut with a tool carrying a fixed form, whether this thread is made with a tap or die, chased on a lathe or milled. It is therefore evident that a variation in the diameter of one factor will be accompanied by a corresponding variation in all other diameters cut at the same time with the same tool. Statements have been made to the effect that the pitch diameter was the most essential factor of a thread, and efforts have been made to control that diameter to closer limits than the other diameters, but the statement is fallacious, and the attempts were unsuccessful.

The pitch diameter of a screw is that diameter where the thickness of the thread and space are equal. Its only function is to locate the angular flanks of the thread. If a standard form of thread is employed, this function becomes useless, because a standard form of thread carries with it a definite relation of these flanks with the outside and root diameters. The pitch diameter of the male thread does not coincide with the pitch diameter of the female thread. The essential requirements of the threads used on ammunition components are the angle or flank of the thread in contact, the load and the amount of contact between male and female threads. In most cases the ammunition is so designed that the "set back" due to firing would hold the parts firmly in position without any threads, so that the main consideration on such threads is that they be sufficiently strong to hold the parts together during transportation and handling.

In those cases where the "set back" must be withstood by the thread, one of sufficiently coarse pitch should be used, so as to allow of liberal tolerances and still retain sufficient strength to meet all conditions.

It seems to the writer that instead of profiting by the experience in this work that has been gained by the manufacture of large quantities of similar articles for several of the foreign governments, particularly in regard to threaded parts, and of going on from where that work left off, we are starting almost at the beginning, and have still to solve again many of those problems that were well advanced. For example, on many tapped threads the British inspection consisted of the use of a "go" or minimum plug thread gage, which would insure interchangeability, and a "not go" or maximum plain plug gage which would insure a sufficient area of contact. A visual inspection of the thread would insure that the shape of the thread or width of flats at the root diameter was sufficient to give the required strength, as the factor of safety in regard to its strength was large, and any weak threads that met the requirements of these two gages would be very evident at the visual inspection.

The gage problem is about what we make it ourselves. If we attempt to create an elaborate and exacting system of gages considering the subject as an end in itself, we will but store up for ourselves future trouble and great expense. If we consider it in its true light, as a means to an end, and handle all its many details in the same manner, and following the same general principles that are employed in dealing with the questions in regard to other manufacturing tools, we will find it a simple problem. As was stated before, the whole subject is covered by the first page of this paper.

The Dake Steam Turbine

To the Editor:

I have read with great interest the paper on Commercial Analysis of the Small Steam Turbine Situation, by W. J. A. London, as published in The Journal for December 1917.

I note that in enumerating the various types and makes of steam turbines, the statement is made that the Bliss, Dake and Wilkinson turbines are either no longer on the market or are not seriously competitive. I wish to correct this statement, which may have arisen from the fact that the Dake turbine is no longer manufactured by the Dake American Steam Turbine Company, of Grand Rapids, Mich., this company having gone out of business.

The Dake turbines are now being manufactured by the Pyle-National Company, Chicago, Ill., and there have been built and are in successful operation 22,300 of them, aggregating some 70,000 hp. These turbines are of the single-stage impulse type made under my patents, and substantially all of them are used in connection with turbo-generator units. More than 80 per cent of the electric headlights in operation on steam locomotives today are driven by turbo-generators manufactured under the Dake patents.

Charles W. Dake.

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

THE minutes of the January meeting of the Council, published elsewhere in this number, record the transactions of several items of business which will have an important bearing on the Society's activities during the coming year, and which I am glad to comment upon, particularly in reference to the committee appointments by President Main, which are a controlling factor in the management of the Society.

On the Finance Committee, Theodore Stebbins, consulting engineer of New York City, has been appointed in place of W. H. Marshall, resigned. Mr. Stebbins has previously served on the Membership Committee of the Society, and has specialized of late years in the financial features of engineering undertakings.

Mr. Robert M. Dixon, Chairman of the Finance Committee, whose term of office had just expired, was reappointed. During the past few years the Society has been more fortunate than its members realize in the sound financial administration and progressive business policies its Finance Committee has maintained. Since Mr. Dixon became Chairman of the committee in 1911, the membership of the Society has increased from 4000 to nearly 9000, and the total annual income from \$97,600 to \$207,000. In 1911 the Society owed \$81,000, but had, besides its investment in the Engineering Societies Building, \$20,000 in cash and bonds, and trust funds amounting to \$42,000. At the present time it is owing nothing, has equity in the enlarged Engineering Societies Building, and has cash and bonds amounting to \$130,000, utilized in trust funds and working capital.

During this period the Finance Committee has consistently held to the policy of allowing for the annual budget only 90 per cent of the estimated income, reserving 10 per cent to insure an annual contribution to the reserve fund to guard against contingencies. Its chairman has also advocated and stood back of the effective work of the Increase of Membership Committee whereby the membership of the Society has been more than doubled, and at the same time the average professional standing of membership has been raised. The initiation fees were formerly used to retire the certificates of indebtedness of the land fund, resulting in the cancellation of this indebtedness last July, which must be regarded as a remarkable record. At the present time 50 per cent of the initiation fees are placed in reserve and the balance is available for current expenses.

This brief statement shows the sound financial condition of the Society and the debt which its members owe to the foresight and ability of its Finance Committee and its able chairman, whom Mr. Main has so fortunately prevailed upon to continue on the committee.

Many committees of the Society have lost valued members because of their entering the service of the Government. In the case of the Committee on Meetings, John H. Barr left for that purpose, and J. W. Upp of Schenectady, who took an active part in the interesting session on the Woman Worker at the last Annual Meeting, was appointed in his place. The regular appointee to the Committee is W. G. Starkweather of Boston, Mass., whose work as Secretary of the Boston Section is widely known and appreciated.

While the requirements of the Committee on Meetings are such that frequent meetings must be held, necessitating residence within easy reach of New York, the effort has been made to secure a committee as widely representative as conditions will permit, and its members now come from the cities of Schenectady and Ithaca, New York; Elizabeth, N. J.; Boston, Mass., and one from New York City. Prof. Robt. H. Fernald, of Philadelphia, is the retiring chairman, and the last Annual Meeting and the Spring Meeting at Cincinnati, which came under his direction, have been generally regarded as the most successful and enthusiastic conventions which the Society has held.

On the Publication Committee two new appointments were required because of war conditions. These are George A. Orrok, formerly mechanical engineer for the New York Edison Company, and now consulting engineer with an office in New York, who has for many years been a student of engineering periodicals; and H. H. Esselstyn of Detroit, Mich. In the appointment of Mr. Esselstyn, there is brought to the Publication Committee one who represents the viewpoint of our members of the Middle West, to whom the Society's publications should be of increasing importance, forming as they do the main connecting link between such members and the various sections throughout the country, including New York. Mr. F. R. Low, who has been chairman for the past five years and a member for part of a previous term, because of his intimate acquaintance with publishing and his sound judgment in such matters, has been a most valued member. The regular appointee on the committee is Ralph E. Flanders, who has had publication experience on *Machinery,* and is now general manager of the Jones and Lamson Machine Company, Springfield, Vt.

On the Public Relations Committee the new appointee is J. Waldo Smith, chief engineer of the Board of Water Supply, New York City, who has been identified with important public-works construction for many years.

Of all the committees of the Society, none has more arduous duties nor requires more conscientious effort than the Membership Committee, on which W. S. Timmis is the appointee. The Society has sustained a sad loss in the death of the former chairman of the committee, L. R. Pomeroy, whose place was temporarily filled during part of the past year by James W. Nelson, with Hosea Webster as acting chairman. Mr. Timmis is a consulting engineer in New York and has specialized on printing machinery and the construction and equipment of printing plants. Incidentally he was consultant for the large plant where THE JOURNAL is now printed.

On the Library Committee, John W. Lieb, who retires, has been succeeded by W. N. Best, President of the W. N. Best Company, Inc., New York. This committee has the duty of serving on the Library Board, administering the Joint Libraries of the four Founder Societies. The annual report of the Board appears in this number.

The House Committee, which is responsible for the maintenance of the Society's headquarters and for its homelike surroundings, has as its new appointee J. D. Maguire, President

of the Maguire Rubber Company, of New York. He succeeds Fred. A. Scheffler, who has contributed generously of his time both in connection with the House Committee and in providing for the pleasure of visitors at the annual meeting.

To the Research Committee has been added one of the strongest men in the department of research in the vicinity of New York, Prof. Walter Rautenstrauch of Columbia University, who succeeds Ralph D. Mershon. It is believed by many that the Research Committee affords the greatest opportunity in the Society for useful service, through the coördination and development of research work in colleges and among the industries. At present, the Research Committee has several sub-committees engaged upon important investigations.

Prof. Frederick R. Hutton was reappointed to the Constitution and By-Laws Committee, where his intimate knowledge of the history and precedents of the Society are invaluable. Professor Hutton of this committee and Mr. Dixon of the Finance Committee are the two members of Standing Committees who received reappointments. The President in making appointments tried, so far as is possible, to distribute them among the membership at a distance from headquarters for the obvious reason of bringing members in touch with the Society.

The Standardization Committee acts as a coördinating committee to direct and unify the standardization work conducted by the several special committees of the Society. Two new members were appointed: Prof. L. S. Marks of Harvard University and Massachusetts Institute of Technology, the author and compiler of the Mechanical Engineers' Handbook and at present engaged upon expert work for the Government in connection with engines and carburetors for aeroplanes; and C. F. Hirshfeld of the research department of the Detroit Edison Company.

Of perhaps greater importance than the personnel of our present committees was the preliminary action taken at the Council meeting, at the suggestion of President Main, looking toward the adoption as a fixed policy of the Society of the plan carried out under the administrations of Dr. Jacobus and Dr. Hollis for nominating the Society's officers. This plan is entirely democratic in that the Nominating Committee is made up of representatives from the various sections or groups of sections throughout the country. The Local Sections Committee of the Society has been asked by the Council to formulate rules for incorporating this plan into the Constitution and By-Laws, thus making it a fixed policy to nominate officers through representatives who actually represent the widely distributed membership. This is a policy which has been carried out by the American Society of Civil Engineers.

CALVIN W. RICE, Secretary.

COUNCIL NOTES

A REGULAR meeting of the Council was held in the Engineering Societies Building on January 18, beginning at 11 a. m. and continuing throughout the afternoon. There were present Charles T. Main, *President; Past-Presidents* Ambrose Swasey, D. S. Jacobus, John A. Brashear, W. F. M. Goss, F. R. Hutton; Wm. H. Wiley, *Treasurer;* Robert H. Fernald, D. R. Yarnall, John Hunter, H. de B. Parsons, Fred N. Bushnell, R. M. Dixon, *Chairman Finance Committee;* Calvin W. Rice, *Secretary;* F. R. Low, *Chairman Publication Committee;* and by invitation, Dr. C. R. Mann of the Carnegie Foundation and Mr. E. J. Mehren, Editor of the *Engineering News-Record.*

Committee Appointments: The President announced the following appointments to standing and special committees: *Finance*, Theo. Stebbins, one year, R. M. Dixon, five years (reappointment); *Meetings*, J. W. Upp, one year, W. G. Starkweather, five years; *Publication*, George A. Orrok, one year, H. H. Esselstyn, three years, Ralph E. Flanders, five years; *Public Relations*, J. Waldo Smith; *Membership*, W. S. Timmis; *Library*, W. N. Best; *House*, J. D. Maguire; *Research*, Walter Rautenstrauch; *Constitution and By-Laws*, F. R. Hutton (reappointment); *Standardization*, L. S. Marks, two years, C. F. Hirshfeld, five years; *Sections*, H. B. Sargent.

Nominating Committee. Action was taken toward continuing permanently the custom inaugurated during the presidential terms of Dr. Jacobus and Dr. Hollis of appointing as a nominating committee for officers representatives selected by the various Local Sections, arranged in groups for this purpose. The following resolution was passed:

Voted: That the Sections' Committee as a special committee of the Council, with Mr. Yarnall as chairman, be requested to report to the Council suggestions of procedure whereby the Nominating Committee may be regularly chosen through the nomination by sectional groups of the Society along lines similar to those of the American Society of Civil Engineers, and in accord with the custom of the Society for two years.

Annual Meeting Resolutions. As recorded in THE JOURNAL for January, resolutions were passed at the Annual Meeting and referred to the Council: (1) A resolution at the business meeting providing for a committee to investigate opportunities for coöperation between the Government and the technical schools in the training of men for service in the War and Navy Departments. (2) A resolution introduced by Sir Charles Ross at the Machine Shop Session calling for a board to be intermediary between manufacturers and inspectors, and the Secretaries of War and the Navy, to hear complaints and give advice; (THE JOURNAL, Jan. 1918, p. 67). (3) A resolution adopted at the Gage Meeting asking for the certification of all master and reference gages, and standards of measurements, where so required, by the Bureau of Standards as the official agency for the purpose. (THE JOURNAL, Jan. 1918.)

In respect to these, (1) the Council directed the appointment of a committee; (2) a letter was read from the Secretary of War expressing appreciation of the Society's helpfulness and stating that it was planned to take up at once the suggestion of an intermediary board; (3) the Council approved and referred the resolution back to the Gage Committee to take up with the various Bureaus of the Government, and also asked the Secretary to present it to the Engineering Council.

Standardization of Bolts and Nuts. In response to a request for standardization by Mr. C. B. Auel, it was voted that the Engineering Council be requested to consider the advisability of placing under the Engineering Council all standardization committees of the four societies to deal with standards wherein two or more societies are interested.

Engineering Education. Dr. C. R. Mann, of the Carnegie Foundation, brought to the attention of the Council the proposed plan of the Federal Board of Vocational Education to divert the Engineering Colleges of the country for a period of five months from their regular work of training engineers

to the training of technicians for the war. Resolutions were passed expressing the opinion that such a step was unwise at this time.

Amendment to By-Law 16. Voted to approve the following revision of B16:

B16*a* The Council may in its discretion restore to membership any person dropped from the rolls for non-payment of dues or otherwise upon such terms and conditions as it may at the time deem best for the interests of the Society.

B16*b* The Council may in its discretion remit the dues of any member of the Society in any grade who is engaged in military or other patriotic service of the United States during the continuance of the war conditions and for a period thereafter.

B16*c* The Council shall permanently exempt from dues any member of the Society who has paid dues for thirty-five years or who shall have reached the age of seventy years after having paid dues for thirty years.

Boiler Code Interpretations. The record of Boiler Code Interpretations covering Cases 181 to 184 were approved and ordered published in The Journal. They appear elsewhere in this issue.

Membership Badges. On recommendation of the Membership Committee, a smaller size of badge was approved for those who prefer it to the larger badge now exclusively used.

Members in Military Service. It was voted that members who have honored the Society by entering the military service of the United States shall receive all privileges of their membership and have their current dues remitted upon request.

Printing of Reports. Printing was authorized of the preliminary report of the Committee on Tolerances in Screw Thread Fits; the report of the Committee on Weights and Measures; and three preliminary reports by sub-committees of the Research Committee, covering Flow Meters, Bearing Metals, and Lubrication.

Employment Work. In view of the extensive growth of the employment work of the Society, which has been conducted under the personal supervision of the Secretary, it was voted that this activity now be assigned to a committee for its direction, and it was suggested that the work be combined under the same committee with that of the Engineering Resources Committee, which now is supervising the work of supplying engineers for Government service.

Isherwood Bust. The Council accepted with deep appreciation the gift from Miss Isherwood of a pedestal for the bust of Admiral Benjamin F. Isherwood, which was presented to the Society at its Annual Meeting.

Appointments. The following committee and other appointments were authorized:

Engineering Council. Charles T. Main was appointed a member for one year in place of Arthur M. Greene, Jr., resigned.

Worcester Section. On recommendation of the Sections Committee for officers of the Worcester Section: George I. Rockwood, *Chairman;* H. P. Fairfield, *Secretary;* W. W. Bird, W. H. Damon, George N. Jeppson, F. W. Parks.

Fuel and Fuel Conservation. As a representative on the Advisory Committee on Fuels to the Bureau of Mines, O. P. Hood.

Washington Award. In response to a request from the Western Society of Engineers for representatives to serve on its Board of Washington Award for Engineering Achievement: M. E. Cooley for one year and Charles Whiting Baker for two years.

Junior Prize Committee. A. L. DeLeeuw, *Chairman;* J. A. Brooks and George B. Brand.

Student Prize Committee. George B. Haven, *Chairman;* F. R. Hutton and William Kavanaugh.

Machine Shop Practice Committee. Ralph E. Flanders, *Chairman,* for one year, and George Langen, Henry Spencer and William A. Viall for five years.

Tellers of Election. R. F. Jacobus, *Chairman;* Norman G. Reinicker, Claude Hartford.

Calvin W. Rice, *Secretary.*

THE PRESS ON THE WAR CONVENTION OF THE SOCIETY

AMERICA is just now beginning to mobilize her engineers so that the present world war may be the last great war. And in the light of this mobilization the thirty-eighth Annual Meeting of The American Society of Mechanical Engineers assumes extraordinary interest. Thus the *Iron Trade Review* strikingly characterized the Society's war convention, and it is a matter of gratification to report that the magnificent spirit of patriotism and public service that ran through its many sessions was similarly recognized in every other press notice. The *Engineering News-Record* commented upon the timely addresses that "dealt with the manifold and vital relation of the engineering profession to war-supply requirements." The *Evening Sun* of New York gave full credit to the hundreds of mechanical experts who have been sacrificing their time and money in war work and who quietly and unostentatiously have aligned themselves in a solid phalanx behind the Government.

The above press comments are only reflections of the general attitude that is now being taken toward the engineer. It is becoming more and more evident that in these days of war the engineer must come out of his "technical shell," must become a citizen of the world ready to bear the great economic and social burdens that of necessity will have to be placed upon his shoulders. The troops are fighting valiantly at the front; behind them are the great national executive organizations that direct their movements. But behind both are the engineers—the engineers in all fields—whose thoughts and skill are constantly changing the state of peace and war. Through many of the press reports there runs this undercurrent of thought: the present condition of affairs seems to indicate that the engineers have used their power only to unloosen the great destructive forces that are spreading havoc and misery broadcast. It is for them to vindicate themselves; to allow their power, their skill and the great store of knowledge at their command to run into constructive channels so that the great forces of science will be used for man and not against man, and so that the civilization of the world that has been built up so slowly and so laboriously during the long centuries of man's existence on the earth shall not perish.

The Society is well aware that just at present the need of diverting engineering into more beneficial channels should occupy the minds of all thoughtful and farsighted men, and that the mechanical-engineering field should and must be so broadened as to be able to include the great economic and industrial problems of both today and of the future.

Forbes' Magazine says of the meeting: "Human engineering is but one of the many phases of the mechanical engineer's

broadened field in an age when the direction of industry is more and more passing to the hands of 'masters of material,' represented by the industrial engineer whose business it is to provide both management and workmen with scientific industrial methods and accurate records of production." And in accord with this development of the field of mechanical engineering the Society held its session on Management and invited surgeons, Government officials, Red Cross directors, psychologists, psycopaths, social workers and others to coöperate in putting back upon the payroll of the world both the war cripple and the industrial cripple and thus make of them useful and independent members of the state instead of objects of charity. Not only must the existing labor supply be improved and rehabilitated, but a new supply must be added in such a way that our production and distribution in the future will be allowed to reach the maximum point of efficiency; and thus at another session of the convention the question of the employment of women in the skilled industries was considered from a mechanical as well as a psychological standpoint.

The conservation of time and energy, of food and fuel, is a matter of the most vital importance both at home and abroad. The press had only words of praise for the Society's recognition of this fact and for its inclusion in its keynote session a consideration of the problems of conservation that the Government with the aid of the engineer is attempting to solve today.

There was hardly an account that did not contain at least one extract from Dr. Hollis's address on Universal Service in Peace and War. The assertion of Professor Kimball that "mechanical engineering would soon include every subject in the world and that the aims of the Society ought to be therefore redefined," was another favorite point for press comment.

The fuel situation as outlined by Professor Breckenridge was the subject for much discussion and speculation, and the statistics given by Mr. Myers in his paper on Preventable Waste of Coal in the United States must have touched a vital chord in the fuel question, for they were quoted again and again.

The conservation of energy and time as treated by Mr. Gregg, Mr. Gantt and others, was heartily endorsed by the daily as well as the technical press. Special attention was directed to the fact that not only were the timely subjects of transportation, airplane building, cantonment construction given to the assembled engineers for consideration but for solution as well, and the *Iron Trade Review* predicted that "undoubtedly the convention will show fruitful results in coming months."

As was expected, the valuable contributions along strictly technical lines which ordinarily attract so much attention were relegated to a second place by the war subjects. But this is only corroboration of the fact that the country's needs during the war crisis dominated the whole convention so strongly and so potently, and that so far as the mechanical engineers of the country, as represented in our membership, are concerned, there is from now on only one task.

Junior and Student Prizes

THE rules covering the awards of Junior and Student Prizes for technical papers have been made more comprehensive this year in that a definite standard has been established by which the papers are to be judged. According to this new standard, the prizes will be awarded for the best papers adjudged from the standpoints of originality of matter, applicability (practical or theoretical), value as a contribution to mechanical-engineering literature, logical development of contents, conclusiveness, completeness and conciseness. These specifications, besides furnishing the examining committees with a definite basis upon which to rate the papers submitted, will also serve to assist competitors in the preparation of their manuscripts.

As to suggestions for topics of papers, besides the usual specific technical subjects, of which there are a large variety in every branch of the profession, papers dealing with how the engineer can be of service in these days of war are this year in order. In this latter connection papers might well be written on such topics as the following:

Laboratories for war testing, including munitions; organization for war research with special reference to munitions and fuel; industrial reconstruction plants to meet the needs of war industries; application of management systems to war plants; records of cost of operating war plants; novel methods of training and managing employees in war plants; workmanship requirements; safety devices and measures for men and women workers; new buildings for housing munitions plants; speed of production in munitions plants; maintaining efficiency of machines used in continuous production; specifications covering munitions requirements; certification of munitions gages; standards and interchangeability in munitions parts; machine-shop practice and inspection in wartime; increased terminal facilities in wartime; new responsibilities of the engineer in wartime, etc.

From the technical standpoint a paper might well be devoted to any one of the following subjects: a description of a new mechanical invention or piece of enginering apparatus; an account of some original work in the laboratory, shop or classroom; a description of a novel modification to an existing plant; an explanation of plans or methods of proposed engineering work; a summary of present practice in a given mechanical field or an argument for or against a particular mechanical apparatus, process, construction, etc.

The prizes themselves and the certificates accompanying them are both inducements to Junior Members and to members of Student Branches to enter these annual competitions. Added incentives are the opportunities furnished by the Meetings Committee and the Publication Committee of considering successful papers for presentation at the meetings of the Society and inclusion in its publications.

The rules covering the award of these prizes are given in the Year Book of the Society, the 1918 edition of which is about to be issued. The last date for submitting papers for consideration by the Committee on Awards this year is June 30. Any other information desired by those who intend to compete will be gladly furnished by the Secretary.

Activities of the A.S.C.E. During the Past Twenty-five Years

AT the December 5, 1917, meeting of the American Society of Civil Engineers, Mr. Charles Warren Hunt, secretary, presented a review of the activities of the society during the past twenty-five years. While devoted fundamentally to the work of the organization, Mr. Hunt has served for even longer than the period it covers. The paper contains sections of particular interest to our Society as a Founder Society and as a sister organization with similar objects and aims.

Mr. Hunt thus adequately sums up the functions of a national technical society:

1 To advance engineering knowledge and practice

2 To maintain the dignity and standing of the organization,

and to preserve the high character and professional qualifications of its membership

3 To keep in touch with, and take proper action on, all matters in which the relation of the profession to the public is involved, and to render service to the nation when occasion demands

4 To do whatever is possible for its members individually, and, in general, to return to them an equivalent for the dues paid.

"The latter function necessarily takes the form of providing opportunity for professional discussion, both formal and informal, which, as in the case of this society, more than 80 per cent of the membership is non-resident, must be through publications."

This latter statement by Mr. Hunt applies with equal significance to our own Society, since, like the Civil Engineers, we have a non-resident membership of 80 per cent. One modification could be applied to the statement with justification, however, and that is that 86 per cent of our membership is included in the Local Sections, an activity which has disclosed tremendous possibilities, many of which, due to the good generalship of our present Committee on Local Sections, are about to be realized. This is as it should be, for whether a society's membership is resident or non-resident, all members should have equal benefits from all the activities—meetings, publications, library, etc.

Another significant paragraph of Mr. Hunt's paper is that devoted to war activities. This applies equally to all the societies, and much of the work in this connection which Mr. Hunt describes has been done jointly by all the societies working together. One unique contribution that the Civil Engineers have made, and for which they should be granted full recognition, is the offering of their former headquarters to the United States Food Administration as a central office for its work in New York State. This offer was made unqualifiedly and was gladly accepted by the Board.

Other sections of Mr. Hunt's paper describe the removal of the Society to its new headquarters in the Engineering Societies Building and show plans of the new rooms, describe the tremendous work of transferring their library, which consisted of 89,000 accessions, of which 67,000 were not duplicated in the libraries of the Founder Societies, gives a history of the local sections, meetings, publications, special c mmittees, and other activities of the Society.

To the report is appended a classification of the library of the Civil Engineers, in which work Mr. Hunt has always evinced a keen interest and which he brought up to a remarkable degree of perfection.

SECRETARY OF COOPERATIVE ACTIVITIES

Appointment of Mr. Alfred D. Flinn to the Secretaryship of the Engineering Council, the Engineering Foundation and the United Engineering Society

A MOST significant step is the appointment of Mr. Alfred D. Flinn, Member of the American Society of Civil Engineers, to the secretaryships of the Engineering Council, the Engineering Foundation and the United Engineering Society. Such an appointment indicates that the necessity for concerted action in all matters pertaining to the engineering profession has been fully realized and that the professional solidarity that has long been the goal of engineers of vision is at the point of consummation.

To Mr. Flinn is given a great task—a task ably begun by the Engineering Council through its Committee on Public Affairs, its War Committee of Technical Societies and through its individual members. Mr. Flinn is worthy of the task; his broad executive and organizing experience and his great skill in securing the hearty coöperation of all his coworkers will stand him in good stead in his endeavor to make of the engineering profession a united profession of service to all mankind. A brief sketch of his achievements and attainments follows:

Alfred D. Flinn Underwood & Underwood

Alfred Douglas Flinn

Alfred Douglas Flinn was born in New Berlin, Union County, Pa., August 4, 1869. He was graduated from the Worcester Polytechnic Institute in June 1893 and immediately afterward went to Boston. His first engagement was with the firm of George S. Rice and George E. Evans, consulting engineers, on surveys for the so-called "alley route" for a proposed elevated railway through the heart of Boston, and on surveys for the Muddy River Parkway. In November, 1893, he obtained employment on the Boston Water Works under Dexter Brackett, engineer of the distribution department, and was engaged upon upkeep, operating and construction duties and extensive tests of fire-department apparatus until the spring of 1895, when he entered the engineering office of the Associated Factory Mutual Insurance Companies under John R. Freeman. Here he was engaged for a few months upon hydraulic experiments and factory surveys.

In July, 1895, upon receiving an offer from Dexter Brackett, Mr. Flinn became connected as transitman with the distribution department of the engineering force then being organized by Frederic P. Stearns as chief engineer of the Metropolitan Water Works for the Boston metropolitan district. He had an active part in the creation of this organization and in the surveys, investigations, designs and construction, rising

through various ranks until early in 1900, when he was made principal office assistant in the Boston office, charged with the preparation of contracts and drawings, investigations and miscellaneous office work. This system included the well-known Wachusett dam and the Wachusett and Weston aqueducts, together with large distributing reservoirs, pumping stations and pipe lines in Boston and the surrounding municipalities. During the winters of 1900-01 and 1901-02 Mr. Flinn gave a course of lectures to senior classes of the Lawrence Scientific School, Harvard University, on water supply and sewerage.

In October, 1902, Mr. Flinn was asked to become managing editor of the *Engineering Record* and removed to New York to take up these new duties. Shortly thereafter the *Engineering Record* was purchased by the McGraw Publishing Company and increased in size and scope. In August, 1904, he left the *Engineering Record* to become general engineering inspector of the Croton Aqueduct Commissioners under J. Waldo Smith, Chief Engineer, and remained for a year in that office. During the year he had charge of the completion of designs for the new Croton dam and Jerome Park reservoir, prepared designs and contracts for the Cross River reservoir and began those for the Croton Falls reservoir, all of these works being parts of the Croton water-supply system of New York City.

During the summer of 1905 the Board of Water Supply of the City of New York was created under special legislation and Mr. J. Waldo Smith was engaged as chief engineer. Mr. Flinn became the first member of Mr. Smith's staff and with him had a large share in the creation of the engineering organization which later earned an enviable reputation for its effectiveness, business-like methods and *esprit de corps*. Until August, 1914, Mr. Flinn was department engineer of headquarters department, in charge of civil-service matters, special investigations, designs, preparation of contracts and reports, inspection of materials, and requisitioning of supplies and equipment for this large organization. August 1, 1914, Mr. Flinn became deputy chief engineer and so remained until he assumed the duties of secretary for the United Engineering Society, the Engineering Foundation, and Engineering Council. The Catskill Mountain water system for providing 500 million gallons daily additional supply of water for New York City, including the Catskill aqueduct, the Ashokan and Kensico reservoirs and other important works, are so well known as to require no detailed description in this brief account of Mr. Flinn's professional career.

From an early period in his engineering work Mr. Flinn has been a frequent contributor to engineering literature, on a variety of subjects, and is one of the compilers of the Water-Works Handbook, in the preparation of which Mr. Robert Spurr Weston, of Boston, and Mr. Clinton L. Bogert, of New York, were associated. This book has been adopted by the U. S. Army Engineers.

Members' Pins and Certificates

A slight increase has been made in the prices of pins and certificates supplied to members of the Society. The new schedule of prices is:

Dark blue enamel four-leaf clover official badge, with letters in bright gold, for honorary-members, members, associates and associate-members:

Pin	$4.00
Charm	5.50
Stick-pin	4.00
Button	5.00

Crimson enamel four-leaf clover official badge, with letters in bright gold, for junior members:

Prices same as above.

Membership certificates, all grades, including engrossing $1.50

A small pin, one-quarter of the size of the present pin, can now be obtained, price $3.00, screw back. It will probably be some time before a complete stock of these pins is on hand, but orders will be placed on file and will be filled as early as possible.

AMONG THE LOCAL SECTIONS

A NEW era in the history of the Local Sections was begun at the Local Sections Conference, held on Tuesday, December 4, during the Annual Meeting of the Society. Mr. D. Robert Yarnall, Chairman of the Committee on Sections, presided and a report on the new By-Laws governing Sections was presented by Prof. L. C. Marburg, member of the Local Sections Committee. Delegates representing twenty out of the twenty-one Sections were in attendance—the largest proportion ever present at a general meeting. In addition there were representatives from four branches of the Connecticut Section, as well as visitors from centers of the country interested in the formation of sections.

The conference was divided into two parts; first, a luncheon, at which the Sections delegates had an opportunity to meet informally the members of the Council, and second, a business meeting. The latter was arranged to develop four topics of importance to all the Sections at this time: 1. The new By-Laws and the Sections. 2. Coöperation between Sections and other local societies. 3. How the Sections can secure papers. 4. The Sections and research

The first of these topics was ably presented by Prof. L. C. Marburg, member of the Committee on Local Sections, in the form of a paper which will be given in full in the next issue of The Journal. The other topics were developed in the form of informal discussion, an account of which follows.

DISCUSSION AT THE CONFERENCE

Coöperation Between Sections and Other Societies

Professor Rautenstrauch (Sections Committee): The Committee on Sections has been very much interested in the work of the different Sections in coöperating with the local engineering organizations. We find that the Sections in St. Louis, Milwaukee, Chicago and Detroit, which we visited about a month ago, are working toward a better coöperation on the part of the local engineering organizations with our national Society, and these visits have been sources of inspiration and encouragement to us, and we hope that during the coming year we may have an opportunity to visit other Sections and become acquainted with the work which is going on.

It is almost impossible to maintain a separate and distinct organization in any community without coöperating with the local sections or branches of other national organizations and local engineering organizations that are in the community. Where there is an engineers' club we find that it is inevitably the case that our Local Section, together with other local sections of the other national organizations, group about the engineers' club or engineers' society as a focal point. In Birmingham, where there is no engineers' club, the Alabama Technical Society was formed

and membership in that society is limited to those who are members of the local sections of national organizations. Thus there seems to be a demand for some centralizing element or influence that the different engineering organizations may group about, and it is only through the coöperation of the local societies in this way that I think we can grow both as Sections and as a national organization.

Mr. Engel (Chicago): We have the Western Society of Engineers in Chicago—a general engineering body, composed mainly of civil engineers, with some electrical engineers and mechanical engineers among its membership. They offered us various encouragements to meet with them. At first we had an idea that the mechanical engineers would not gain very much by an affiliation with them. The Sections Committee gave us a different viewpoint, and we are going to meet with them now, and be one with them. We have coöperated with the other engineers in the formation of a Citizens' Unit, and also in the formation of the whole of the First Illinois Regiment of Engineers.

It has been my own conception, as I have viewed the problems in Chicago, which is the second city in America—a city which in some respects is more the center of the country, and more the center of industry than New York—that the close and cordial coöperation of all of the engineering organizations in that city may ultimately bring about the erection of a second engineering headquarters, which, to many of us, would be of more value, perhaps, than the building in New York.

The first step, however, in doing big things is real coöperation between the engineers, and that has been the propaganda that the Committee on Sections has been carrying on. The engineers must combine their purely local questions with a view to promoting the general welfare of the profession as a whole, while at the same time maintaining a certain individuality in order that the technical interests of a particular profession will be taken care of. In this building we have a bringing together of all of the national engineering societies. It is a kind of affiliation, a coöperation which could easily be brought about in Chicago.

Mr. Radcliffe (St. Louis): We have been coöperating with the local sections of the national societies in St. Louis for many years. It came about very largely as the result of an agreement entered into by the local society a number of years ago to the effect that each section of a national society should present not less than two papers each year at a meeting to which members of the other local organizations in St. Louis would be invited. This has helped us to secure good papers, and we have been assured of at least six meetings a year. The organization is called the Associated Engineering Societies of St. Louis.

There is a point that it might be well to emphasize, and that is in making your arrangements for coöperating with the local sections of the various national societies, do not lose your own identity. We have avoided that this year by planning a definite program, with one monthly meeting of the Local Section of the A.S.M.E. from September to May, and we hold that meeting regardless of the two joint meetings which the A.S.M.E. is responsible for as members of the Associated Engineering Societies of St. Louis, which may be given any time of the year.

Mr. Hoexter (Detroit): We have the Detroit Engineering Society, an organization which has about six hundred members. The mechanicals, civils, architects and automotive engineers are particularly strong in the city, and the Detroit Engineering Society has taken it upon itself to provide speakers, representing the various organizations. The individual societies might ordinarily get out as many as twenty-five men to a meeting, which is rather discouraging for a speaker with a national reputation, whereas if the Detroit Engineering Society brings him to the city, we are assured of an audience which fills the hall to capacity.

Professor Fairfield (Worcester): "What has the Section done to coöperate with the profession at large?" In Worcester there are no prominent engineering societies. We are strictly an industrial city, and we have a technical school of some note. We seemed to find that the Boston Section appealed to a considerable number of us, but that as far as the industries went it did not attract them. When the members of the Society began to consider the fact that Worcester was to be given a chance to have the President of this great Society, we began to discuss the question to see if we could not have the A.S.M.E. coöperating with the industries in such a way as to interest those men who are prominent in the industries, largely in machine-tool building and similar industries. We also have a considerable alumni of the Worcester Polytechnic Institute, located in the city and near it, many of them connected with the industries, so that the Worcester Section instead of coöperating with other sections of other societies, undertook to coöperate with the industries and with the Alumni of the Worcester Polytechnic Institute, and to bring the student body also in contact with the A.S.M.E. This is a good form of coöperation to be considered in many of these smaller cities. It can be done well where a city is the central or focusing point of a number of towns.

Mr. Geier (Cincinnati): We have formed in Cincinnati a joint association of electrical and civil engineers called the Engineers' Club. We have meetings once a month and after every meeting we have refreshments, at a series of small tables seating four to six persons. In that way the men present get thoroughly acquainted with each other. We have ten meetings a year, and out of the ten meetings we undoubtedly have eight at which the papers are of such a character as to bring out an attendance of 200 members or more.

Many of the professors of the University of Cincinnati are members of the club and it seems to be an excellent thing to bring these professors into contact with the practical men who are doing the work in the field of industry, and it is having its effect on teaching in the engineering colleges. There are many places in the United States where the same conditions prevail and we ought to make a strong effort to bring into our Society the members of the different engineering colleges and schools. It is very helpful to the practical men of affairs to have the students and the professors at their meetings—it broadens their viewpoint. In Cincinnati we are getting something of that bigger outlook and vision which Mr. Marburg has so well spoken of.

Mr. Klinck (Birmingham): The Alabama Technical Association is a result of coöperation. Membership in the Alabama Technical Association can only be held by men who are members of one of the national organizations which have representatives in the city, the mechanical engineers, electrical engineers, the mining engineers, the chemical engineers and the architects. Where those societies have the ordinary membership, the men in college can come in. We are going to make the Alabama Technical Association stand for something in the state, not only along engineering lines, but as a public-service proposition.

Professor Rautenstrauch: In order to successfully carry out coöperation, there must be some definite objective as the basis upon which coöperation can be made. One can have social coöperation, coöperation in organization, coöperation in the technical papers and technical meetings, etc. Thus each section should definitely find the objective for the year on the basis of which coöperation shall be carried out. Coöperation is a rather fascinating term, but if it is allowed to stand in the air, there will be no particular element about which there can be crystallization of effort. We as engineers are organizers, and it should be a simple problem for each Section to study its local conditions and then go ahead and appoint as committees in charge of the matter those who will be able to bring about the necessary influences to get the work and the objective clearly defined.

How the Sections Can Secure Papers

Professor Richards (Sections Committee): Last July the Chairman of the Committee on Sections addressed a letter to each of the Local Chairmen. Part of the letter reads as follows:

"The Committee on Sections recognizes that the Sections emphasize the national scope of the Society, and through them membership is made of greater value to each individual.

"Next in importance to the work of the Sections is the development of The Journal and Transactions, and the Sections are expected to perform a real service in this essential. As engineers, we know that only through organization and by having certain individuals charged with a definite responsibility can an objective be accomplished.

"In a Society as large as ours, the personal element is largely developed through the point of contact between member and Local Section and it is evident that if the best publication is to be issued, it must be supported by the active interest and work of the Sections. The Journal should contain each year at least *two* technical papers of live interest from each of the Sections. Take for instance the paper by W. P. Barba on Industrial Safety and Principles of Management, presented before the Philadelphia Section, December 1915, which was considered of so much interest that it not only was published in The Journal, but was later selected for presentation at the 1916 Annual Meeting. See the yellow pages in the July 1916 Journal for other examples.

"If these facts were generally known to the individual members of Sections, we believe members would submit more papers to the Society.

"The Committee on Sections therefore suggests as a uniform practice that each Local Section make a special effort this year to contribute technical papers and data, through the establishment of the following organization:

"Appoint a committee of three, particularly qualified, to study the local field, determine what papers and data your Section is best qualified to contribute, solicit the contributions of papers from your local engineers and report to the Committee on Sections. We would call attention to the fact that these papers need not be long. In fact, brief, concise statements of valuable information often are of equal interest and value to longer papers.

"Appoint a committee of two, qualified by broadness of vision to investigate what researches may be most effectively carried out because of the particular engineering work being done in the locality. Men who are particularly fitted to organize and conduct these researches and report the findings to the Committee on Sections should be appointed."

The Committee on Sections felt that it was particularly important to have a Committee on Papers organized in each Section and that the committee be charged with the work of stimulating the members in the preparation of papers of merit. The papers should not be mere verbal discussions, but should be prepared in a somewhat formal way so that they may be discussed formally, and so that they may be presented to the Committee on Meetings as possible material for publication in the TRANSACTIONS, and for presentation at some of the meetings of the national Society.

It has often been stated that we get out of an organization just exactly what we put in it, and that is a thing we must keep constantly before us. We will get out of this Society just exactly what we put into it and one of the things that each of us should feel desirous of putting into it is a contribution, from time to time, of the things we know about and are interested in as engineers and are competent to discuss. It is an unfortunate commentary on this country that there are no technical publications, outside of the journals and transactions of the national engineering societies, which are really engineering periodicals. We have a host of trade papers, but no engineering publications like the London *Engineer*, the *Zeitschrift*, or the *Revue de Mécanique*. Very few of the national engineering periodicals will publish an article which has a differential sign or an integral sign. Outside of a publication such as our JOURNAL, there is no place where real contributions to the literature of engineering are made, except as they are presented in semi-popular form and reflect the immediate engineering of the time. In expressing the Committee's views, I am sure the national Society will agree that it is exceedingly important that the technical information which the members of the Local Sections have should see the light of day.

MR. FRENCH (New York): At the Conference Luncheon this noon, Professor A. M. Greene threw out the suggestion that in years to come the best papers would probably come to the Society for the general meetings through the Sections. As a commentary on that, I would like to call attention to the fact that at the 1917 Annual Meeting we have assigned on the general program, as a result of a review of the Sections papers for the past year made by the Publication Committee, four Sections papers. Last year we had five or six. As a general rule there are about half a dozen Section papers, selected from those published in THE JOURNAL, which are given for discussion at the Annual or Spring Meetings of the Society.

I think that clearly indicates that the bulk of the papers presented before the Sections are either quite local in character, or else, as Professor Richards has just suggested, more popular in character than would be considered as suitable for permanent record in the annual volume of TRANSACTIONS. As a matter of course that would be expected. It is desired to have the Sections' meetings of general interest and treat subjects of local interest, and I doubt very much whether many Sections meetings can be devoted to the highly technical matters that the Society would wish to put on record in the annual volume of TRANSACTIONS.

Nevertheless, I would like to impress upon all of the Sections' representatives that the strength of the publications of the Society must eventually rest with the Sections, and it is very evident why that is so. It cannot be expected that a committee of five members, the majority of whom necessarily live in the East, acting as a Committee on Meetings, can select papers for the Annual and Spring Meetings which will be entirely representative of engineering progress in this country. Engineering is too varied in its characteristics and the country is too large to make it possible for any five men to secure thoroughly representative papers. With twenty-one Sections, such as we have, representative of different parts of the country from coast to coast, and from Canada to Louisiana, we ought to be able to put on record the most important engineering events that are occurring throughout the country. It ought to be possible for the members of any Local Section to so keep in touch with the engineering progress in their vicinity that two or three papers a year could be secured dealing with the important events in their vicinity. For example, from the Pacific slope we would naturally have, as we did this last year, a paper on oil refining, or, as in a previous year, a paper on gold dredging, or, as at another time, a paper by Professor Durand on the hydroelectric developments of the Pacific slope. In New York we would expect, as we have already had, a paper on elevators for tall buildings. From the Northwest we would expect papers on coal handling, and grain handling, such as we have already had, and from New Orleans on the drainage and irrigation work carried on there.

What is desired is to have the backing of some committee for every paper that is published in THE JOURNAL, so that it is known that the paper is of some merit in the judgment of a body of our representative engineers. For example, if in Chicago there should be some engineering developments, some research engineering processes, upon which a paper could be secured which might not be considered very suitable for a joint discussion or a local meeting, but would be worthy of publication in THE JOURNAL and for publication in the TRANSACTIONS afterward, might it not be possible for the Local Committee to secure that paper, present it at a meeting where some other more popular paper was given, presenting it by title, or by giving a very brief abstract of it, and stating that it would appear in THE JOURNAL and call for discussion?

We need about two papers a year from each Section, papers of sterling merit, to keep THE JOURNAL up to the standard required for a representative mechanical-engineering journal in this country, and the problem is to work out some basis on which the Local Sections can get these papers. I believe that through the Sections Committee and the Publication Committee a method could be worked out by which the important engineering developments will come to the Society for permanent record.

A little incident came to my attention yesterday. I was talking to one of our librarians. He mentioned that the searches called for and the other work and investigations done by the library employees were more frequently for members of this Society than for any other society. We know that our members send in a large number of calls to the library for information, and I believe that it is largely due to the fact that in THE JOURNAL we have reviews of important articles in other periodicals. Apparently the effort to make THE JOURNAL representative of engineering progress through those reviews is being appreciated by the membership.

Now, cannot we make it more appreciated by having the Sections get together the material that represents the engineering development going on in the country—the machine-tool industry in Cincinnati, the hydroelectric development work on the Pacific slope, and so on throughout the country, and have the material come in backed by the committee in the particular section where the material is secured, so that when the Publication Committee receives it they know it is good matter and worthy not only to be published in THE JOURNAL, but later to be presented at the Conventions and to appear in the annual volume of TRANSACTIONS.

MR. STARKWEATHER (Boston): The Sections stand for the Society to a large percentage of the members, men who never come to New York, and never see the activities in the Engineering Building, or attend an annual convention. We in Boston are very favorably and fortunately situated, in that we draw from a large membership, and we have a variety of interests. Our Section has appointed a Research Committee and a Papers Committee. We have had three general meetings this season—one on trench warfare, one on aeroplanes, and one on shipbuilding. One of the subjects, The Building of a Modern Plant for Submarine Destroyers, would make a good paper.

MR. WHITE (Milwaukee): We have planned a meeting which we think will result in a paper of general interest, and that is on the question of forgings. We have in Milwaukee the largest forging press west of Pittsburgh. That press at the present time is running night and day, mostly on Government work, varying from guns on down. It is proposed to hold our meeting at the works where the press is located and have addresses by about six of the technical experts who have to do with the forgings. We

propose, for instance, to ask a chemical man to tell us about the billets, about the basic and open-hearth processes. Then we propose to have the superintendent of the forging plant tell us his difficulties in forging—the time of heating, the kind of ingots he wants for certain forges, etc.—and then we propose to make a visit to the forging shop and see the forging press in operation.

After this first meeting we intend to have another meeting with discussions by technical engineers as to the possibility of adapting, for instance, low-carbon forgings, high-carbon forgings, nickel steel, chrome and vanadium, etc., to the different work.

Mr. Prindle (New York): The New York Section has tried an expedient that promises very well. On our announcement postcards we have space for suggestions for papers and we also make a place on the reply postal card for suggestions. This has resulted in a wealth of suggestions which insures getting a paper that is bound to be popular.

Mr. Delany (San Francisco): There seem to be two difficulties at present in securing papers in San Francisco. One is that a great many of the best engineers are away from San Francisco on special work for the Government. Several declined for the reason that they were doing special work that is confidential at the present time. That is a difficulty which is probably met with in other Sections, and in San Francisco we would like to know if there is any way of overcoming it.

Mr. Sargent (New Haven): We recently had a meeting of the Connecticut Section under the auspices of the New Haven Branch at which Professor L. P. Breckenridge gave a paper on the Conservation of the Coal Supply. The paper will be read at the Convention under the title of The Fuel Problem. That is our first contribution. We expect to have two or three others, perhaps more, during the year, and will endeavor to have these of local interest, and technical interest, but in Connecticut—not more perhaps than other places—the mechanical engineer is a member of the manufacturing corporation, and he very soon reaches a point where he is not permitted, perhaps, to be too explicit in the matter he gives out, giving in too much detail something that concerns his particular manufacturing plant, and this is especially true at the present time as the country is at war.

For instance, we have in Waterbury perhaps the largest interests in the manufacture of brass in the country, and it would be rather difficult at the present time to have any of the engineers employed in these various brass mills deliver a paper. We are manufacturing munitions in New Haven and in Bridgeport in large quantities. We are manufacturing in New Haven and in Hartford the Lewis machine gun. It would also be very difficult to get men to give a paper on these subjects.

Mr. Langen (Cincinnati): We have had no trouble in getting papers. We get them nearly all by personal contact, going to see the member and having a talk with him and telling him what is expected. We ask him to make the paper short, and ask him to stand for all of the questions that the members care to ask. If a member has a paper which will take forty-five minutes in its presentation, there will probably be an hour or an hour and a half of discussion. The members ask all sorts of questions and the discussion usually brings out more than the paper.

The Sections and Research

Professor Rautenstrauch: The question of research is very important, because it tends to raise the plane of activity of the Local Sections of the Society. Unless we have some definite objective of this sort, we are very liable to go to a lower level of operation than we would ordinarily go if spurred on by this sort of an incentive.

The difficulty lies very largely in making clear just what sort of thing is required under the head of research. The term generally strikes a little fear in the heart, as usually associated with something rather profound, like the integral sign Professor Richards referred to a while ago. A great deal of research does not consist of that sort of thing at all, but consists of rather systematic and logical arrangement of subject matter which need not necessarily be symbolically or formidably presented.

There are in a great many Sections problems that are peculiar to that Section, and it is an attempt to bring out the particular things that are of interest in that Section that the Committee on Research is being formed. The difficulty in doing this sort of thing is generally in the definition of the problem, and very often a considerable contribution to research is made by simply defining the problem. There is no difficulty in getting men to work on a particular line of investigation if the importance of that line is pointed out. That is what makes the difference between the big physicist and the little physicist. The big physicist can define what sorts of problems are real problems, and the little physicist is a man who fiddles around with something that is perhaps very complicated, but yet at the same time doesn't contribute very much to human progress.

As a suggestion, suppose we take the work in the Milwaukee Section. Mr. White is one of the most eminent engineers we have on the design of water wheels, and he knows that there are certain problems in water-wheel design that will bear investigation, and that we are in need of data or information along particular lines which will promote the use of water-wheel design. Why should there not be, then, a clear definition of the whole field of water-wheel design for the purpose of pointing out wherein there is a lack of certain information.

Again, in the Bridgeport district, where brass work is so prominent, there is the question of the manufacture of brass parts, the question of lubricants for the cutting of brass. In many of these works a very large number of lubricating compounds are used. Let a clear definition of what are the essential characteristics of a lubricating compound be given. Let the men who are interested in that particular thing make a statement of the state of the art, giving a clear definition of what are the things we need to know about in connection with that particular subject, and when that is once defined we will find certain fields on which we have no information. We have a great many young college men who are working in this industry, and we want to attach them to the Society at this critical time in their work and get them interested in the Society. We want to get them to contribute to the Transactions and proceedings of the Society and become real live members. Let us point out to them that there is a problem worthy of their consideration, and by pointing that out and getting them organized so that they can go to work, we will get real information for the Transactions of the Society, and save the number who would ordinarily become driftwood in the organization.

It is that sort of thing we want to accomplish through the Committee on Research.

Professor Richards: At the University of Illinois we had the first engineering experiment station organized in this country, or in the world, perhaps. It has not been long since most mechanical engineers were inclined to shy away when the term "research" was used. We were inclined to look upon the term as one that had no particular concern with actual industrial processes, and was all right for the college fellows who wasted their time upon it. That attitude has changed radically within a very few years. This war, of course, will do more to bring to each of us the realization of the absolute necessity for research than would have been possible in any other way.

One of the principal difficulties in the research field is that research costs money. If in any section of the country, where there is a community of interests such as we find in many of the New England States, due to the growth of a particular industry, that industry realizes there are difficult problems which it needs to know more about, and if the men interested can get together and provide a fund and either employ a man and get him to work or perhaps make use of some of the existing research agencies, and by supporting these agencies in a financial way, getting those competent to study in a scientific way the abstract problems presented, that will be one way of doing it.

In the Engineering Experiment Station at Illinois we have been endeavoring, so far as practicable, to encourage coöperative investigations. By coöperative investigations I mean that we furnish such facilities as we may be possessed of, with the understanding that the coöperating agent will provide the funds for materials and supplies, and also provide the special apparatus which may be required to be designed and built for the particular investigations, and also supply the funds covering the cost of special investigators that may be needed to be employed on a full-time basis. We have at the present time a number of rather important investigations under way. One of the most important, perhaps, came about as a result of a piece of research work which we had already done in the coking of coal. It was found that the by-products of the processes devised were of rather unusual character. An American creosote company was given a sample of the by-products, which we had discovered was exceedingly rich in creosote, and in view of the fact that the war had cut off the supply of creosote, most of which came from Germany, they became very much interested in the process. The president of the

company has already supplied us with a fund of $10,000 for the work, and is ready to supply as much more, to carry out on a larger scale the investigations originally carried out on a more or less limited scale.

Since we are a state institution, supported by the people of the state, every coöperative arrangement of this sort is made with the understanding that the results of such investigations belong to the University of Illinois and are available to all of the people of the state.

In a great many of the states during recent years these engineering experiment stations, similar to the one that was organized at Urbana some fifteen or sixteen years ago, have been organized, but most of them are merely for the purpose of doing what we call commercial testing, as distinguished from real research, and yet it is quite possible that in the long run these agencies could be used to coöperate with the industries in that particular section, remembering in all cases that engineering research is tremendously expensive; that one can not guarantee results, and that the investigation may need to be continued for years before satisfactory and valuable results can be secured.

Mr. Geier (Cincinnati): There is no doubt considerable wasted effort now on the part of manufacturers in the same line of business trying to duplicate various laboratory tests and researches. Every concern is doing some research work and it is a waste of money for two concerns to be doing practically the same work, and duplicating the results of each other. I have been suggesting to some of the manufacturers in Cincinnati the possibility of their having an entirely private research laboratory, owned and controlled by a group of manufacturers, or possibly making it more public by attaching it to the university, and having the work done under the direction of the university authorities. No steps have been taken that are definite, but the matter is becoming more urgent as industry finds it necessary because of some of the changes in industrial conditions.

Many heads of manufacturing concerns, who are concerned primarily with the commercial side of the proposition, do not have a realization or appreciation of just how much good a research laboratory on proper lines would be to them from a financial standpoint. I believe if the Society would make an appeal, not only to its membership, but to the managements of industry throughout the country, and place before them in a very practical and persistent manner the need of the country, and the need of the individual manufacturers throughout the country, for a movement of this sort, it would be most helpful. People are listening much more carefully than they used to to suggestions of this sort. Now is the opportune time to make such suggestion, and an appeal should be made either by the committee or the incoming president to industrial managers generally to take a broad viewpoint of the matter, and see if they cannot organize in each community a real research laboratory.

Mr. Wallace (Indianapolis): If the war has taught any one a lesson it has certainly taught the wide-awake manager or manufacturer that research of the right sort on the right basis is of inestimable value. There is a great deal of research work that can be done along manufacturing lines that would not necessarily entail a great deal of expense. For instance, the question of labor is one of the greatest questions confronting the American manufacturer today, and with regard to the question of labor in this country, the subject has not been touched. We as a manufacturing organization went after that question and worked out a very comprehensive program for reducing the labor turnover in our company. We are getting results and during the last three months our labor-turnover percentage is going down in spite of the fact that the acute shortage of labor has tended to increase the difficulties of the labor situation, and especially the labor turnover.

Again, the manufacturers in a given locality, under the direction of the Local Section in that locality, could perhaps get together and work out problems of research investigation and analyze the causes for scrapping lots of material. In our factory we put that campaign on a patriotic basis. We said to our people at one of our factory meetings, that saving material is a national duty, and we want that as a slogan. If all the local sections in a given locality would get together and concentrate on that question, we would get results which would be of value to everyone.

Mr. Hamilton (Ontario): In Toronto, we are just getting started on the mechanical side of the research problem. The Manufacturers' Association and the government have been financing the matter, but up to now it has been more in connection with the chemical industries. I got notice the other day that the Research Committee of the Manufacturers' Association was ready to take up the research work in coöperation with the mechanical engineers, and especially with the users of iron and steel in the district. In the course of the next few weeks we will form some sort of a joint organization between the bodies that are interested in that problem, the local mechanical engineers and the Manufacturers' Association, and promulgate the problems of the mechanical engineers.

At the close of the meeting Professor Richards gave a timely example of how the Sections could render practical service—he urged the Sections to enter into the national movement for the conservation of fuel. The knowledge at their command would enable them to give practical and special information in their communities regarding the proper use of fuel in heating the homes and the importance of putting the boiler plants in good condition and operating them more effectively, and to bring home to everyone that conservation is a problem everyone has to face squarely.

SECTION MEETINGS

BALTIMORE

December 19. At the second meeting of the Section, Wm. W. Varney, Chairman, reported on the Annual Meeting of the Society and appealed to the members of the Section for papers bearing on the local industrial interests of Baltimore.

The Secretary, A. G. Christie, discussed the fuel situation, and outlined the efforts that are being made to educate the firemen and increase boiler efficiency. He called attention to a Baltimore conference of operating engineers and a proposed assembly of firemen, urging the hearty support of members of the Section.

Dr. D. J. MacAdams, Jr., of the Engineering Experiment Station, U. S. Naval Academy, Annapolis, presented a paper on Microstructure and the Physical Properties of Metals, in which he described the methods followed in preparing a section for metallographic inspection under the microscope. Solutions of metals were discussed and illustrated by slides. Eutectics were treated and sections of tin-lead and copper-zinc compounds shown and the effect of heat treatment was illustrated by slides. Some interesting information was developed with regard to the steels of indicator springs, tool steels and the processes of tempering.

The second paper of the evening, entitled Some Mechanical Problems of the Fertilizer Industry, was presented by Samuel P. Whiteside, Mem.Am.Soc.M.E. He said that the mechanical engineer finds that in special chemical apparatus many mechanical refinements have been overlooked. Widely used machines when applied to fertilizer factories usually develop weaknesses. For example, grab-bucket service transforms a bridge crane from a tool of occasional convenience into a steady worker, but in this new service the machine needs some training and development before it will pass the endurance test.

January 10. A meeting under the joint auspices of the Engineers' Club, the various stationary engineers' associations and the Baltimore Section, was held for the purpose of interesting the firemen of the city in the subject of fuel saving.

Mr. Charles H. Bromley, Associate Editor of *Power*, gave an address on How to Get the Most Out of Coal. A fuller account of the meeting will be published in a later issue of The Journal.

A. G. Christie,
Section Secretary.

BIRMINGHAM

December 20. The subject of conservation of fuel was discussed by F. G. Cutler, Mem.Am.Soc.M.E., and J. W. Moore, Assoc-Mem.Am.Soc.M.E., and it was believed well to formulate plans at some future date with the idea of establishing some fixed methods of procedure in the matter of coal conservation.

A letter was read from the American Uniform Boiler Law Society urging the Local Section to take steps toward securing a boiler law for the state of Alabama, and the following were appointed to investigate the advisability of having a law passed in Alabama adapting a uniform boiler code: F. G. Cutler, Chairman, H. C. Ryding and C. B. Davis.

A short talk on the Handling of the Sick and Wounded in

Actual Warfare was given by H. B. Hess, United States Medical Corps.

A talk on The Use of Graphite as a Boiler Scale Preventative was given by Samuel Stewart, Mem.Am.Soc.M.E., who related experiences at the Thomas Plant of the Republic Iron and Steel Company. Mr. Stewart brought out that after using graphite as a boiler solution, he found quite a saving of coal was accomplished, even though an increased load was put on the plant; it was absolutely necessary that the graphite be kept in suspension and the way this was accomplished was to insert an air pipe in the bottom of the tank containing the water with graphite in the solution. The graphite was kept in suspension by pumping air into this pipe, the air coming either from blowing engines or compressors. Amorphous graphite was much more satisfactory than flake graphite, and cost between 7 and 8 cents a pound; using about 0.005 lb. per horsepower per day, the entire cost of cleaning 9,000 hp. in boilers was about $14.00 per day. The best place to treat boiler feedwater was outside to keep scale from forming, but practically all boiler feedwater constituted a separate problem in itself and what was found to be good in one case would not do in another. The secret of the success of graphite was to keep it in suspension, the idea being that the small particles of graphite would combine with the small particles of scale and make them easy to remove. Graphite could not be expected to be of any benefit if the water contained acids.

At the conclusion of the meeting C. B. Davis, K. Lanrebe, Paul Wright and O. C. Thurlow were appointed a Committee to prepare a program on the conservation of fuel, in coöperation with the Alabama Technical Society.

W. L. Roueche,
Section Secretary.

BOSTON

January 22. An informal reception was tendered to the President of the Society, Mr. Charles T. Main, at the Engineers' club. Among the several addresses given was one by Mr. Balch of the Boston *Transcript* on Europe after the War. A full account of this meeting will be given later.

W. G. Starkweather,
Section Secretary.

BUFFALO

December 12. At the General Meeting of the Engineering Society of Buffalo, W. Fostergen, Manager of the Independent Bureau of Philadelphia, gave an address on Industrial Housing in which he described the work being done by large corporations in this country in furnishing proper housing for employees. Special stress was laid on the point that it is more advisable to make homes sanitary and agreeable than it is to go into great detail regarding conveniences.

December 19. Mr. H. O. Hem. Mem.Am.Soc.M.E., gave a paper before the society on The Evolution of the Scale, in which he brought out the advancement in technical development of the modern scale as compared with the crude methods of early scale manufacturers.

January 9. At the fourth general society meeting L. C. Lowenstein, Mem.Am.Soc.M.E., gave a paper on The Widening Field of the Steam Turbine as a Prime Mover, in which he called attention to the advancement made in steam-turbine work and its widening application, not only as a prime mover for generators, but also for marine propulsion and centrifugal compressors such as blast-furnace blowers.

Other meetings of the societies affiliated with the Engineering Society of Buffalo held during the month included the following:

January 16. The American Electrochemical Society Section held a meeting at which a paper on Electric Steel Castings was presented by Mr. R. F. Flintermann of the Michigan Steel Castings Company, of Detroit.

January 23. At a special meeting of the National Founders' Association moving pictures illustrating modern foundry practice were exhibited. They emphasized the rapid strides made by the more modern foundries throughout the country in the use of molding machines and other labor-saving devices.

January 30. A meeting of the American Chemical Society was held.

F. B. Hubbard,
Section Secretary.

CONNECTICUT SECTION

Meriden Branch

December 21. Chairman C. K. Decherd presented a detailed report of the Annual Meeting of the Society, in which he stated that the work of the Engineer in the War was the keynote of the entire meeting. Introducing the subject of the evening, research work, he said that research may be an endeavor to find something new for the benefit of the world, or information now lacking which is needed, or it may be an effort to make things we now have more efficient and resultant in greater good for all.

Ten-minute papers were then read by J. L. Hutchinson and Charles N. Flagg, pointing out the need for accurate data in engineering organizations and declaring that much of the data now available is either obsolete or inaccurate. In Mr. Hutchinson's paper he stated that the subjects selected for his talk were common ones and universally used. It very often is the case that data available have been worked out to prove some specific problem but when an endeavor is made to use these data on a different problem variables are found which make them practically valueless until they have been supplemented with more details.

Mr. Flagg stated that the work of the heating engineer has never been, and probably never will be, reduced to an exact science. The general practice has been to acquire as much data as possible from whatever source it may be obtained, absorb as much theory as possible, and then when a problem presents itself the task has been to fit the theory to the job, modifying it by the actual experience of the designer.

Charles N. Flagg,
Section Secretary.

DETROIT

January 25. At a joint meeting of the Section with the Detroit Engineering Society a three-part paper on the Complete Description and Test of a Modern Lake Steamer was presented. The topics included: Part I, Description of the Hull, by H. W. Miller; Part II, Description of the Machinery, by Geo. B. Turnbull, Assoc-Mem.Am.Soc.M.E., and Part III, Tests, by A. G. Mattison, Mem.Am.Soc.M.E.

S. J. Hoexter,
Section Secretary.

ERIE

December 14. At a meeting held jointly with the Engineers' Society of Northwestern Pennsylvania and the Erie Board of Commerce, a large and enthusiastic audience representing the various organizations listened with interest to an address made by Prof. Dexter S. Kimball, Mem.Am.Soc.M.E., on Industrial Management.

M. W. Sherwood,
Section Vice-Chairman.

INDIANAPOLIS

January 25. In accordance with a precedent started last year the Section held a joint meeting with the Indiana Engineering Society and the local section of the A. I. E. E. on the occasion of the annual meeting of the former society. Each organization furnished a well-known speaker, Mr. A. S. Harrell representing the A.S.M.E. Section. A detailed report of the meeting will be published in a later issue.

L. W. Wallace,
For the Secretary.

MINNESOTA

December 7. At the joint meeting of the Section with the A. I. E. E., and several other technical societies, L. D. Wildman of the Central Department, U. S. Signal Corps, delivered a lecture on the subject of War Time Work of the U. S. Signal Corps in Aviation and Electrical Communication. A most interesting account of the various branches of the service was given, including considerable detail with regard to the equipment, training and practice pertaining to each branch.

E. A. Wilhelm,
Section Secretary.

NEW YORK

January 8. The chairman of the meeting called attention to the loss of three members of the Executive Committee of the New York Section due to their participation in war activities. After discussion the following motion was unanimously adopted:

> Resolved: That the two remaining members of the New York Section Committee be instructed to appoint three members to fill the vacancies in that committee for the unexpired terms of the resigned members, such appointments to be subject to the approval of the general Sections Committee and the Council of the Society.

The Committee on Local Sections were the guests of the evening, with the following members of the committee present: D. Robert Yarnall, chairman; L. C. Marburg, Walter Rautenstrauch, H. B. Sargent. Mr. Yarnall outlined the ambitions of the committee with regard to the development of the Section activities, after which Professor Rautenstrauch presented an excellent paper on The Relation of Manufacturing to Banking and Research. Professor Rautenstrauch described the development of these relations as advanced by the Industrial Service Department of the National City Bank of New York, and the members present were much impressed by the potential growth of this relation between the engineers and banks of the country. Mr. E. A. Baker of the National City Bank was present and discussed the paper, as did Messrs. H. B. Sargent, George K. Parsons, W. H. Greul, and others.

Previous to the meeting a buffet supper was served which was thoroughly enjoyed by those who attended. The opinion was generally expressed that if the majority of members in the New York Section were cognizant of the opportunities these pre-meeting dinners afforded for acquaintanceship they would be very generally attended. Members not particularly interested in the paper of the evening would find it profitable to be present at the dinner. In future those who attend the meetings will be asked to register and records will be kept so that at the end of the year those who have participated in the meetings will be known.

The Executive Committee of the Section wishes to extend a cordial invitation to all members to attend its meetings whenever in the city. The committee is especially desirous of having out-of-town members participate in the "get-acquainted" supper held in the Engineering Societies Building at six o'clock on the meeting night. Meetings in New York are usually held on the second Tuesday. An exception to this rule will be made in February, owing to Lincoln's Birthday.

W. Herman Greul,
Section Secretary.

PHILADELPHIA

January 22. Prof. William L. Cathcart, Mem.Am.Soc.M.E., and retired from the U. S. Navy, gave an illustrated lecture on The War on Land and Sea. Through the courtesy of the British Pictorial Service, Professor Cathcart showed thirty official views of the recent fighting in Flanders and other places on the front.

On the invitation of the Section, members of the Illuminating Engineering Society attended the meeting.

John P. Mudd,
Section Secretary.

PROVIDENCE

January 15. The Development of the Submarine was the title of the paper presented by Albert Cook Church, one of the best-informed men on this subject in the country. Mr. Church is a consulting engineer and has done work for all the allied governments during the present war and his knowledge both of their types and of German types is very extensive. The lecture was illustrated by a number of slides showing the capture, salving and repair of the German mine-laying submarine UC-5; the developments of the submarine from the earlier types to the present-day super-submarines of enormous tonnage, including plans, interiors with all the maze of intricate machinery, and torpedoes, showing their actual use in warfare; and the attack and sinking of steamers, battleships and submarines. The mechanical principles involved in the design and operation were carefully explained in detail.

In addition to this general meeting several Section meetings were held during January, which included:

January 8. The Machine Shop Section meeting, at which a paper on Gages and Their Use in Quantity Production of Rifles and Munitions was given by T. Frederick McClosky.

January 9. Under the auspices of the Power Section, Mr. Frederick B. Kenney, of the Blackstone Valley Gas & Electric Company, gave a paper on Central Station vs. Isolated Plant.

January 11. The Efficiency Section held a meeting at which a paper on Some Aspects of Scientific Management was given by Albert E. Thornley, of the Narragansett Machine Company.

James A. Hall,
Correspondent.

ST. LOUIS

November 23. A report of the new Research Committee of the Section was read by Mr. Liebee, emphasizing the fact that efforts were being made to interest the manufacturers of St. Louis in the work of this committee. The speaker of the evening was Prof. C. S. Boucher, of Washington University, whose timely address on American, English and French Relations, Past and Present, was of great interest to those present. The meeting was held at the new Statler Hotel, and permission was granted by the management to those present to make an inspection of the mechanical equipment of the hotel.

December 19. At the joint meeting of the Section with the Associated Engineering Societies of St. Louis, George B. Evans, Mem.Am.Soc.M.E., presented an interesting paper on Power-Plant Installation by By-Product Coke-Oven Plants, in which he referred particularly to the power plant recently constructed in connection with the by-product coke-oven installation of the Laclede Gas Light Company at Carondelet, St. Louis. While this plant is of comparatively small size it has been laid out and constructed with all of the care and regard for best engineering practice in connection with the construction of a modern central station plant.

Opportunity was taken at this time of bringing before the Associated Engineering Societies and the Engineers' Club the matter of establishing a research laboratory in the district of St. Louis. Mr. H. R. Setz, Chairman of the Research Committee, solicited the support of all the engineering societies in the St. Louis district.

January 16. A joint meeting of the Section with the Associated Engineering Societies of St. Louis was held at the Engineers' Club under the auspices of the A.S.M.E. Section. Mr. Paul Diserens, Mem.Am.Soc.M.E., presented a paper on The Recovery of Gasoline from Casing-Head and Natural Gas.

R. L. Radcliffe,
Section Chairman.

Student Branch Meetings

POLYTECHNIC INSTITUTE OF BROOKLYN

December 1. Mr. Wunch and Mr. Fialkoff were elected at this meeting of the Branch, to serve on *The Engineer* board as representatives of the Mechanical Engineering Society. Means were discussed for increasing the attendance at the meetings, as the war has caused the loss of many members active in the affairs of the Branch, including Prof. Wm. D. Ennis. After the regular business a paper was presented by Mr. McAustin on Lubrication. Mr. McAustin told of the many problems which had to be solved in this field, especially that of the aeroplane motor. The speaker said that the lack of the proper lubrication hinders the progress of the advancement of this type of motor.

The Polytechnic Institute of Brooklyn has been very active in its coöperation with the Government in the war. Patriotic committees have been organized on smokes, correspondence, comforts, speakers, etc., whose various duties are to supply the Polytechnic men in service with comforts and keep them in touch with the Polytechnic affairs. A company of students has been organized by Professor Chittenden, and has been mustered in the 23rd Regiment; it drills at the armory every Friday.

Besides the patriotic topics given by prominent speakers at the chapel service, courses are being given at the Institute relating to military work, and which include military surveying and naval architecture. By hard and conscientious study, Polytechnic Institute is doing its bit in preparing for the huge rebuilding after the war.

Nathan N. Wolpert,
Branch Secretary.

PURDUE UNIVERSITY

November 20. Good Carburation was the paper presented at this meeting of the Branch, by Prof. O. C. Berry, of the Gas Engineering Department. Professor Berry discussed very clearly the vital principles that are necessary for good carburation, and backed each statement by actual results taken from tests, which had been tried out in the university laboratory. Many different kinds and types of carburetors, taken from an engineering standpoint, were explained and their good and bad features discussed. The different adjustments of the different carburetors were also explained and discussed and the inability of each to meet the ideal requirements. Professor Berry outlined the requirements for an ideal carburetor and the conditions they should be designed to meet under average service.

A talk was given at the December 4 meeting on the Manufacture of Munitions and Aeroplane Parts by O. W. Kastens, a senior in the School of Mechanical Engineering, on his past summer experiences. The different methods in the manufacture of munitions, and especially the methods used in making the detonators, were described very clearly, so far as the speaker was at liberty to do so. Because of the nature of the subject only very general ideas and methods could be openly discussed. The standardization and interchangeability of aeroplane parts was discussed very clearly, and a very good idea was given on what is being done towards helping the Allies with the construction of aeroplanes.

Purdue University has been very active in its coöperation with the Government in the present crisis. Approximately out of the two thousand students in the university last year, only sixteen hundred have returned this year, and many are leaving daily for service in different sections of the army and navy. Many have attended the different training camps and received commissions, while others are enlisting in the signal corps, the artillery and especially in the aviation section. About thirty professors have gone either directly into the army, into the training camps or have enlisted in the ordnance department. Purdue has shown her mettle also by raising $10,000, which was her assessed share of the Y. M. C. A. Fund, and $2000 for an ambulance equipment for the Purdue Ambulance Corps; and, in addition, she has passed the required mark of the Y. M. C. A. Fund by nearly $7000. A movement is now under way in which the juniors, and especially the seniors in engineering, may enlist in some form of service and be allowed to complete their studies, and then go directly into army service.

Claude Kegerreis,
Branch Secretary.

RENSSELAER POLYTECHNIC INSTITUTE

November 7. T. H. Thorn gave a lecture on experimental turbines at the fourth meeting of the Branch for the season. Mr. Thorn confined his talk chiefly to an experimental turbine built by the Westinghouse Company. He detailed the construction and arrangement of the turbine, gave the speed and power developed, and described particularly one that failed under test, delineating the causes of the failure as shown by the machine afterwards. The speaker explained the conditions leading up to the break and gave a few interesting facts concerning the result of the explosion.

S. F. Jeter, Mem.Am.Soc.M.E., followed with an instructive talk upon the strength of riveted joints. Mr. Jeter's talk took the form of an analysis of the boiler seam, characteristics generally overlooked, plate thickness, spacing and pitching rivets, and quick, easy methods of determining the important features of a joint from given data. The speaker illustrated the joint by slides, showing charts adaptable for finding all the necessary data concerning a joint when certain dimensions have been given.

The Institute has been very active in its coöperation with the Government at the present great crisis. There is a long list of Rensselaer men in service, many holding commissions in engineering regiments now in France. Out of the classes of 1918, 1919, 1920 and 1921, 102 men have left school to enter the service. Of the non-graduates 83 have entered the service, and 216 of the graduates are on the Roll of Honor. Aside from this total there are 16 men engaged in the civilian part of the war work. This means a grand total of 417 men on the Roll of Honor. There is an optional course of military drilling offered by the school, and the present two companies formed have a record of one hundred and sixty men.

A "smoke" fund has also been created, and this is serving a double purpose. Each man is expected to contribute ten cents or more if he wishes. Six $100 Liberty Bonds of the last issue have been set aside, and as often as the fund permits, one of them is paid for and turned over to the Troy *Record* to be used in their large Smoke Fund. The Library fund which has recently been adopted has been very successful in its purpose of supplying reading matter for the soldiers in camp. As Dr. Wier, of the American Library Association's Committee, said: "The books thus made accessible to the soldiers and sailors have a double purpose—first, they provide wholesome entertainment to the men; and second, they constantly keep before them the high ideals for which they are fighting."

December 20. At the fifth regular meeting of the Branch R. P. Kolb reported his visit to the Conference of Student Branches held at the Annual Meeting.

A paper on the Spiers Falls Power House, covering the layout and size of the plant, and diagram of the wiring, was given by C. A. Jacobson.

Due to the fact that Mr. Morretti was called into government service, G. H. Carragan was elected his successor as Vice-Chairman of the Branch.

R. A. Marriott,
Branch Secretary.

STEVENS INSTITUTE OF TECHNOLOGY

The president of the Stevens Engineering Society having been called into government service, new officers were elected at the opening of college, as follows: Raymond Mileham, president, and Paul Hiller, vice-president.

A petition was submitted by the Seniors to the Trustees of the College asking permission to eliminate holiday periods and do extra period work in order to finish the college course. The petition was granted and the Senior Class will receive regular college degrees, but will graduate earlier.

December 13. The second meeting was called for the purpose of electing a successor to G. Crosby Hiss, treasurer, who had enlisted in the U. S. Naval Reserve. Mr. Lincoln B. Aquadro was elected to carry on his work.

January 14. Mr. Paul Hiller gave a talk on the new steam automobile shown at the recent Automobile Show, and R. Mileham spoke on Automobile Differentials.

The Inspection Trip Committee reported difficulty in arranging for the regular Wednesday afternoon inspection trips to plants of interest in New Jersey due to the order of the Fuel Administrator closing the plants on that day. A trip to New York later in the year was suggested.

A committee of three was appointed to prepare a new Constitution.

Lincoln V. Aquadro,
Branch Secretary.

THROOP COLLEGE OF TECHNOLOGY

The following officers were elected to carry on the Branch work: Ralph T. Taylor, chairman, Clarence N. Ward, vice-chairman, and Retla Alter, secretary-treasurer.

The College has lost many of its faculty members and professors due to the war, and now has seven representatives on the Council of National Defense, three of whom are faculty members and four are trustees.

In the Mechanical Engineering Department most of the upperclassmen have enlisted and the majority are now lieutenants. To stop this depletion in numbers of the upper classes and to help the Government in every way possible, it was decided to graduate the Senior class on April 6 and the Junior class on September 15. The course for the Juniors will therefore be shortened, but they will be required to work through the entire summer. A course in shipbuilding similar to the one given at Lehigh University will be a required subject for the Juniors and Seniors. In this way it is hoped that a number of students after graduating will enter the shipyards to help in the construction of ships. Others will receive commissions in various branches of the service.

Throop has had compulsory military training since September 1916 under the direct supervision of a captain in the Army (always a West Point graduate) detailed by the Government and the students are consequently now fully qualified for active service.

Retla Alter,
Branch Secretary.

EIGHTH ROLL OF HONOR

ONE HUNDRED AND TWENTY-ONE additional names of members of The American Society of Mechanical Engineers who are now in the Service. This eighth list brings the total number of stars on the service flag to over 700.

ALLEN, THOMAS H., Captain, 306th Engineers, Camp Jackson, Columbia, S. C.

ANDERSON, ARRID R., Corporal, Battery F, 324th Regiment, Field Artillery, Camp Sherman, Ohio.

ASHMUN, LOUIS H., First Lieutenant Engineers, War Department, Trench Warfare Branch, United States Reserve.

BACON, JOHN LORD, Captain, Engineer Officers' Reserve Corps.

BARNUM, CHARLES L., Lieutenant, United States Naval Reserve Force.

BARRON, CHARLES R., Second Lieutenant, Officers' Reserve Corps.

BATTEN, LORING W., JR., Ensign, United States Naval Reserve Force, U. S. S. *Wyoming*.

BAYLR, GEORGE H., First Lieutenant, Ordnance Reserve Corps.

BERLINER, RICHARD W., Captain, 306th Engineers, United States Reserve.

BIXBY, WINFRED H., First Regiment Illinois Engineers, National Guard.

BLISS, EDWIN C., Lieutenant, United States Naval Reserve Force.

BOLGIANO, J. R., Second Lieutenant, Officers' Reserve Corps, Production Section, Carriage Division, Ordnance Department.

BRADY, LABAN J., Second Lieutenant, Company C, 5th U. S. Regular Engineers, Camp Skurry, Corpus Christi, Tex.

BROWN, JOHN WILSON, JR., Major Engineers, United States Reserve, Camp Lee, Petersburg, Va.

BUCKINGHAM, EARLE, Captain, Ordnance Department, Inspection Section, Gun Division, United States Reserve.

BURLING, HERBERT S., Second Lieutenant, Field Artillery, Officers' Reserve Corps.

BURROUGHS, J. H., Captain, Coast Artillery Reserve Corps, Acting Quartermaster, Coast Defenses of the Delaware.

CARSON, C. B., First Lieutenant, Officers' Reserve Corps, Carriage Division, Production Section.

CHEW, JOHN J., Ensign, United States Naval Reserve Force, Bureau of Ordnance, Navy Department, Washington, D. C.

COLE, CYRUS L., Captain, Ordnance Section, Officers' Reserve Corps.

COLVIN, JAMES A., Company E, 313th Engineers, Camp Dodge, Iowa.

COOPER, HOWARD, Signal Corps, Equipment Division, Specification Section.

CRANE, E. C., Second Lieutenant, Engineer Officers' Reserve Corps.

DICKEY, RALPH L., Lieutenant, Ordnance Department, Washington, D. C.

DIEMER, HUGO, Major, Ordnance, United States Reserve.

DODGE, ALBERT, Captain, 316th Infantry, Commanding Company J, United States Army.

DODGE, PARKER V. P., First Lieutenant, Ordnance Department, Washington, D. C.

EBEN, LEON A., Lieutenant, United States Army.

EDWARDS, H. H., Chief Machinist's Mate, Third Naval District, United States Naval Reserve Force.

FARNHAM, G. W., Second Lieutenant, Officers' Reserve Corps, United States Army, Fort Totten, L. I.

FOSTER, CHARLES C., 302nd Engineers, Company C, Camp Upton, L. I.

GFROERER, HERBERT, Second Lieutenant, Ordnance Department, Machine Gun Section, Carriage Division.

GILLAM, W. H., JR., First Lieutenant, Ordnance Department, Supply Division, United States Reserve.

GOING, CHARLES BUXTON, Major, Ordnance Officers' Reserve Corps, United States Army.

GUTHRIE, JAMES, Major, Ordnance Department, United States Reserve.

HAHN, CONRAD V., First Lieutenant, Division of American Ordnance Base Depot, France.

HALL, KEPPELE, Captain, Ordnance Department.

HALL, WINTHROP G., United States Army, Camp Devens, Mass.

HANDS, RONALD C., First Lieutenant, Ordnance Reserve Corps.

HART, HOWARD P., Ensign, United States Navy.

HAYS, JOHN C., Major Quartermaster's Department, United States Reserve.

HEILEMAN, FRANK A., First Lieutenant, Machine Gun Company, 54th Infantry.

HENDRICK, WALLACE M., First Lieutenant, 301st Engineers, United States Reserve.

HIBBARD, L. J., Lieutenant, 11th Regiment Engineers, France.

HODOUS, LOUIS W., Private, First Class, Section 542, United States Ambulance Service.

INGHAM, HOWARD M., Lieutenant (Junior Grade), United States Naval Reserve Force, Class 4.

JACKSON, J. H., Second Lieutenant, Ordnance Reserve Corps.

JACKSON, JOHN R., Captain, Ordnance Department, American Ordnance Depot in France, United States Reserve.

JACKSON, LUCIAN C., American Expeditionary Forces, France.

JACOBS, HENRY L., Camp Lee, Petersburg, Va.

KALEY, GEORGE B., First Lieutenant, Ordnance Reserve Corps.

KENT, ROBERT W., First Lieutenant, Officers' Reserve Corps, United States Army.

KINGSLEY, F., First Lieutenant, Officers' Reserve Corps.

KUGEL, H. K., First Lieutenant, Engineers' Reserve Corps, Company E, 310th Engineers, Camp Custer, Mich.

LANCASTER, W. C., Engineer Officers' Reserve Corps.

LAWRENCE, S. E., Captain, Engineer Officers' Reserve Corps.

LEWIS, F. H., Major, Ordnance Department, United States Army.

LIBBY, WILLIAM L., Lieutenant, Production Section, Gun Division, Ordnance Department, Washington, D. C.

LYNN, E. H., Captain, Coast Artillery Corps, United States Army.

LYNN, THOMAS H., Captain, Company H, Pennsylvania Reserve Militia Infantry.

MCCLELLAND, C. C., Company E, 306th Engineers, Camp Jackson, Columbia, S. C.

MCELROY, J. W., Captain, Ordnance Reserve Corps.

MCGRATH, F. P., First Pennsylvania Ambulance Company, 28th Division, Camp Hancock, Ga.

MCINTOSH, R. L., Captain, Ordnance Department, Officers' Reserve Corps.

MACLEAN, M. R., First Lieutenant, 9th Co. Infantry, Officers' Reserve Corps, Fort Niagara, N. Y.

MACLEOD, NORMAN M., First Lieutenant, Company S, United States Reserve, Camp Lee, Petersburg, Va.

MAIN, C. CURTISS, Signal Corps, United States Army.

MARSH, FRANCIS GRANT, Lieutenant, United States Navy.

MASON, EARL P., Lieutenant, United States Naval Reserve Force, Newport, R. I.

MATHER, HAROLD T., First Lieutenant, Coast Artillery Corps, Officers' Reserve Corps, Ft. Monroe, Va.

MAYNZ, T., Aviation Section, Signal Officers' Reserve Corps.

MEIXNER, B. A., First Lieutenant, Ordnance Reserve Corps.

METZ, W. R., Captain, Quartermaster Corps, United States Reserve, Fort Sam Houston, Tex.

MIDDLETON, HARVEY, Camp Funston, Kan.

MILLER, ERNEST P., JR., First Lieutenant, Ordnance Department, Officers' Reserve Corps.

MOON, H. A., Major, Rainbow Division, United States Army.

NIEMEYER, J. C. W., Captain, Quartermaster Reserve Corps, United States Army.

NORRIS, A. M., Ensign, U. S. S. *Missouri*.

PEASE, MAXFIELD, Machinist's Mate, First Class, United States Naval Reserve Force.

PHELPS, CLEON E., Second Lieutenant, Ordnance Department, United States Reserve.

PIRIE, H. L., Captain, Ordnance Department, British Expeditionary Forces, France.

POPE, HAROLD F., Captain, Quartermaster Officers' Reserve Corps.

POUND, JOSEPH H., Ordnance Department, 90th Division.

QUICK, RAY L., United States Naval Reserve Force.

RAYMOND, THOMAS E., First Lieutenant, Ordnance Department, Washington, D. C.

RIGGS, GEORGE, Sergeant, Company K, 107th Infantry.

ROGERS, JOHN I., Lieutenant (Senior Grade), United States Naval Reserve Force.

ROSS, HENRY B., First Lieutenant, Company F, 104th United States Engineers, United States Reserve.

RUBIN, HARRY E., First Lieutenant, Ordnance Reserve Corps, Machine Gun Section, Ordnance Department, Wilbur Wright Field, Fairfield, Ohio.

RUSSELL, FOSTER, First Class Private, Aviation Section, Signal Officers' Reserve Corps.

RYERSON, WILLIAM H., Captain, Class B, Engineer Officers' Reserve Corps.

SCHULTZ, WILLIAM W., Second Lieutenant, New Jersey Engineers.

SCRUGHAM, J. G., Major, Ordnance Reserve Corps, Production Section, Carriage Division, Ordnance Department.

SEARLE, DANA A., Ordnance Sergeant, Ordnance Corps, United States Army.

Sheldon, James Rhodes, Jr., First Lieutenant, 28th Company, Coast Artillery Reserve Corps, Ft. H. G. Wright, N. Y.
Shrady, C. D., Troop A, Squadron A, New York Guard.
Sibley, Mark Miller, Lieutenant (Junior Grade), United States Naval Reserve Force.
Smith, Charles W., Second Lieutenant, Signal Officers' Reserve Corps, American Expeditionary Forces, France.
Smith, Frederick C., Second Lieutenant, U. S. Reserve.
Smith, Thomas W., First Lieutenant, Engineer Officers' Reserve Corps, General Engineer Depot, Washington, D. C.
Snyder, William R., First Lieutenant, Ordnance Reserve Corps, United States Army.
Stone, M. A., Jr., Captain, Ordnance Officers' Reserve Corps.
Stovel, R., Major, American Expeditionary Forces, France.
Strahlmann, Otto E., First Lieutenant, Aviation Section, Signal Corps.
Staing, Joseph S., Captain, Ordnance Department, Gun Division, Production Section.

Taylor, Cyrus J., Chief Machinist's Mate, United States Naval Reserve Force.
Thomas, Charles W., Lieutenant (Senior Grade), United States Naval Reserve Force.
Thomas, John M., Lieutenant, Officers' Reserve Corps, Ft. Sill, Okla.
Thompson, Sanford E., Major, Officers' Reserve Corps, Office of Chief of Ordnance.
Tour, Reuben S., First Lieutenant, Ordnance Officers' Reserve Corps, Nitrate Division, Ordnance Department, Washington, D. C.
Tupper, Frederick G., Lieutenant (Junior Grade), United States Naval Reserve Force.

Van Syckel, F. T., Signal Corps, United States Reserve.
Voy, Edward L., Depot Battalion, 7th Regiment.

Werst, C. W., Lieutenant-Colonel, Russian Railway Service Corps.
Wieland, Charles F., Captain, Officers' Reserve Corps, United States Army, Manila Ordnance Depot, Manila, P. I.
Wing, Chester E., Ensign, United States Naval Reserve Force.
Woods, G. H., Captain, Quartermaster Corps, United States Army.
Woodward, H. W., Second Lieutenant, 106th Engineers, United States Reserve.
Wright, D. B., Second Lieutenant, 1st Division Staff, Engineer Officers' Reserve Corps, American Expeditionary Forces, France.
Wright, Paul D., First Lieutenant, Ordnance Department, Officers' Reserve Corps.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by February 17 in order to appear in the March issue.

CHANGES OF POSITION

A. R. Carlyle, who for the past ten years has been designing marine engineer for the Union Oil Company, of California, has terminated his relations with the company and has recently been made surveyor for the American Bureau of Shipping, American Lloyds, District of Southern Cal., Los Angeles, Cal.

Carl T. Hewitt, formerly connected with the Remington Arms Union Metallic Cartridge Company, Inc., Bridgeport, Conn., has accepted the position of metallurgist and testing engineer with the Fafnir Bearing Company, of New Britain, Conn.

George S. Blankenhorn, formerly connected with the Allis-Chalmers Manufacturing Company, of Milwaukee, Wis., as engineer in the department of the chief consulting engineer, has accepted a position with the American International Shipbuilding Corporation, of Philadelphia, Pa., in the department of machinery fabrication.

E. P. Worden has resigned his position of chief engineer for Henry R. Worthington to accept the position of mechanical engineer for the Submarine Boat Corporation, New York.

Alfred L. Aicher, chief draftsman with the F. J. Stokes Machine Company, Philadelphia, Pa., has accepted a position with the Southwark Foundry and Machine Company of the same city.

James Brakes, Jr., formerly in the employ of the Kimberly-Clark Company, Neenah, Wis., as testing engineer, has accepted the position of inspector in the power department of the Western Electric Company, Hawthorne plant, Ill.

Walter H. Rastall has become assistant sales manager for The Bauer Brothers Company, Springfield, Ohio. He was formerly affiliated with the Worthington Pump and Machinery Corporation, Cincinnati, Ohio, as engineer.

Edwin A. Moore has terminated his relations with the Union Switch and Signal Company, Swissvale, Pa., as works manager, and has assumed the duties of manager of the Liberty Ordnance Company, Bridgeport, Conn.

Henry Lindenkohl, until recently engineer of construction, American Locomotive Company, Schenectady, N. Y., has been appointed engineer of construction of the Worthington Pump and Machinery Corporation, with headquarters in New York. He will have charge of the design and construction of new shops and of additions to present shops.

Frederick J. Hardman, assistant examiner, U. S. Patent Office, Washington, D. C., has become associated with the patent department of the Dayton Engineering Laboratories Company, Dayton, Ohio.

B. D. Thompson, formerly superintendent of the L. O. Gordon Manufacturing Company, of Muskegon, Mich., has resigned and taken charge of the engineering and sales department of the Charles A. Strelinger Company, Detroit, Mich.

John K. Reckendorfer, formerly assistant secretary of the American Lead Pencil Company, New York, has become associated with the Naval Aircraft Factory, Navy Yard, Philadelphia, Pa., in the capacity of assistant to manager.

Francis L. Gilman has severed his connection with the Western Electric Company, New York, as assistant chief engineer, to take charge of the manufacturing departments of the National Conduit and Cable Company, Hastings-on-the-Hudson, N. Y.

F. J. Bryant, formerly affiliated with the Huber Hand Stoker Company, Passaic, N. J., in the capacity of New Jersey manager, has become partner in the firm of the Perfection Toy Craft Company, of West Brookfield, Mass.

Ralph Earl, until recently with the Pittsburgh Filter Manufacturing Company, Pittsburgh, Pa., has become associated with Morris Knowles, Inc., of the same city.

John D. Rogers has left the employ of the Virginia Railway Company, Princeton, West Va., to accept service in Russia.

George Endicott, for two and a half years mechanical engineer at The Morgan Spring Company, Worcester, Mass., has resigned to accept a position in the sales department of the Wickwire Steel Company, of Buffalo, N. Y. He will take up his new duties January 1, and will make his headquarters in Buffalo, N. Y.

K. T. Keller, until recently master mechanic with the Cole Motor Car Company, Indianapolis, Ind., has become affiliated with the Buick Motor Company, of Flint, Mich.

L. H. Thullen, formerly in the employ of the Hall Switch and Signal Company, New York, has assumed the duties of general manager of the Grand Rapids Brass Company, Grand Rapids, Mich.

ALLEN C. STALEY has severed his connection with the General Engineering Company, of Detroit, Mich., where he held the position of experimental engineer in charge of development work on the Doble steam car, and has become associated with the Stanley Motor Carriage Company, Newton, Mass., as research engineer in the same line of work.

ANNOUNCEMENTS

PARKER H. KEMBLE has entered the Sea Service Bureau at the National headquarters of Henry Howard, director of recruiting for the United States Shipping Board at the Boston Customhouse, for the duration of the war.

GEORGE E. CROFOOT has been promoted from instructor to assistant professor of mechanical engineering in the Towne Scientific School of the University of Pennsylvania, Philadelphia, Pa.

JOHN H. DEVISSER, of Detroit, Mich., has taken up his duties as Captain in the Ordnance Department and is at present stationed at the Frankford Arsenal, Philadelphia, Pa.

CLAYTON R. BURT, assistant general manager of the Russell Motor Car Company, Ltd., Toronto, Canada, has accepted a position as general manager of the same company, at Buffalo, N. Y., where a large new factory for the manufacturing of munitions for the U. S. Navy Department is being established by the company.

MONROE R. HULL, mechanical engineer for the Sissert Mining District Company, of London and Petrograd, has recently returned from Russia and will spend several months in the United States in the interests of the Sissert Company.

FREDERICK POPE, of Moses, Pope and Messer, Inc., consulting engineers, New York, has been commissioned a Captain in the 30th Engineers, which is the Gas and Flame Division.

C. P. COLEMAN, vice-president of the Worthington Pump and Machinery Corporation, has recently been elected president of the corporation.

CHANNING TURNER has received a commission as First Lieutenant, Field Artillery, Officers Reserve Corps, and has been ordered on active duty.

L. RICHARD DRESSLER has received a commission as First Lieutenant in the Ordnance Department, Carriage Division, Officers' Reserve Corps.

L. H. BERGMAN, formerly fuel engineer for the Nicetown Plant of the Midvale Steel and Ordnance Co., has gone into consulting practice under the name of American Industrial Engineering Co., with offices in the Monadnock Building, Chicago.

FRED L. PANCOAST has received a commission as Captain in the Ordnance Department, Officers' Reserve Corps, and has been assigned to active service.

FRANK P. RHAME has been commissioned as First Lieutenant in the Ordnance Officers' Reserve Corps.

CHARLES DAY has now returned from England and will assume active management of the probation department of the Emergency Fleet Corporation.

SANFORD E. THOMPSON, of Thompson and Lichtner, consulting engineers, Boston, Mass., has accepted a commission as major in the Ordnance Department, Officers' Reserve Corps. Mr. William O. Lichtner will carry on the work of the company.

J. G. SCRUGHAM has been commissioned as Major, Ordnance Reserve Corps, and assigned for duty to the Production Section, Carriage Division, Ordnance Department, Washington, D. C.

C. L. HALLADAY, of Jackson, Mich., has become associated with the Auto Industries Committee, of Washington, D. C.

ELMER R. RITTER has entered into active service as a First Lieutenant in the United States Ordnance Reserve.

KEPPELE HALL, of the firm of Thompson and Lichtner, consulting engineers, of Boston, has accepted a commission as Captain in the Ordnance Department and is now located at Washington, D. C.

MAJOR DABNEY H. MAURY, Engineer Officers' Reserve Corps, has closed his office in Chicago for the duration of the war. For some time past he has been in Washington looking after water-supply problems in connection with cantonment construction.

W. E. MOSHER has been appointed by the Secretary of War as assistant superintendent engineer in connection with Marine Refrigeration, Army Transport Service, Quartermaster Corps, U. S. A. Piers, at Hoboken, N. J.

MAJOR-GENERAL GEORGE W. GOETHALS, acting quartermaster general, has been appointed by the Secretary of War to serve also as director of War Department transportation and storage.

NECROLOGY

WILLIAM CHARLES ADAMS

William C. Adams was born in April 1883 in North East, Erie County, Pa. He was educated in the schools there and later attended the State Normal School. He also took a course in the International Correspondence Schools.

He served his apprenticeship as machinist with the Eureka Tempered Copper Works, North East Pa., from 1902 to 1903. He then located with the Brooks Locomotive Works, Dunkirk, N. Y., as machinist. In 1904 he became associated with the Bantam Anti-Friction Co., Bantam, Conn., as draftsman, and a little later worked in the same capacity for the Coe Brass Manufacturing Co., Torrington, Conn. In 1905 he returned to the Bantam Company as superintendent. In 1908 he took charge of the sewer works of the city of Torrington.

From 1909 until 1914 Mr. Adams was employed by the Chase Rolling Mill Co. and the Chase Metal Works Co., Waterbury, Con., as draftsman and engineer, and designed, constructed and maintained their hydraulic extrusion and rolling-mill machinery. Until the completion of the new plant of the Chase Metal Works Co. Mr. Adams had charge of the machine shop, drafting room, pattern shops and hydraulic plant of the Chase Rolling Mill Co. He took charge of the same departments in the new plant.

About March 1915 Mr. Adams became associated with the Kings Norton Metal Co., Ltd., Kings Norton, Birmingham, England, as works manager. He designed and superintended the erection of buildings and plant for the extrusion of non-ferrous metals in bars and sections. As a single unit the plant is regarded by experts as the largest and finest in the British Isles.

Mr. Adams was a member of the Birmingham Association of Mechanical Engineers, the Institute of Metals, London, and was honorary treasurer of the Birmingham Metallurgical Society. He became a member of the Society in 1914. He died on July 13, 1917.

ADOLPH THEODORE BRUEGEL

A. Theodore Bruegel, secretary of the Hess-Bright Manufacturing Co., Philadelphia, died at his home in Melrose Park on November 7, 1917. Mr. Bruegel was born on January 11, 1866, in Canton, O. He was educated in the St. Louis Manual Training School and later attended Lehigh University, being graduated in 1888 with the degree of M.E. He took a post-graduate course in Cornell University and received his M.M.E. degree in 1896.

During the summers of 1883 to 1885 he worked as machinist for the Missouri Malleable Iron Works and the Lehigh Valley Railroad Co. He obtained his drafting-room experience with the Johnson Steel Co., Johnstown, Pa. From 1888 to 1892 he acted as instructor in mechanical drawing and descriptive geometry in Cogswell Polytechnic College, San Francisco. For the next five years or so he was connected with Sibley College, Cornell University, as instructor in machine design. Later he took charge of the teaching of kinematics of machinery and also junior drawing.

In 1898 Mr. Bruegel became an instructor in mechanical engineering in Pratt Institute, Brooklyn, giving his attention principally to the steam and machine-design courses. For the last ten years he was associated with the Hess-Bright Manufacturing Co., Philadelphia.

He was a member of the Engineers' Club of Philadelphia, the Society for the Promotion of Engineering Education, the American Association for the Advancement of Science, the National Geographic Society, and the Philadelphia Chamber of Commerce. He became a member of the Society in 1900.

JOSEPH PHINEAS DAVIS

Joseph P. Davis was born on April 15, 1837, at Northboro, Mass. He was graduated from Rensselaer Polytechnic Institute in 1856 with the degree of C.E. Until 1861 he acted as assistant engineer on the construction of the Brooklyn Water Works. He then went to Peru, S. A., where he remained for four years in the employ of the government as topographical engineer. Upon his return he was made commissioner of parks in Brooklyn, N. Y.

About 1867 he was appointed chief assistant engineer on the construction of the St. Louis Water Works, later becoming chief engineer on the construction of the Lowell, Mass., Water Works. In 1872 he was appointed chief engineer of the Boston Water Board, and the following year was made city engineer of Boston, which position he held till 1880.

At that time Mr. Davis accepted a position with the American Bell Telephone Co. as chief engineer, holding the same position with its successor, the American Telephone and Telegraph Co., until 1905, when he retired from active business.

Mr. Davis was the consulting engineer of the Croton Aqueduct Commission from 1884 to 1886, of the Massachusetts State Board of Health from 1886 to 1904, of the Metropolitan Sewerage Commission, Mass., in 1898. He was vice-president and general manager of the Metropolitan Telephone Co., New York, from 1880 to 1886, and was president of the Hudson River Telephone Co. from 1889 to 1895, and of the Westchester Telephone Co. from 1890 to 1903.

Mr. Davis was a member of the American Society of Civil Engineers, the American Institute of Electrical Engineers, the

A. T. Bruegel

Institution of Electrical Engineers, England, and the Boston Society of Civil Engineers. He became a member of the Society in 1880. He died on March 31, 1917.

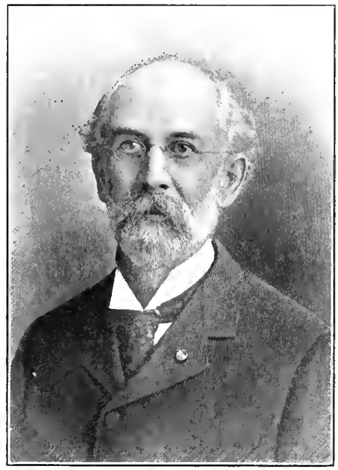
AUGUST A. HONSBERG

August A. Honsberg was born on May 18, 1841, in Boulay, Metz, France. He was educated in France, receiving his technical training in the Institution Carmentrez.

He served an apprenticeship from 1859 to 1861 with Kaut & Westmayer at St. Jean, Saarbrucken, Germany. The next two years he spent at the Ateliers des Chemins de Fer de l'Est, Montigny. He obtained his drafting experience from 1863 to 1865 in the Regimental School of Engineers, leaving there to go to l'Ecole Polytechnique, Metz. In 1866 he became superintendent of machinery at the Arsenal, Genie. He served during the Franco-Prussian War as chief of the engineering detachment, Fifth Army Corps.

About 1872 Mr. Honsberg came to the United States. His first position was with the Kings Bridge Co. Later he was associated with the Keystone Bridge Co. In 1881 he became master mechanic in charge of machinery and buildings of the Cleveland Rolling Mill Co. After ten years' service he resigned to take a position in the Cleveland city engineer's office in the bridge department, leaving this department after another ten years to enter the city water works office, to make plans for a new pumping station, engine and boiler house. For the last six years he was connected with the bridge and map department of the city of Cleveland.

Mr. Honsberg became a life member of the Society in 1901. He



Joseph Morgan, Jr.

was also a member of the Cleveland Engineers' Society. He died on October 21, 1917.

GUY EDWARD MITCHELL

Guy E. Mitchell was born on March 4, 1869, in Lowell, Mass. He attended the public schools of that city and later entered the Massachusetts Institute of Technology, from which he was graduated as a mechanical engineer in 1891.

He was employed for a number of years by the Boston and Maine Railroad and worked up from the position of chief draftsman to that of consulting engineer of that company. After leaving the Boston and Maine Railroad he was located in New York for about three years as consulting engineer. He then served in various important capacities in the building of the Berkshire trolley system. Upon the completion of that work he became associated with the Alden Sampson Co., Pittsfield, builders of large automobile trucks, and acted as general manager for a period of seven years. Later he assisted in the building of the Hampden Railroad.

In December 1914 he was appointed manager of the municipal gas and electric light plant, Westfield, Mass. He held this position at the time of his death.

He became a member of the Society in 1903. He died on October 18, 1917.

JOSEPH MORGAN, JR.

Joseph Morgan, Jr., was born on July 27, 1842, in Philadelphia. He was educated in the Central High School of that city, devoting himself to the sciences. In the fourth year of his course he entered the steam-engineering corps of the United States Navy. In 1861 he entered active service as third assistant engineer. In 1863 he was promoted to second assistant engineer. In 1866,

after the war, he resigned and entered the service of the Phenix Iron Co., Phenixville, Pa., as draftsman. In 1868 he had risen to be chief draftsman, when he resigned to take a similar position with the Edgemoor Iron Co. About 1879 Mr. Morgan became associated with the Cambria Iron Co., Johnstown, Pa., as draftsman. He was made chief engineer in 1881, and after twenty-five years' service in that capacity was relieved of his more active duties and made consulting engineer of the Cambria Steel Co.

Mr. Morgan designed and superintended the various parts of the works of that firm, including six blast furnaces, new bessemer works of the largest class, new blooming mill, open-hearth plant, rail mills and various large mills of the Gautier plant involving the expenditure of millions of dollars. He was the consulting engineer in charge of the building of the Quemahoning Dam in 1913, and later the Saltlick Dam.

In 1881 Mr. Morgan went abroad to make a study of gun and armor forgings. He visited the principal cities of England and the Continent where armor-making works were located. Later he was appointed a member of the United States Fortification Board, and wrote several valuable papers to aid in instructing the public on the subject, as well as for the information of Congress. Mr. Morgan was familiar with the art of steel making from the date of the inception of the bessemer process up to the present time.

Mr. Morgan was a member of the United States Naval Institute and the Grand Army of the Republic and also held many offices in fraternal organizations. He was vice-president of the Society from 1886 to 1888 and was chairman of the Sub-Committee on Iron and Steel for the year 1913-14. He became a life member of the Society in 1881. He died on December 9, 1917.

JOHN RIDDELL

John Riddell, mechanical superintendent of the Schenectady Works of the General Electric Company, died in Schenectady, N. Y., December 31, 1917. He was born in Ireland in 1852 and was conspicuously a self-made man. At the age of about 13 years, in Jersey City, he started as an apprentice in the jobbing machine shop of Nicholas B. Cushing, who made elevators and repaired machinery, especially marine engines. This work brought him in contact with marine circles, which resulted in his later serving two years as second engineer on trading steamers plying between the West Indies and Central America and New York.

His first association with the electrical business was with the Daft Electrical Co. where he did considerable experimental mechanical work in the railway field. In 1887 he entered the employ of the Thomson-Houston Electric Co. at Lynn, Mass. In 1888 he became foreman of the railway motor shop and was recognized as one of the leading mechanical experts at the time the General Electric Co. was formed in 1892.

Mr. Riddell moved to Schenectady in 1895, and shortly after his arrival was appointed mechanical superintendent of the company. In this important position he designed and had built special machine tools for increasing the production of the machine shops and also for carrying on the many special processes involved in the manufacture of mechanical tools. He was consulted in regard to all automatic machinery and his resourceful genius was called in when a solution was sought for different mechanical problems of a baffling nature. The records of the United States Patent Office show that 37 patents were taken out in his name.

In the sense that Mr. Riddell could obtain large outputs from machine shops with a minimum cost, he might well be termed a manufacturing economist. He was responsible for the location of machines and machine tools and his advice and opinion were sought in regard to such manufacturing problems as the routing of the materials from the time the raw materials were received until the finished product was ready for shipment.

Among the notable achievements of Mr. Riddell in the various works of the General Electric Co. is a boring mill—the largest in the world when made—which was built from his design and which has a 60-ft. swing. This was so successful for machining the large wheels for the rotors and stators of water-wheel-driven generators that he designed a 10-ft. boring mill embodying the same principles as the larg one, which is used for turbine work. These mills have operated ight and day for over ten years without the loss of a single hour.

Another one of his desigas was a bucket-cutting machine for large steam turbines which he developed in 1902. It was at this time that the General Electric Co. was building the first 5000-kw. steam turbine ever constructed, and this labor- and time-saving device became an important factor in the development of the steam-turbine industry at the time when the steam engine was preëminent in the largest power plants in the world.

Almost automatic was the field-coil-winding machine which he built and which was adopted both in Lynn and Schenectady. It was a labor saver and a time saver, and in the opinion of many persons there was no single achievement of Mr. Riddell's which advanced the electrical industry more than did this winding machine.

Mr. Riddell was a member of the Engineers' Club of New York and the Society of Engineers of Eastern New York. He became a member of the Society in 1895. During his later years he de-

John Riddell

livered several papers on engineering subjects before various associations.

He was awarded a gold medal at the Panama-Pacific International Exposition at San Francisco in 1915, as collaborator in the Exhibit of the General Electric Co. at the Exposition.

HAROLD VAN DUZEE

Harold Van Duzee was born in West Newton, Mass., on April 4, 1859. He attended the public schools of that city and later entered the engineering department of the Massachusetts Institute of Technology. He spent one year in miscellaneous drafting work for Frederick Tudor & Co. and for the Hinkley Locomotive Works, both of Boston, Mass. For two years he was associated with Col. George E. Waring of Newport, R. I., as draftsman and was his assistant on sewage and drainage work in Memphis, Tenn., where he remained for about a year. The second year of this work he had charge of the sewage disposal of the Bryn Mawr Hotel. His next position was with the Tide Water Oil Co., Bayonne, N. J. At the time of his death Mr. Van Duzee was in private practice in Philadelphia as a civil and sanitary consulting engineer.

Mr. Van Duzee did much to beautify the suburban homes of Philadelphia, working in this connection with the Olmstead Bros. of Brookline, Mass. He also collaborated with Mr. F. W. Taylor in the scientific development of sod for golf grounds.

He became a Junior member of the Society in 1885. He died on May 7, 1917.

WILLIAM FORGUE WAY

William F. Way was born on October 3, 1888, in Johnstown, N. Y. He was graduated from Rensselaer Polytechnic Institute in June 1913 with the degree of mechanical engineer. His shop experience was obtained in Hutton's Machine Shop, Seattle, Wash. Later he became associated with the Talbot Boiler Co., Seattle, as draftsman. He became a Junior member of the Society in 1916. He died on December 18, 1916.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER MARCH 10

BELOW is the list of candidates who have filed applications since the date of the last issue of THE JOURNAL. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate or Associate-Member, those in the third class under Associate-Member or Junior, and those in the fourth under Junior grade only. Applications for change of grading are also posted. Total number of new applications, 112.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. All correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by March 10, and providing satisfactory replies have been received from the required number of references, they will be balloted upon by the Council. Those elected will be notified about April 15.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be slower than under normal conditions.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

California

PITTS, HAROLD P., Industrial Engineer, Pacific Gas & Electric Co., San Francisco

Colorado

ORR, CARLETON A., Superintendent Power Plants and Shops, Arkansas Valley Railway, Light & Power Co., Pueblo

Connecticut

AVIS, SAMUEL W., Mechanical Engineer, Hartford Special Machinery Co., Hartford

BRITTAN, FREDERICK A., Engineer, Remington Arms & Ammunition Co., Bridgeport

TOMS, ROLLIN T., Foreman Stock Tool Department, Yale & Towne Mfg. Co., Stamford

District of Columbia

BARRETT, CHARLES G., Assistant Engineer, U. S. Shipping Board, Emergency Fleet Corp.

BASCOMBE, FRANK J., Assistant Superintendent, Washington Steel & Ordnance Co.

BLACK, JOHN S., Captain Ordnance Reserve Corps, U. S. A.

MARTIN, H. T., Captain Ordnance Reserve Corps, U. S. A.

Delaware

MAGUIRE, CHARLES F., Design Engineer, E. I. du Pont de Nemours & Co., Wilmington

Illinois

CAREY, JAMES L., Architect and Engineer, Chicago

PEACH, WILLIAM M., Chief Draftsman, Pullman Mfg. Co., Pullman

STUART, WILLIAM K., Assistant Secretary, Western Steel & Fdy. Co., Chicago

Indiana

CRAVENS, GEORGE W., Chief Engineer and Works Manager, Elkhart Carriage & Motor Car Co., Elkhart

Kentucky

ANDERSON, WARWICK M., Professor of Physics, University of Louisville, Louisville

Louisiana

DOBREE, BASIL S. T., Chief Engineer, Panama Ice Co., New Orleans

Maryland

HIND, THOMAS W., Consulting Engineer, The Crown Cork & Seal Co., Baltimore

Michigan

LINK, VINCENT, Consulting Engineer, Studebaker Corp., Detroit

Minnesota

BOOTH, GEORGE, Works Managing Engineer, Pan Motor Co., Saint Cloud

REES, ELIAS, Fuel Engineer, C. L. Pillsbury Co., Minneapolis

ZIMMERMAN, FRANK R., Chief Engineer, National Iron Co., Duluth

Missouri

CANAVAN, ASA L., Southwestern Representative, W. H. Miner, Grover

TALEN, MAURITZ W., Chief Draftsman, The Ruemmeli-Dawley Mfg. Co., St. Louis

TOENSFELDT, KURT, Principal Assistant Mechanical Engineer, St. Louis Water Works, St. Louis

New Hampshire

CUMMINGS, FRED A., Resident Engineer, Nashua Mfg. Co., Nashua

New Jersey

CARLTON, JOSEPH R., Mechanical Testing, Public Service Electric Co., Newark

SCHEEL, JOHN B., Production Manager, New Jersey Brass Corp., Garfield

New York

BASTIAN, FREDERICK G., Mechanical Foreman, Lackawanna Steel Co., Lackawanna

BEEBEE, LEWIS, Mechanical Engineer, Hammond Steel Co., Inc., Syracuse

COCHRANE, LEWIS, Chief Engineer, New York *Times*, New York

GRONBECH, CHRISTIAN E. A., Superintendent and Assistant Factory Manager, C. J. Tagliabue Mfg. Co., Brooklyn

HULST, JOHN, Assistant to Vice-President, and Chief Engineer, United States Steel Corp., New York

KAY, GEORGE A., with E. W. Bliss Co., Brooklyn

KIRKHAM, CHARLES B., Chief Designing Engineer, Curtiss Aeroplane & Motor Corp., Buffalo

MORSE, EDWARD P., Jr., General Superintendent, Morse Dry Dock & Repair Co., Brooklyn

PEET, EDWIN B., Mechanical Engineer, E. W. Bliss Co., Brooklyn.

STARK, ARTHUR W., Assistant to Engineer of Construction, Consolidated Gas Co. of N. Y., New York

TAGGART, JAMES M., Consulting Engineer, Engineering Department, Interborough Rapid Transit Co., New York

WALSH, GEORGE. W., Mechanical Engineer, C. E. Knoeppel & Co., New York

Ohio

BAILY, THADDEUS F., President, The Electric Furnace Co. of America, Alliance

TUECHTER, AUGUST H., President, The Cincinnati Bickford Tool Co., Cincinnati

YANNEY, GEORGE W., Chief Draftsman, Alliance Machine Co., Alliance

Oklahoma

MEYER, BARNEY, Mechanical Superintendent, Cosden & Co., Tulsa

Oregon

DICKSON, JOHN, Superintendent Motive Power, Spokane, Portland & Seattle Rwy., Oregon Electric Rwy., and Spokane & Inland Empire Rwy., Portland

Pennsylvania

GILDERSLEEVE, FRANK M., Assistant Mechanical Engineer, Ridgway Dynamo & Engine Co., Ridgway

KAVANAUGH, RAMSEY D., Foreman of Road Tests, Pennsylvania R. R. Co., Altoona

RAPP, JESSE P., Chief Inspector, Purchasing Department, American International Shipbuilding Corp., Philadelphia

SUPPLEE, WARREN P., Chief Operating Engineer of Power Stations, The Eastern Penn. Light, Heat & Power Co., Pottsville

Rhode Island

SWASEY, CORNELIUS B., Superintendent, Allens Ave. Plant, Gorham Mfg. Co., Providence

Tennessee

ROBINSON, G. A., Mechanical Superintendent, La Follette Coal & Iron Co., La Follette

Texas

LEARMONTH, ALEXANDER C., Chief Engineer Power Plant, El Paso Electric Rwy. Co., El Paso

Virginia

DAVIS, GEORGE M., Locomotive Designer, Norfolk & Western Rwy. Co., Roanoke

HIGGINS, EDMUND S., 2nd Assistant Manager, Hopewell Works, Du Pont Powder Co., City Point

LEPS, HENRY M., Lieutenant (j.g.), U.S.F.N.R., Engineering Assistant, Office of Aide for Material, Norfolk

Wisconsin

BRINTZINGER, CHARLES H., Appraisal Engineer, American Appraisal Co., Milwaukee

Wyoming

BRENNAN, WILLIAM D., Assistant General Manager, The Union Pacific Coal Co., Cheyenne

Canada

CARPENTER, FRANK G., Superintendent Plant and Chief of Construction and Engineering, P. Burns & Co., Ltd., Calgary

Cuba
GOIRIGOLZARRI, MANUEL, Manager, Havana Marine Railways, Inc., Havana

China
HOPKINS, R. D., with the China-American Trading Co., Inc., Tientsin

Norway
BASSOE, CARL F., Engineer, Norsk Aluminum Co., Kristiania

Japan
TAKETA, HIDEJI, Mechanical Engineer, Ashio Mines of Furukawa Mining Co., Shimotsuke

South America
MACWHIRTER, GEORGE E., Operating and Constructing Engineer, Boquete Nitrate Co., Antofagasta, Chile
ANSALDO, PEDRO, Chief Engineer and General Manager, De La Compania Industrial De Electricidad, Buenos-Aires, Argentina

FOR CONSIDERATION AS ASSOCIATE OR ASSOCIATE-MEMBER

Alabama
EPHGRAVE, HERBERT, Chief Engineer, Joubert & Goslin Machinery & Fdy. Co., Birmingham

Connecticut
LANNON, JOHN D., Assistant Superintendent of Manufacturing, Remington Arms U. M. C. Co., Bridgeport

Indiana
SUTLIFF, JAMES T., Advertising Manager, The Connersville Blower Co., Connersville

Maine
ROWE, LOUIS G., Production Engineer, Eastern Mfg. Co., South Brewer

Michigan
WATSON, HARRY J., Instructor in Mechanical Engineering, University of Michigan, Ann Arbor

New Jersey
KELLEY, JOSEPH A., Designer Special Machinery, Edison Storage Battery Co., Orange

New York
AKERLY, HAROLD E., Industrial Engineer, Eastman Kodak Co., Rochester
BLOMGREN, HERBERT, Assistant Engineer, Westinghouse, Church, Kerr & Co., New York

Washington
BUCKINGHAM, JAY E. E., Assistant General Manager, Hofius Steel & Equipment Co., Seattle

Wisconsin
KOSKINEN, EINAR T., Draftsman, Nordberg Mfg. Co., Milwaukee

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

Illinois
CUNNINGHAM, JAMES D., President, Republic Flow Meters Co., Chicago
KELLY, ROY C., Chief Engineer, Moline Pressed Steel Co., Moline
PRATT, JABEZ H., Chemical Engineer, The Liquid Carbonic Co., Chicago

Indiana
SAUNDERS, FRED S., Charge of Planning Department, Diamond Chain Mfg. Co., Indianapolis

Massachusetts
BOSWORTH, RALPH L., Designing Engineer, Crocker-McElwain Co., Holyoke
MCKECHNIE, ALEXANDER B., Sales Engineer, The Merrill Process Co., Boston

New Jersey
SMITH, CHESTER F., Assistant Superintendent, Case & Can Department, Standard Oil Co., Bayonne
STENKEN, HARRY A., Assistant Engineer, American Sugar Refining Co., Jersey City

New York
MITCHILL, GEORGE L., Chief Inspector, Electric Bond & Share Co., New York City
UNDERHILL, JACOB, Inspector of the Contract & Inspection Department, New York Edison Co., New York City

Pennsylvania
ALLEN, EDWARD G., Marine Engineer and Supervising Draftsman, Philadelphia Navy Yard, Philadelphia
BATTLE, JOHN R., Mechanical Engineer and Philadelphia Manager, Swan & Finch Co. of New York, Philadelphia
PETERS, FRANCIS C., Mechanical Engineer, The New Jersey Zinc Co., Palmerton
TAFEL, THEODORE, Jr., Standard Sanitary Mfg. Co., Pittsburgh

FOR CONSIDERATION AS JUNIOR

California
DUNCAN, GEORGE W., Jr., Consulting Mechanical Engineer, San Francisco

Connecticut
BENSON, CARL N., Mechanical Draftsman, S. K. F. Ball Bearing Co., Hartford
STOCKMANN, ERLING B., Inspector of Ballistics, Remington Arms-U. M. C. Co., Bridgeport

District of Columbia
ANDRAE, WILLIAM C., Laboratory Assistant, Bureau of Standards
HARTMAN, CLARENCE O., Draftsman, Ord Dept., Field Carriage Div.
SEARLE, RUSSELL M., Draftsman, Gun Division, Ordnance Bureau, U. S. A.

Florida
BOEHNLEIN, CHARLES, Aeronautic Draftsman, Naval Air Station, Hull Drafting Department, Pensacola

Massachusetts
JOHNSON, HAROLD S., Erecting Engineer, Westinghouse Electric & Mfg. Co., Boston
McNALLY, EDWIN M., Cadet, U. S. Naval Reserve Flying Corps, Bureau Steam Engineering Naval Aviation Detachment, Mass. Inst. of Tech., Cambridge

Michigan
HELLER, LEWIS W., Graduate Student, University of Michigan, Ann Arbor

New Jersey
BROWN, J. LYALL, Mechanical Designer, Crocker-Wheeler Co., Ampere
TERRY, CARLYLE M., Assistant Engineer Power House, Babcock & Wilcox Co., Bayonne

New York
CROCKETT, CHARLES H., Research Engineer, Troy
BRUMBLE, WILLIAM C., Mechanical Draftsman and Engineering Assistant, New York Central Railroad, New York City
GORDON, MERRITT W., Cadet Engineer, Fulton County Gas & Electric Co., Gloversville
MARKLEY, WILLIAM F., Engineer, Western Union Telephone Co., New York City
NAUMANN, WILLIAM H., Chief Inspector U. S. Government, Artillery Ammunition, Inspection Section Ordnance Department, New York City
SPELLMAN, CHARLES B., Draftsman, Niagara, Lockport & Ontario Power Co., Lyons

Ohio
INDERBITZIN, ALEXANDER M., Mechanical Engineer, East Iron & Machine Co., Lima
SHIRLEY, HARVEY J., Machine-Tool Designer and Checker of Design, Lodge & Shipley Machine Tool Co., Cincinnati

Oklahoma
HOFFMAN, RAY T., Construction Engineer, Sapulpa Electric Co., Sapulpa

Pennsylvania
HOFFER, HOWARD A., Engineer, Special Castings Department, U. S. Cast Iron Pipe & Fdy. Co., Philadelphia
MAGOUN, JOHN W., Assistant Engineer of Tests, Steelton Plant, Bethlehem Steel Co., Steelton

Vermont
BRILL, ELLIOT M., Manager Cost Dept., Jones & Lamson Machine Co., Springfield

China
GREENWOOD, HEMAN C., Chief Instructor of Mechanical Engineering, Hunan Polytechnic Institute, Changsha

APPLICATIONS FOR CHANGE OF GRADING

PROMOTION FROM ASSOCIATE

New York
ROGERS, FRED E., Editor *Machinery*, New York

PROMOTION FROM ASSOCIATE-MEMBER

Massachusetts
GUNNING, WILLIAM A., Head Draftsman, American Optical Co., Southbridge

New York
BORIE, RENSHAW, Engineer Hoist Department, The Yale & Towne Mfg. Co., New York

PROMOTION FROM JUNIOR

Illinois
BRYEN, THOMAS T., with Williams, White & Co., Chicago (Reinstatement)

New York
FLAGG, SAMUEL B., Fuel Expert, Electric Bond & Share Co., New York
WANDEL, CARLETON, Lumber Salesman, with C. H. Pearson, New York
WEBER, H. F., with Compression Engineering Corp., New York

SUMMARY

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping anyone desiring engineering services. The Society acts only as a clearing house in these matters.

IN forwarding applications, stamps should be enclosed for transmittal to advertisers; applications of non-members should be accompanied by a letter of reference or introduction from a member, such reference letter to be filed with the Society.

GOVERNMENT REQUESTS

The Society has been asked to make suggestions of men for the following positions with the Government. Non-members possessing the necessary qualifications may avail themselves of these notices by enclosing with their reply a personal introduction to the Secretary. Kindly advise this office what action you have taken.

MEN competent to take over the maintenance and supply work for aero squadrons. Those qualifying must be over the draft age, but in cases of exceptional ability commissions will be issued to those in the draft age. 2574.

INSPECTION MEN FOR AERONAUTICAL ENGINES. 2575.

ENGINEERS FOR REPAIR STATION for the vessels of this Service in a port of France. Men to serve in a military or civilian capacity. Commissions in the U. S. Officers' Reserve Corps, and consideration may also be given to applicants within draft age. 2580.

INSPECTION MEN ON CARTRIDGES. Those above draft age and who show high qualifications will be commissioned. 2581.

DESIGNERS AND CONSTRUCTION ENGINEERS, mechanical and civil. 2564.

ASSISTANT GENERAL SUPERINTENDENT for woodworking and ironworking plant employing 3000 men. Age 30 to 40 years. Technical education required, with five or more years' práctical experience in handling men. Location Indiana. 2566.

TIME-STUDY MAN for small manufacturer making small stampings and brass goods. Should be conversant with modern cost accounting and able to make correct cost estimates. Location Michigan. 2567.

WORKS MANAGER. Must be familiar with the handling of help and the manufacture of small tools such as taps and dies. Young man preferred. Location Massachusetts. 2571.

JIG AND SMALL-TOOL DESIGNER, good on experimental work on steam specialties; eventually to head engineering department. Location New York City. 2572(a).

TIME-STUDY MEN. Two to four high-grade men desired. 2572(b).

MECHANICAL ENGINEER to take charge of the entire mechanical end of business, in a new position created by the growth of company in New England States. Man of more than ordinary ability. Salary $4000 to $6000 at the start. 01.

MASTER MECHANIC for large central power plant. Permanent position with chance for advancement. State age, experience, salary expected and position regarding draft. 04.

YOUNG MAN with school education at least and preferably with one or more years in college, probably not subject to draft, to enter engineering organization at nominal salary. Chance for advancement will depend upon ability of applicant. Experience along sugar-machinery lines of considerable assistance. Location New York City. 012.

GENERAL MANAGER for an old established Chicago plant manufacturing light and heavy machinery, special tools, etc. Man of 45 to 55 years of age preferred. Location Illinois. 07.

MECHANICAL DRAFTSMAN. Salary $20 to $25. Location New York. 09.

FIRST-CLASS DRAFTSMAN experienced on heavy engines and accustomed to handling work with only general supervision; also good detailers. Give full particulars in first letter. Location Ohio. 011.

POSITIONS AVAILABLE

SALES ENGINEER. Young engineer, to sell and supervise installation of steam traps and temperature regulators. Steady promotion offered. 2483.

CHIEF ENGINEER versed in refrigeration and producer-gas-engine work. Salary $2400 to $3000. Location, 50 miles from Baltimore. 2488(a).

SIX MEN to operate anthracite gas producers. Salary $21 a week, eight-hour shift. 2488(b).

TURBINE OPERATING ENGINEERS, high-class. Two or three young men with good education and some practical experience. 2492(a).

SWITCHBOARD OPERATORS who have had experience in large stations. Two or three, preferably, young men with good education to qualify for responsible positions on this line of work. 2492(b).

YOUNG TECHNICAL GRADUATE in mechanical engineering with four or five years' factory experience for position of assistant engineer. Good opportunity for advancement. 2501.

OPERATING ENGINEER for industrial plant located near Chicago. Must be a technical graduate and have had practical operating experience in power plants, and be capable of handling a power proposition involving approximately 5000 boiler hp. State age, experience in detail, and salary expected. 2445.

COLLEGE GRADUATES, ENGINEERS. Men out at least a year, for general shop engineering work with growing concern. Work leads to industrial management. State full particulars. 2478.

ELECTRICAL ENGINEER for plant in northern Ohio. Must assume (1) full charge of all electrical layout work, (2) supervise purchase of all electrical material and equipment, (3) act in an advisory capacity on all electrical equipment and installations after such have been turned over to the manufacturing departments within the plant, (4) attend to maintenance and upkeep, and (5) assume full charge and supervision of all new electrical installations. 2521.

OPERATING ENGINEERS for munitions plant. Men with practical field experience. Young technical graduates preferred. Salaries from $150 to $200, depending upon men. Positions located in Pennsylvania, Alabama, and Illinois. 2532.

FIRST-CLASS DRAFTSMAN experienced on heavy engines and accustomed to handling work with only general supervision. Give full particulars in first letter. 2533(a).

GOOD DETAILERS. Give full particulars in first letter. 2533(b).

YOUNG TECHNICAL GRADUATE, preferably a mechanical engineer who has had at least a small amount of shop experience, to act as time-study man. Salary to start $125 to $150 per month. Location Connecticut. 2534.

EXPERIENCED DESIGNER on electric baggage-truck work. Work would be the design of two- and four-wheel steer trucks, tractors and trailers. Location New York. 2535.

CHIEF DRAFTSMAN with executive and engineering ability, competent to direct work of large drafting room. Should be technically educated, have knowledge of hydraulic and mechanical engineering and be experienced in surveying and making finished plans of industrial plants. Write, stating nationality, age, education, experience in detail, present responsibilities and salary expected. Excellent opening for a capable, experienced and energetic man. Location Massachusetts. 2539.

TECHNICALLY EDUCATED MEN between 31 and 40 years of age. Three or four wanted for large engineering bureau making inspections of industrial properties. Technical education along mechanical and hydraulic lines important. Good openings for the right men. Give nationality, age, education, experience in detail, and salary expected. Location Massachusetts. 2540.

YOUNG MAN Technical graduate or man with practical shop experience who is familiar with blueprints and can readily read specifications, to develop as a sales engineer. Sufficient inducements to make the position valuable. Salary proportionate to merit and results. Location New York. 2545.

MECHANICAL ENGINEER for valuation department of chemical plant. Salary $125 to $150 per month. Location New Jersey. 2549.

MEN WITH TECHNICAL EDUCATION AND EXPERIENCE, not subject to military call, for long-established company operating steel and iron foundries and machine and forge shops, whose varied products are sold to the Government, railroads, mining and contracting industries, etc. State full particulars, kind of position preferred and salary expected. Location New Jersey. 2552.

TECHNICAL GRADUATE for fuel-economy work in connection with boiler operation, heating furnaces, and gas producers. Location Pennsylvania. 2559.

HEATING AND VENTILATING ENGINEER to supervise design, installation and work in advisory capacity in connection with maintenance in large rubber factory in northern Ohio. Salary commensurate with training, experience, and ability to handle men. Splendid opportunity for the right man. 2561.

TECHNICAL CORRESPONDENT capable of issuing orders for mechanical work. Location New York. 2562

MEN EXPERIENCED IN PLANT MAINTENANCE OR SHOP OPERATION for plant maintenance branch of the Western Electric Company. College education not necessary in all cases provided men have a fairly broad practical experience. Salaries from $1000 to $2000, depending upon qualifications of applicant. Opportunities for advancement for those who possess initiative and ability. 2563

TOOL DESIGNER who is resourceful and can follow work through to completion. Technical man with practical shop experience. Location Connecticut. 185.

ESTIMATOR for New York concern engaged as engineers and contractors for power plant, ventilation, and steam and hot water heating. 2103.

CHIEF ENGINEER to take charge of designing of railroad equipment and supplies, including motor cars, hand, push and velocipede cars, and locomotive standpipes. Technical graduate preferred, and as line is highly competitive, a man who can look at matters from a business as well as a strictly engineering point of view. Salary secondary consideration if right man can be secured. Location Middle West. 2247.

CORRESPONDENT for engineering computation department and to handle engineering correspondence, man or woman, preferably a technically educated person. Location Massachusetts. 2284.

YOUNG ENGINEER experienced in general plant construction work. Good opportunities for advancement. Preferably a man who is exempt from military duty. Location Illinois. 2286.

SUPERINTENDENT for machine shop manufacturing high grade printing machinery. Must be a good executive and thoroughly versed in modern methods of interchangeable manufacturing. Location near New York. Salary depends upon individual. Give age, nationality and complete experience. 2301

RECENT GRADUATES in mechanical engineering from schools of recognized standing desired for testing work in large steam-operated electric power plants. Applicants with experience in testing work and now located in and around New York City will be given preference. State particulars of education, experience and salary desired. 2345

ENGINEER familiar with abrasive processes as engineering sales manager with concern manufacturing metal finishing tools and equipment. Location New York State. 2346

MECHANICAL DRAFTSMAN OR YOUNG ENGINEER for drafting on refrigerating machinery and installation work. Salary depends upon man. Location New York City. 016

SALES MANAGER. Engineer experienced in estimating and selling to hold responsible position in long-established engineering and contracting business of an incorporated company, with possible opportunity to become financially interested. State age and experience. 017

INSTRUCTORS. The Department of Mechanical Engineering, University of Illinois, Urbana, Ill., needs a number of instructors in laboratory work, in machine design, and steam and gas-power engineering. Applicants should send a full statement of their educational training and practical experience with a recent photograph, addressed to Dean C. R. Richards. 018

MEN AVAILABLE

EXECUTIVE, SALES ENGINEER, now holding a responsible position as department manager in charge of design and sale of steam specialties, desires similar position with company having larger field and offering better future prospects. Age 35, married. Available on 30 days' notice. Location New York or Philadelphia preferred, but not essential. Minimum salary $4500. B-35.

WORKS MANAGER OR SUPERINTENDENT. Technical graduate, 20 years' experience from foreman to manager; successful executive with experience in modern systems of plant management. Minimum salary $5000. B-36.

EXECUTIVE PURCHASING ENGINEER with successful record in governmental, railroad and industrial service. Experienced in plant design and maintenance, in railroad valuation and in the purchase of electrical, mechanical and structural equipment and materials. At present connected with large corporation completing extraordinary program. B-37.

EXECUTIVE ENGINEER, age 40. Experienced estimator and designer of plants, particularly elevating conveying installations; also experienced in structural steel and plate work. Willing to invest capital in a plate or machine shop. Size not important but prospects must be good. B-38.

MECHANICAL ENGINEER AND PRODUCTION EXECUTIVE, age 37. Fully trained and practically experienced as tool and die maker, foreman and supervisor of engineering, manufacturing, tool and experimental departments. Well grounded in plant layouts and modern manufacture of interchangeable parts, small, medium and heavy. Knows how to handle men to get coöperation. At present employed but desires change owing to lack of opportunity for future advancement. B-39.

MECHANICAL ENGINEER. Technical graduate with eight years' experience in designing, erecting and operating power-plant and manufacturing equipment. Also experienced in specification and purchase of equipment. Desires position as mechanical superintendent or works engineer. B-40.

CHIEF ENGINEER AND RESEARCH EXPERT with 16 years' practical training in oil- and gas-engine development work. Broad experience in the fine points of both the technical and business side of engineering, with special aptitude for research work and the perfection of new ideas. Thoroughly competent to handle men, and to take charge of the development, design and supervision of construction of either marine or stationary internal-combustion engines. At present employed. Best of references. B-41.

PRODUCTION MANAGER, EFFICIENCY ENGINEER, SUPERINTENDENT OR TOOL ENGINEER. High-grade executive with 15 years' practical and technical experience in manufacturing covering every branch of the business except sales. Expert on tools and equipment, cost methods and time study. Competent to install piece work or bonus system. Until recently efficiency engineer with large automobile company: Business man looking for competent adviser on matters pertaining to manufacturing would find applicant the possessor of an attractive personality and good mixer and diplomat. Salary $3500. B-42.

MECHANICAL ENGINEER. Technical graduate with 20 years' experience in the design, construction and operation of power plants. Also familiar with building construction and the maintenance and operation of large buildings. B-43.

MECHANICAL ENGINEER. Technical graduate, age 25, with three years' experience in varied engineering work, desires position in engineering or engineering sales. Salary $1500. B-44.

PRACTICAL MAN, 42 years of age, with self-acquired technical training, desires position where initiative in labor saving, interchangeability of parts and standardization of methods are needed. Nine years' experience in machine shop, including construction and outside work, 3 years in charge of equipment installation for new plant, 8 years as designing draftsman, and 4 years' office training along industrial-engineering lines. At present employed, but desires opportunity to broaden. B-45.

MECHANICAL ENGINEER. Technical graduate with 7 years' manufacturing experience desires position as assistant-production manager. At present employed in executive position. B-46.

INDUSTRIAL ENGINEER. Technical graduate with two years' experience in time study, cost system, scheduling, planning, etc.; four years as draftsman on heavy machinery, transmission machinery, industrial-plant and power-plant equipment. At present employed but desires change where ability to produce results will be appreciated. B-47.

MECHANICAL ENGINEER. Technical graduate with 12 years' experience in the design and operation of power plants desires a permanent position with reliable concern. Cleveland preferred as location. B-48.

MECHANICAL ENGINEER with technical education and 17 years' experience in the design, construction and operation of industrial plants desires position as mechanical engineer or works manager. Competent to take charge of work from inception to operation of finished plant. Has had experience in organizing and handling work in Spanish-speaking countries and would take position away from home at present if conditions were made sufficiently attractive. B-49.

MECHANICAL ENGINEER who has specialized on drop forgings desires to make a change; reasons on request. Age 32, married. American-born of American parents, absolutely reliable and total abstainer. Desires permanent position with reliable concern. Salary $2500 to $3000. B-50.

FACTORY EXECUTIVE, graduate mechanical engineer, age 39, wishes to connect with progressive concern manufacturing interchangeable parts. Has thorough knowledge and practical experience in scientific-management methods, manufacturing and foundry methods and employment matters. For the last 7 years connected with modern progressive concern as production manager and assistant works manager. Immediately available. B-51.

OPERATING ENGINEER. Associate-member, age 40, with 15 years' experience and 9 years' successful service as chief engineer desires position as chief engineer or superintendent of power with progressive industrial, ore-mining or power company. Good executive. Experience covers steam, electric, producer gas and Diesel engines, and refrigeration. Location immaterial. At present holding responsible position. B-52.

MECHANICAL ENGINEER of 16 years' experience desires position as general superintendent or production supervisor. Has had extensive experience with modern systems of management, the setting of tasks, piece and bonus rates, routing and scheduling of work and storeroom systems. Has acted as superintendent or organization engineer in the metal-working, textile and paper industries. B-53.

ENGINEERING SURVEY

A Review of Engineering Progress and Attainment in Mechanical Engineering and Related Fields, Including a Digest of Current Technical Periodicals and Selected Titles of Engineering Articles

Corps of Engineers of the U. S. Army

THE war threw open to the Corps of Engineers a tremendous task, especially as compared with its former quite limited activities. In fact, as stated by E. J. Mehren, editor of the *Engineering News-Record*, its purchasing activities have increased 2250 per cent within three months. More than fifty engineer regiments had to be equipped, where only three had been equipped before. The organization had to be built up for handling these increased duties and all of this had to be done at top speed and in a businesslike manner.

In the General Engineer Depot purchases are being handled at present at the rate of more than $1,000,000 a day for every day in the year, with all this immense volume of business concentrated in one office. In fact, it is likely that if the war should continue, probably double that amount will be spent in the succeeding fiscal year.

The work of the General Engineer Depot is very far from being one of a routine character. In the first place, a number of specialist engineer units of a novel character have been authorized, with an equipment far more complex than that of the pioneers of prewar time. Service troops are provided for each special engineer regiment.

Even the equipment for pioneer troops, which has been standardized to a certain extent, had to be modified to fit present needs because of the advance in modern methods of warfare, while for the special regiments all of the equipment had to be selected, readopted or designed anew.

Some idea of the variety of purchasing may be gained from the standard detail supplies of the pioneer regiments alone. These cover more than 300 items and range all the way from pencils to wagons.

Quite frequently the Depot has to handle large orders in which speed is an essential element. Thus standard-gage 90-ton locomotives of a certain type were needed. An order for 300 units was placed on July 19 and on August 11 the first engine was delivered and the order called for completion by October 1.

The purchases, with the exception of some of the equipment of pioneer troops, may be roughly classified into three classes, as follows:

First, such equipment as has been standardized commercially and which without change can be used in military service.

Second, such standard commercial equipment as can by slight changes be adopted for military use.

Third, equipment not used for commercial purposes and which must be designed from the ground up.

The policy of the Depot is to buy commercial equipment whenever possible. It happens, however, that modifications become necessary for military reasons. On the other hand, in other instances, the work of the Depot has clearly disclosed a lack of a standard satisfactory even for commercial use. Thus, it was found that there is no standard rating of gasoline engines and the ratings did not mean the same thing to two different manufacturers, and, in addition, almost without exception, the graded rating was too high.

To expedite its work the practice of the Depot has been to confer with the officials of manufacturing companies from whom it is proposed to purchase, and to insist that the higher officials of the companies be in charge of these negotiations. Manufacturers have found it of advantage to bring with them their engineers and shop superintendents. Discussion with these latter frequently disclosed ways and means by which the production could be considerably increased.

The system of inspection and payment has been simplified and made as businesslike as possible. More than 1400 inspectors are either in the direct service of the Depot or are at command, much of the inspection being handled by R. W. Hunt & Co. These inspectors not only pass the material, but accept it. They deliver to the contractor a certificate of inspection which the latter sends to the General Engineer Depot with his invoice, and payment is made immediately.

In this way firms which negotiate for materials and have big labor bills are able to meet their obligations with promptness, an important factor in securing satisfactory bids.

The original article gives a chart indicating the organization of the War Departments General Engineer Depot. It also contains a list of the principal officers in charge of the various sections. The majority of these officers had extensive previous experience, many of them in commercial employment. (*Engineering News-Record,* vol. 80, no. 1, January 3, 1918, pp. 25-29)

Society of Automotive Engineers

The thirteenth meeting of the Society of Automotive Engineers was held on January 9 and 10. The first day was devoted to various committee meetings, and the second to society business, such as election of officers, etc., and professional sessions. Charles F. Kettering was elected president for the coming year.

At the professional sessions three main subjects were discussed: the Liberty airplane engine, the design of the U. S. war truck, and the question of fuel for automotive apparatus.

As regards the Liberty motor, the main paper was presented by Major J. G. Vincent, Mem.Am.Soc.M.E., one of the two men who, according to Secretary Baker's statement, were locked up in a room in the Willard Hotel and told to design the American aviation engine.

The first unit designed was an 8-cylinder engine of about 150 hp., but before that was completed it was decided to provide a 12-cylinder engine giving over 300 hp. At present only the 12-cylinder engines are being turned out and it is not believed that smaller engines will be built during the war.

In the discussion which followed, H. M. Crane called attention to the fact that an engine cannot be copied. As an instance, he cited the Mercedes engine. A number of attempts have been made to copy it, but none of these copies can be compared with the original in efficiency and usefulness.

The Liberty motor is an embodiment of the idea of a small number of parts, simplicity of parts, and compactness, all of which make for light weight and reliability.

There is no reason why the Liberty engine cannot be operated satisfactorily at low speed. It has no unusual valve timing. The exhaust valve opens 52 deg. early and the inlet closes 45 deg. late.

Fuel is fed by pressure, auxiliary tanks being provided for emergencies. The lubricating system is of the pressure type with the double-deck pump and three gears in the top deck.

Two compression ratios are used at present for the Liberty engines. In the navy engines, which have to fly at altitudes of about 5000 ft. or less, the compression ratio is 5 to 1; in the army engines for altitudes of around 10,000 ft. or higher, it is 5.4 to 1, or something under 18 per cent.

The steel cylinders are so arranged that the cooling water can be brought up close to the spark plugs. The compression pressures have not yet been carried extremely high in the Liberty engine, so that spark-plug trouble as ordinarily known in aviation engines has not been experienced.

The design of the Class B military truck engine was discussed in a paper presented by A. F. Milbraith, Mem.Am.Soc. M.E.

It was desired to develop an engine with a torque output of at least 2800 lb.-in. An average of the daily performance of engines built in the past is about 6¼ lb.-in. per cu. in. of piston displacement, which indicated a piston displacement for the engine of about 450 cu. in.

As it was desirable to keep the stroke-bore ratio as high as possible without excessive total weight or overall height, a 6-in. stroke was adopted with a bore of 4¾ in. The normal speed was set at about 1050 r.p.m., giving a piston speed of 1050 ft. per min. The speed of maximum horsepower was predetermined at about 1500 r.p.m.

The paper describes in detail the various features of design. Of particular interest are the inlet and exhaust manifolds. They are both on the right-hand side of engine. A heating chamber is cast integral with the inlet manifold near the center, where the vertical branch from the carburetor joins the horizontal section. This heating fixture is bolted directly to the exhaust manifold at a point where an opening is caused by the latter, so that the hot gases are circulated around the inlet manifold. This forms a hot spot about four of five inches long which helps vaporize the fuel and permits the use of low grades of gasoline.

From tests made it appears that a torque of 7.27 lb.-in. per cu. in. of piston displacement was obtained, while the maximum horsepower would be developed at 1550 r.p.m. (Abstracts of these two papers are made by special courtesy of the Society of Automotive Engineers from advance proofs. The full texts of the papers will appear in an early issue of the *Journal of the Society of Automotive Engineers*.)

New York Automobile Show

The Automobile Show held at Grand Central Palace, January 5 to 12, was, in many respects, one of the most remarkable exhibitions of its kind.

The latter part of the period of preparation for the show passed under conditions of great stress, with the air full of apparently authentic rumors of drastic curtailment of the passenger-car industry.

Fortunately, by the time the show opened its doors to the public the great importance of the American automobiles to the country and the prosecution of the war became clear and the position of industry reasonably assured.

The show did not exhibit any clearly war features of the automobiles and the conditions created by the events of the last year could be observed only indirectly. It is but natural, however, that they should have begun to exert their influence on the design of the cars.

There are two elements, which, if one may judge by the last show, are going to affect the industry most profoundly. The first is the growing tendency toward economy both in the size of the car and the mileage per gallon of fuel. The day of the big, heavy car has not passed, of course, because there will probably always be those who can afford to use it, or conditions where its use may be particularly necessary. But it is significant that practically all of the new cars exhibited at the show are small cars, and that at least one car has already reduced the length of the wheelbase which it employs in its standard model.

Another feature is the tendency toward the better utilization of fuel in the engine. This is achieved in various ways. In the first place there is more extensive application of devices for a better gasification of the fuel, either by the use of jacketed carburetors or by the application of the so-called hot-spot method, that is, superheating a section of the intake manifold by a flow of exhaust gas. Since this latter method has been applied even in the Liberty truck, it may now be considered as current practice.

The other way of better utilization of fuel is by better temperature control of the jacket cooling water. This, as exhibited at the show, is effected in two ways; either by means of a thermostatically controlled valve in the jacket waterline, usually at the outlet to the radiator, or by shutters located in front of the radiator and operated either manually or by means of a thermostat and lever transmission.

Finally, one car has the thermosiphon circulation with a thermostat in the waterline and manually operated shutters in front of the radiator.

Many minor refinements of design have been exhibited, such as an enclosed valve head with the valves operating in a mist of oil; a radiator attachment to condense alcohol used as a preventive of freezing, etc.

Student Units for the Army Authorized at Two Colleges

The War Department has issued the following orders:

By direction of the President and pursuant to the authority invested in him by the provisions of section 41 of the act of Congress approved June 3, 1916, and in response to the application of the Massachusetts Institute of Technology, Cambridge, Mass., the authorities of which have agreed to establish and maintain a two-years' compulsory course of military training as a minimum for its physically fit male students, which course, when entered upon by any student, shall, as regards such student, be a prerequisite for graduation, to allot a minimum of an average of three hours a week per academic year to military training and instruction during the first two academic years and to arrange for five hours per week during the remainder of such student's course, and to use their endeavors to promote and further the objects for which the training corps is organized, there is hereby established in said Massachusetts Institute of Technology, Cambridge, Mass., one Coast Artillery unit, one Signal Corps unit, of the senior division, Reserve Officers' Training Corps.

By direction of the President and pursuant to the authority vested in him by the provisions of section 41 of the act of Congress approved June 3, 1916, and in response to the application of the University of Colorado, Boulder, Colo., the authorities of which have agreed to establish and maintain a two years' compulsory course in military training as a mini-

mum for its physically fit male students, which course when entered upon by any student shall, as regards such student, be a prerequisite for graduation, to allot a minimum of an average of three hours per academic year to military training and instruction during the first two academic years and to arrange for five hours per week during the remainder of such student's course, and to use their endeavors to promote and further the objects for which the training corps is organized, there is hereby established in said University of Colorado, Boulder, Colo., an Infantry unit of the senior division, Reserve Officers' Training Corps. (*Official Bulletin*, January 10, 1918, p. 2)

The Aeronautical Situation

"I have just returned from a visit to the aircraft works in Buffalo, Detroit and Dayton. This was an official visit and so I have seen everything there is to be seen in regard our aircraft program. I can hardly express my feeling of depression. The Liberty motor is coming along splendidly, and it is going to be a great success. But we are not going to have any mechanics competent to repair it. It takes longer to train a mechanic than a pilot. Major Vincent, the man who designed the motor, told me that it would be over a year before we could hope to have mechanics even in small numbers. So far we have made one airplane suitable for use in Europe. The manufacturer assured me that his company could not be on a production program until after the first of July.

"We are having a large number of school planes made, but there are no engines for these. The man who was entrusted with the work has fallen down completely. Even if we were to have the school planes ready we do not have one-tenth the requisite number of teachers, and cannot hope to get them for six months.

"It is very hard to place one's finger on the man or committee responsible for this condition. As far as I could see, the evil is a fundamental one." (From a letter by Professor Joseph S. Ames in the *Atlantic Monthly*, vol. 121, no. 1, January 1918, Contributor's Column)

Rules for Enlistment in Aviation Section of Men of Draft Age

The Aviation Section of the Signal Corps authorizes the following statement to clear up any misunderstanding which may exist as to the enlistment of men in or under the draft age on account of the recent ruling discontinuing voluntary enlistment as a general practice:

Fliers and balloonists may enlist as heretofore upon passing the examination at the nearest aviation examining board. Their relationship to the draft and to the draft board is seen to by the examining board. They themselves are ordered into active service as soon as possible and hold the status of privates, first class, Signal Enlisted Reserve Corps, with a salary of $100 a month, 60 cents daily allowance for food, and quarters provided by the Government, until their commissions are issued or they are discharged.

Non-flying officers of draft age or below are not now being accepted for service, except a limited number of graduates of leading recognized engineering colleges or others who can qualify as expert engineers; others may, if they wish, have their names placed on file at an examining board.

Aerial observers are not now being accepted, whether of draft age or not.

Enlisted men within the draft age may now no longer volunteer at a recruiting office, but may be inducted voluntarily into service by their local board if they are physically fit, sufficiently skilled, and not required to fill the current draft quota. They will be sent to Camp Kelly, Tex., for distribution into trades, training and formation of squadrons, with ranks and salaries running from $30 a month as private to $81 a month as master signal electrician, food and quarters provided by the Government. (*Official Bulletin*, December 27, 1917, p. 16)

Flotation of Ships

The possibilities of insuring the flotation of a large ship after severe damage were discussed before the Institute of Marine Engineers by Charles V. A. Eley, who in particular dealt with the system he himself has devised.

This system combines direct pumping with central means for indicating the position and amount of the damages for operating the pumps, and for leveling the water in the ship in order to preserve a level keel. Collision mats of a special character may also be used.

In connection with these arrangements some of the ship engineers would be trained to act as "salvage engineers," who would go to their stations when the vessel was in trouble or in a danger zone in the same way as a gunner would go to his station. The station would be a small compartment, say, 12 ft. to 15 ft. long and 6 ft. or 7 ft. wide, in the most invulnerable part of the ship. On one of the longer sides, about 6 ft. above the deck, a flat sentinel model of the ship would be placed with slides to operate vertically as indicators to show at a glance if water were building up in any compartment and at what rate. Below each compartment of the model would be placed the means for starting the pumps fitted in each compartment. On the deck, close to the side of the compartment containing the model, there would be a system of levers, almost like the levers in a railway signal box, one for each compartment of the ship, and these levers would control the opening and closing of the valves for leveling the water in the ship, preferably through the double bottom where such exists. Then supposing the ship is damaged at, say, the third compartment from the stern, the indication of the model will show that the water is rising in that compartment, and the salvage engineer will start the pumps on it.

If he sees these are not sufficient to deal with the water entering the ship he will pull over the lever at the same position (No. 3) and let the water travel throughout the length of the ship, and supposing there are twenty compartments, will pull over No. 18 lever and start the pumps in No. 18 compartment. If he finds the water to be still gaining he can pull over levers Nos. 9 and 17 and start the pumps in those compartments, and so on until the water is being pumped out faster than it enters. The ship's carpenter and crew could put into position specially constructed collision mats, or make good inside of the ship, or do both, as by keeping the vessel buoyant by pumping, the inside of the damaged compartment would be opened for purposes of inspection or to make good the damage temporarily.

As a rule, the auxiliary pumps on a ship are not sufficient to deal with the water inflowing through collision or torpedo, but would require to be supplemented with a complete set of pumps capable of being started together and of utilizing the whole, or as much as might be necessary, of the forces existing in the ship for purposes of propulsion to expel water. The author thought that the involute centrifugal single-stage pump

would be the best for the work, though in certain cases the expulsion form of steam pump or even steam-jet pumps might be considered; and in the remainder of his paper he set forth various calculations as to the installation that would be required in the case of a large vessel. (Philadelphia *Public Ledger*, December 26, 1917, p. 13.)

Patent-Reform Prospects

The Patent Office Society is permitted to announce that a composite committee has been created upon request by the National Research Council to make a preliminary study among the problems of the United States Patent Office and its service to science and the useful arts. This action is understood to be in conformity with the wishes of Commissioner of Patents, J. T. Newton, and Secretary of the Interior, Franklin K. Lane.

According to the resolutions adopted by the Patent Office Society, this is the proper time for taking preliminary steps about the establishment of the institute, such as was proposed some time ago by George Sarton and others, for the history of science, a proposal which is supported also by the Washington Academy of Science.

The Patent Office corps feels that the time is at hand when the Patent Office must enter upon either a period of very rapid decline, or else upon a period of rehabilitation and expansion.

The special committee asks some very pertinent questions. For example, can all who are employed in the work of examination be in any way further encouraged and aided to become specialists in one or the other of the branches of applied science, rather than mere rule parrots and picture matchers? This, apparently, implies a desire on the part of the examiners to be placed in a position where they could investigate new applications on the basis of a full knowledge of the previous art, rather than, as is a fact to a certain extent now, be guided mostly by Patent Office indexes.

Another question is whether the rules against dilatory prosecution of applications made by Commissioner Ewing be rendered secure for the future, in order to create a diligent rather than dilatory prosecution.

Before Commissioner Ewing's time the rules were such that applications could be kept alive for many years. Thus, the famous Selden patent was kept alive for nearly twenty years, which was easy since the applicant had two years for each amendment, and, for example, Selden used to file his amendments, sometimes of a trivial nature, just a few days before the lapse of the two years. Commissioner Ewing changed all this, reduced the time for filing amendments, and gave the Patent Office means of enforcing a rapid prosecution of an application.

The Patent Office Society requests that sugestions on patent reform be forwarded at once to Dr. Wm. F. Durand, (Mem. Am.Soc.M.E.), National Research Council, Washington, D. C. It is not expected that patent reform can claim primary consideration during the continuance of the work, but it is felt that the time is ripe for, at least, a study of conditions. (*Science*, New Series, vol. 46, no. 1200, December 28, 1917, pp. 629-631)

British Electrical Power Plan to Save Coal

The big electrical power-supply scheme, formulated by the coal-conservation sub-committees of the Ministry of Reconstruction, is the latest item to be made public of the Ministry's important proposals for the future. The scheme has been issued in an interesting report by the sub-committee to the Ministry so that public opinion may have an opportunity to form itself.

How much of the scheme will be adopted remains to be seen, but Dr. Addison, in a preface, draws attention to the important issues, affecting municipalities and public bodies, raised in the report and states that the Government will explore all the sub-committee's proposals before proposing any action to Parliament.

The scheme, it is expected, would save 55,000,000 tons out of the 80,000,000 tons used in the United Kingdom for producing power.

The cost of this 80,000,000 tons at the pit head is roughly £40,000,000, and of this £27,000,000 could be saved. With the saving of by-products now wasted by burning coal in open grates and boiler furnaces, a national economy of £100,000,000 could be effected. The coal now used would if used economically, it is said, produce at least three times the present amount of power.

Increased use of electric power, it is pointed out, is the most economical way of obtaining power from coal, is the best way to increase the net output per head, with the resulting prosperity of the workers.

The committee makes proposals for getting the fullest value of by-products and for generating electricity in subsidiary plants wherever there is surplus gas or waste heat as at furnaces and coke ovens. Similarly waste coal left at pits could be used on the spot.

The committee point out that the Northeast Coast district is already served by a group of power companies from one interconnected electric system. Despite the smaller population and disadvantages for electrical supply as compared with Lancashire, which has a multiplicity of electrical undertakings, the price per unit in this district is from one-half to one-quarter the price per unit in Lancashire, while the use of electric power per head is three times as great.

The scheme in the Northeast Coast district has meant a saving of coal, reduction of smoke, greater traffic facilities through the adoption of electric traction than in any other district of similar size, the establishment of new industries in the district, and the practical elimination of the burning of coal for power, apart from the electrical power company's consumption, the railways and some collieries.

Among the advantages the committee foresees are the elimination of factory chimneys and the smoke nuisance, electrification of railways even for goods trains, electric light for the poorest classes, and so forth. The development of a technically sound system of electricity supply, the committee states, is essentially one with the problem of the industrial development of the country. (*Christian Science Monitor*, January 2, 1918, p. 1)

May Admit Women to U. of P. in Month

To offset the loss of more than 2000 students who have enlisted in various branches of the Government service, all departments of the University of Pennsylvania will be declared open to women, beginning with the second term in February, according to an unofficial statement made yesterday by a university official.

One of the reasons and perhaps the chief one for hurrying the general admission of women is the \$250,000 deficit the university faces on account of its reduced enrollment. During the Christmas holidays scores of students have gone into the

service and will not reopen their books. Many of these men would have graduated this year, but a large number are below the draft age and could have remained at school for a year or two. Prior to the holidays these students were advised that it was their duty to remain in college until they were called, but virtually all paid no heed to the admonitions. In one department alone—the Wharton School—fifty-seven students enlisted within ten days. (Philadelphia *Public Ledger*, January 3, 1918, p. 7)

Oil Experimental Station at Bartlesville, Okla.

Secretary of the Interior Lane has designated Bartlesville, Okla., as the location of the new experimental station of the Bureau of Mines for the investigation of problems relating to petroleum and natural-gas industries. The station is one of the three new experimental stations for the establishment of which the sum of $75,000 was appropriated by the last Congress. The two other stations have been located at Minneapolis, Minn., for the study of iron and manganese problems, and at Columbus, Ohio, for research connected with ceramic and clayworking industries.

The technical staff of the new experimental station will study various problems having practical commercial application to the petroleum and natural-gas industries, including questions of productions, transportation, storage and refining of petroleum and various problems connected with the technology of natural gas.

One of the greatest needs of the petroleum industry has been the coördination of scientific research with the practical side of industry, for compared with other mineral industries it has been singularly backward in this respect. The station is aimed to act as an intermediary between the facts evolved by scientific investigations and the needs of the oil industries. That is, men will be employed who will be able to gather scientific data and find out how they may be applied to the practical needs of the industry. (*Official Bulletin*, January 9, 1918, p. 10)

U. S. BUREAU OF STANDARDS

A NEW type of rope-measuring device or rope meter has been thoroughly investigated by the Bureau, using different sizes of ropes in the range of capacity of the instrument and different methods and tensions of pulling the rope through the meter. Suggestions for the improvement of the meter were made to the manufacturer in the Bureau's report.

Space Occupied per Ton of Various Commodities. In connection with the shipping of Government supplies to the front, the Bureau is now engaged in compiling data as to the cubic contents per ton of practically all such commodities. The purpose is to determine the most effective distribution of freight in relation to the available facilities. The sources from which such data are to be obtained have been ascertained and the work of collecting this information is in active progress.

Measurement of Metal Hardness. Data have been gathered by the Bureau as to the hardness numerals obtained with the "Brinell meter" and the "universal Brinell machine." The relative agreement of hardness numerals obtained from depth and diameter measurements is also being determined. The object is to ascertain the relative precision of these instruments, standardize the practice, and facilitate the general tests for hardness. The work is nearly completed.

Radium Luminous Materials. The use of self-luminous materials for the figures on the dials of measuring instruments for night use has called for the careful measurement of the relative brightness of such materials. Methods of measurements have been developed at the Bureau and a standard procedure has been formulated for routine work. The Bureau is investigating possible methods of avoiding the large loss of brightness involved in the present methods of applying luminous materials, with excellent prospect that the loss can be greatly reduced.

Standards of Gas Service. Two important problems have arisen in connection with standards for gas service. Some companies cannot maintain quality at the prevailing price without a loss. The second problem is the making of arrangements to secure the supply of toluol needed for military purposes and which can be most readily obtained from illuminating gas. The two problems have become confused and the Bureau of Standards is endeavoring to consider each separately on its merits. The War Department has been given assistance on the technical aspects of the latter subject, and an article on toluol recovery and standards of gas quality has been sent to the trade journals to secure the needed publicity. As illustrating the changed economic conditions in the gas industry, the Bureau has prepared a statement of the technical phases of the gas situation in the District of Columbia for the use and guidance of the Public Utilities Commission of the District.

Metals. New data have been obtained on light alloys and four reports have been issued by the Bureau on the several phases of its work in this field. New automatic recording apparatus has been designed for taking cooling curves and improved methods of manipulation were devised and tested out in practice. The new apparatus gives more satisfactory results, particularly at the lower temperature ranges, and the characteristics of the curves are more sharply defined.

International Aircraft Standards. The Bureau continues to take an active part in formulating the new International Aircraft Standards. During the past month 14 of these specifications were completed and published.

High-Purity Platinum. In the Bureau's investigation of platinum purity recent tests have developed the interesting fact that the highest possible purity attained hitherto only by a German firm can now be equaled by an American refiner of platinum. This will be of much interest to those concerned with the technical use of highly pure platinum, the supply of which was cut off very shortly after the beginning of the war.

Fire Resistance. Progress is being made in the Bureau's investigation of the fire-resisting properties of reinforced-concrete columns. A new column was made up to test out the simple expedient of holding the protective covering in place under fire conditions. The tiewires connecting the vertical rods with the hooping were cut and free ends allowed to project outside of the reinforcement. These are intended to service as anchorages or ties to prevent slabs of the protective covering from falling away from the column exposing the load-bearing portion to the heat as soon as the covering breaks by reason of the expansion.

Safety for the Household. The safety of the home is the subject of a new pamphlet just issued by the National Bureau of Standards. An interesting account of household hazards is given. The topics are discussed clearly in a manner which

would afford a basis for popular education in "Safety First." The dangers from electricity, gas, fire, lightning, household chemicals, and the other common causes of accident are recited, and many actual cases are described. The purpose is to aid in removing needless risk and fear, and to develop intelligent caution where the hazard cannot be entirely avoided.

The hazards of the home have increased in modern times from the service of gas and electricity and the use of such dangerous articles as matches, volatile oils, poisons, and the like. The use of energy in the home necessarily involves some risk, which intelligent planning and care will reduce to a minimum.

Caution alone is not enough, since many of the dangers are not even suspected. The nature of such unknown hazards must be made plain. The circular emphasizes the seriousness of some of the risks not generally known, gives simple cautions, and aims to guide the formation of habits of carefulness. The circular also suggests effective home equipment to minimize the risks involved, and aims to encourage public measures to provide safety for the household and community.

It is intended, not to increase fear of accident, but rather to remove the causes and the need for alarm. The sense of safety to be gained by observing these cautions would alone justify the careful study of this new circular. This circular completes the series of three popular household circulars which deal with measurements, materials, and safety. These form a valuable addition by the Bureau of Standards to the literature on household management.

The appalling loss of life from avoidable causes and injury to person and property make the pamphlet especially timely. It is believed that thousands of human lives could be saved and accidents reduced to a minimum if the precautions suggested are followed.

Leather Research. Results have been compiled covering laboratory tests and actual service tests of a special tannage of sole leather. Investigation has been conducted to study the wearing qualities of sole leather and of composition soles. The experiments comprise accelerated wearing tests on a machine provided for that purpose and actual service tests conducted by postmen and other Government employees. Similar service tests will be made on shoes worn by soldiers. A study of the water absorption of different grades of sole leather is in progress.

This Month's Abstracts

The simplest—apparently—phenomena of nature may yield results of great importance, if thoroughly and skillfully analyzed. The boiling of water in a metal cup over a gas flame is an everyday experience in practically every household, and what happens there has been supposed to be well known. As a matter of fact, however, Dr. Carl Hering's investigation reported in the section Steam Engineering shows that by changing the shape of the bottom of the cup in an appropriate way, an evaporation many times greater than that obtained from the flat bottomed cup may be secured.

In the section Coolers is described the Heenan method for cooling the jacket water from stationary gas engines in use in India. It is of the open-film type of apparently simple construction.

In the section Engineering Materials are reported several investigations on binary alloys and also two investigations on properties of steel at high temperatures. In the investigation on the thermal expansion Kotaro Honda has determined the relation between the coefficient of expansion of various steels and the contents of impurities, also the elongation curves in the various stages of transformation. The data obtained from this investigation give an insight into the causes of cracking of steel in cooling.

An investigation on the effect of the presence of a small amount of copper in medium-carbon steel by Carle R. Hayward and Arch. B. Johnston has shown that steel containing 0.860 per cent copper is, in practically every respect, superior to steel containing 0.30 per cent copper.

In this connection the article by F. H. Mason in *The Mining and Scientific Press* becomes of considerable interest, in that it discusses the direct production of steel from Sudbury ores. There one of the difficulties lay in the presence of about $1\frac{1}{4}$ per cent copper, which it was believed would make the steel hot-short. F. H. Mason shows, however, that the presence of nearly $3\frac{1}{2}$ per cent of nickel neutralizes this deleterious effect of copper.

In the section Engineering Materials is found an article on the production of pig iron from scrap steel, the so-called synthetic pig iron. It is one of the outgrowths of the abnormal war conditions in the raw material market, but an important one at the present moment.

A double-pass recuperative furnace is described in the section Furnaces.

A mathematical investigation of the flow of water in siphons is abstracted in the section Hydraulics from a paper presented before the Institution of Mining Engineers (Great Britain).

In the section Internal-Combustion Engineering, Cole Newman describes a modified-cycle Diesel engine with compound expansion, which he believes might be suitable for use on motor vehicles. In the same section will be found a discussion of the question of uniformity of multi-cylinder engines in its bearing on engines having no flywheels. The Howard cuff-valve engine is described in the same section.

In the section Lubrication will be found a description of the Michell automatic lubricating gear, the purpose of which is to lubricate during starting and stopping.

The calibration of anemometers is discussed by A. H. Anderson, Mem.Am.Soc.M.E., who claims that the short-arm method of calibrating anemometers may give quite erroneous results.

Formulæ to be used in pin measurement of spur gears are given by Reginald Trautschold in an article abstracted from *Machinery.*

In the section Mechanics, Wilhelm A. Schmidt, Mem.Am. Soc.M.E., discusses further the relation of press stroke to the life of a die, and shows that the whole question in the final count comes down to the number of strokes at the same cutting velocity of the punch within a given time. It is natural that if the same cutting velocity can be obtained with the shorter stroke that was formerly obtained with the longer stroke, the number of useful strokes per unit of time would be greater in the first case.

Tests made by the Research Department of the National Tube Company have shown that in pipe joints the round thread is superior to the Briggs thread in various regards.

In the section Munitions will be found a bibliography on the French 75-mm. cannon, the famous "soixante-quinze," prepared by the Library of the United Engineering Society.

In the section Steam Engineering is reproduced a brief mathematical investigation by Gerald Stoney on the divergence of steam nozzles, originally appearing in *Engineering.*

Heat transfer in tubes by W. Nusselt is indirectly abstracted from the *Journal of the Society of German Engineers,* while from the *Proceedings of the Royal Society* is abstracted an interesting investigation on the specific heat of water by W. R. Bousfield.

REVIEW OF ENGINEERING PERIODICALS

SUBJECTS OF THIS MONTH'S ABSTRACTS

For Articles on Subjects Relating to the War, see Aeronautics, Engineering Materials, Machine Shop, Munitions, Varia.

Aeronautics

Special Spark Plugs Needed for Airplane Engines. *Automotive Industries*, vol. 38, no. 1, Jan. 3, 1918, pp. 29-32, 4 figs. 1. Unusual Insulating Materials Seldom Withstand Heat; 2. Electrode Must Be Specially Cooled; 3. Oil Must Not Reach Insulation or Must Be Burned; 4. Plug Must Have Good Mechanical Strength.

Overhauling the Gnome Airplane Engine. *American Machinist*, vol. 48, no. 1, January 3, 1918, pp. 9-15, 16 figs.

British Aviation Engine Inspection, Lieut.-Col. R. K. Bagnall-Wild. *Automotive Industries*, vol. 38, no. 2, January 10, 1918, pp. 125-130, 2 figs., 3 charts. Part 1: Chart scheme of couple system in use; best methods of employing women in work; routine for rejection by government men; plan of using approved firms is favored; advantages of inspection to companies. Pt. 2 to follow.

Some Notes on Recent German Aeroplanes. *The Engineer*, vol. 124, no. 3233, December 14, 1917, pp. 516-518, 6 figs.

The Armament of Aeroplanes. *Engineering*, vol. 104, no. 2708, November 23, 1917, pp. 544-546, 24 figs.

Aeroplani Velocissimi. *Revista Marittima*, Anno 50, no. 9, September 1917, pp. 355-366, 2 figs., 4 charts, 2 tables. Gives formulæ and curves showing the relation of aeroplane displacement to speed, radius of action to speed, engine power to speed; also a table for various types of machines giving weight of machine, weight of power plant, output, and radius of action. An abstract of this article will be given in an early issue.

On the Maximum Flight Value of Aeroplanes, Umberto Nobile. *Aeronautics*, vol. 13, no. 216 (New Series), December 5, 1917, pp. 434-436, 2 charts.

Air Engineering

The Temperature of Evaporation, Its Practical Application to Air Conditioning and to the Drying and Conditioning of Materials, W. H. Carrier. *Journal of the American Society of Heating and Ventilating Engineers*, vol. 24, no. 2, January 1918, pp. 227-248, 6 figs.

Dust: Its Universality, Elimination and Conservation, E. R. Knowles. *Journal of the American Society of Heating and Ventilating Engineers*, vol. 24, no. 2, January 1918, pp. 285-327, 44 figs.

Air Machinery

Gasoline-Driven Air Compressor. Fig. 1 shows a section through a gasoline-driven air compressor, built by the Chicago Pneumatic Tool Company. It is of the horizontal, straight-line, single-stage, double-flywheel, enclosed-frame type. The power and air cylinders are connected in tandem.

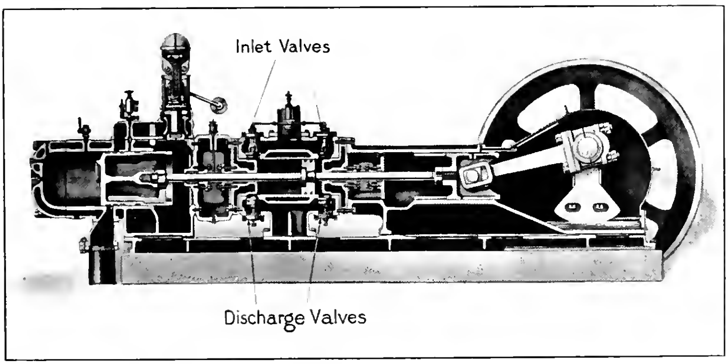

Fig. 1 Gasoline-Driven Air Compressor

The power cylinder is operated on the two-stroke cycle with low compression and high-tension electric ignition, a pressure governor regulating the amount of gasoline that is admitted to the cylinder.

The crosshead is of the single-piece box pattern without adjustable shoes, and it overtravels the guide nearly one-half its length at each end of its stroke; thus bringing the longitudinal wear on the guide on an even straight line throughout its length.

A combined speed and pressure governor is used in conjunction with the differential unloader on the gas-driven compressor. Together these automatically limit the speed of the machine, maintain a practically constant air pressure at all times, and reduce the load to a minimum when there is no demand for air. The unloader controls the air supply by permitting the opening to the air inlet valves and allowing the air in the cylinder to return to the atmosphere whenever the pressure in the receiver exceeds the predetermined amount. (*Power*, vol. 46, no. 25, December 18, 1917, p. 83, 1 fig., *d*)

Coolers

MECHANICAL WATER COOLING ON THE HEENAN PRINCIPLE. The Heenan cooler was primarily designed for use with stationary internal-combustion engines, but may be used for other purposes. It consists of cylinders built up of galvanized sheeting wound into the form of a spiral with air spaces between each convolution. The sheeting forms a large cooling surface within a small space. The cylinders are caused to revolve slowly in a covered trough containing the water to be cooled, and in revolving they take up the thin film of water which wets both sides of the sheet. A fan fixed at the end of the upper part of the cooler casing causes air to be blown through the annular spaces of the cylinder. This cools the film of water on the sheets; a considerable additional cooling effect is obtained by the partial evaporation of the water film.

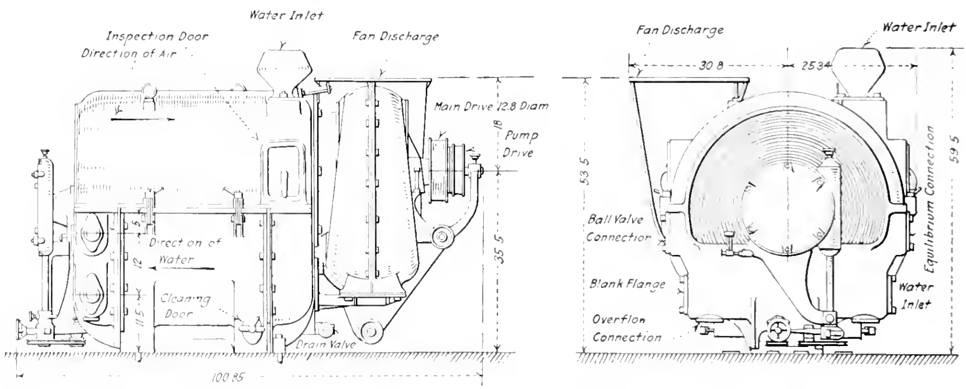

FIG. 2 HEENAN WATER COOLER FOR 200-B.HP. ENGINE WORKING UNDER TROPICAL CONDITIONS

The construction of the cooler is shown in Fig. 2. It is stated that such a cooler for a 100-b.hp. engine working in a tropical temperature requires a floor space of about 6.5 ft. by 5.5 ft. with 3.5 ft. headroom, while the natural-draft cooling tower for the same capacity would be about 7 ft. square and 15 ft. high. The power required to operate the cooler is said to amount to less than 1 per cent of the engine power for large sizes.

It is said that there are a large number of these coolers installed in India. One cooler to handle 30,000 cu. ft. of air per min. is working at the Calcutta Electric Supply Company's new power station at Cossipore in connection with the large turbo-alternator. (*Indian and Eastern Engineering*, New Series, vol. 41, no. 3, September 1917, pp. 85-86, 2 figs., *d*)

Engineering Materials

THE THERMAL EXPANSION OF DIFFERENT KINDS OF STEEL AT HIGH TEMPERATURES, Kotaro Honda. Data of an investigation on the expansion of a Swedish iron, ordinary steel, and high-speed tool steel at various high temperatures.

To measure the expansion Chevenard's method was used and the measurements were made in a vacuum to avoid the oxidation of the specimens.

In particular, the relation has been determined between the coefficient of expansion of various steels and their content of impurities, especially manganese. In the case of Swedish steel the A_1 transformation is not observable in the elongation curve at all. In the range of A_2 transformation abnormal contraction is scarcely observable, but in the range of A_3 transformation a gradual contraction by heating and a gradual elongation by cooling are noticed. But in steel with 0.14 per cent carbon the abnormal change of length begins to appear in the A_1 transformation, clearly distinguishable from that during the A_3 transformation. This abnormal change of length in the A_1 range is more conspicuous in the 0.18 per cent carbon steel, while in the steels of 0.31 per cent and 0.44 per cent carbon, the temperature of the A_3 transformation noticeably decreases and the abnormal changes of length corresponding to the two transformations, A_1 and A_3, partially overlap each other.

It is also interesting to observe that manganese, even when present in a very small quantity in steels, affects their coefficients of expansion to quite a large extent.

The various high-speed steels show elongation curves rather similar to each other. They also show the abnormal contraction in the vicinity of 850 deg., probably due to the A_3 transformation. Their coefficient of expansion increases with temperature.

The following remark is made by the writer:

Since for high-speed carbon steels the abnormal elongation or contraction due to the A_1 and A_3 transformations takes

place abruptly, it is possible that in the case when the temperature of a large specimen in the range of 700 deg. cent. is not uniform throughout the specimen, an internal strain and therefore an enormous stress will be developed during heating and cooling. During heating the inner portion is cooler than the outer portion, so that at about 700 deg. the outer portion contracts while the inner portion has not yet begun to contract, and therefore the outer portion exerts an enormous compression inward. During cooling the contrary is the case.

Besides the fact that the coefficients of expansion of steels investigated in the range of temperatures below the A_1 point increase rapidly with the temperature, it has also been found that the coefficient of expansion-temperature curves are slightly concave toward the axis of temperature, with the exception of some tungsten steels, for which the contrary is the case. (*The Science Reports of the Tohoku Imperial University*, Sandai, Japan, First Series, vol. 6, no. 4, pp. 203-212 and 6 pages of plates, *e*)

The Effect of the Presence of a Small Amount of Copper in Medium-Carbon Steel, Carle R. Hayward and Arch. B. Johnston. Data of an investigation undertaken in order to obtain additional data on the mechanical properties of medium-carbon steel containing small quantities of copper. The discussion is introduced by brief references to previous investigations, which, by the way, agree that copper increases the tensile strength, but disagree in regard to the ductility, and touch only in a slight degree upon the question of resistance to shock.

In the present investigation two types of steel were tested: one containing 0.30 per cent copper, 0.012 per cent phosphorus, and 0.860 per cent copper, and the other 0.365 per cent carbon, 0.053 per cent phosphorus and 0.030 per cent copper. As regards the difference in phosphorus, the writers expressed the belief that it is probable that the effect of phosphorus is neutralized by this slight difference in carbon.

The bars tested have been subjected to various kinds of heat treatment. The samples were submitted to tensile tests, shock tests, Brinell and scleroscopic hardness tests, and a microscopic examination. The results are presented in the form of tables and curves, and of the latter Fig. 3 is here reproduced.

These tests have shown that in regard to tensile strength high-copper steel has a decided superiority. The yield point and ultimate strength are in every case higher, while the ductility is practically the same. The hardness tests by both methods show a high-copper steel to be harder than the low-copper, while the Charpy shock tests show a high-copper steel also superior to the low-copper. In all, the tests have confirmed the previous statement made by Stead that the behavior of copper steel resembles that of nickel steel. Microscopic investigation revealed that for the same heat treatment the high-copper steel was finer grained than the low-copper. The quenched and drawn specimens of high-copper steel were also found to be slightly more martensitic. (*Bulletin of the American Institute of Mining Engineers*, no. 133, January 1918, pp. 159-167, 1 fig., *e*)

Pig Iron from Scrap Steel. This is what is known as synthetic pig iron, and is a material that has now become a commercial product.

The production of munitions on an unprecedented scale has created a vast amount of scrap steel in the shape of shavings, ends, and rejected material. This, together with the general shortage of raw materials, has made it necessary to find a convenient method of utilization.

At first glance it may appear that converting steel into pig iron is a rather illogical method of procedure. Actually, however, especially in Europe, it has been found to answer the particular purpose of producing a uniform material from a mass of scrap of varying carbon content.

The new process is now being applied commercially in the United States at the Sweetzer-Bainbridge Metal Alloy Corporation at Watervliet, New York, where two 5-ton Ludlum electric furnaces are used with the daily output of about 50 tons per day.

The process is not really new but is quite simple, although the precise procedure is not published. The process is now basic. Ordinary scrap steel of any grade is introduced into the furnace cold, is melted and, if necessary, refined. After the desired refinement is reached the slag is removed. The necessary amounts of ferrosilicon and ferromanganese are added to bring the iron to the composition desired, and then the carbon is added in the form of fine coke, which is easily absorbed by the hot metal.

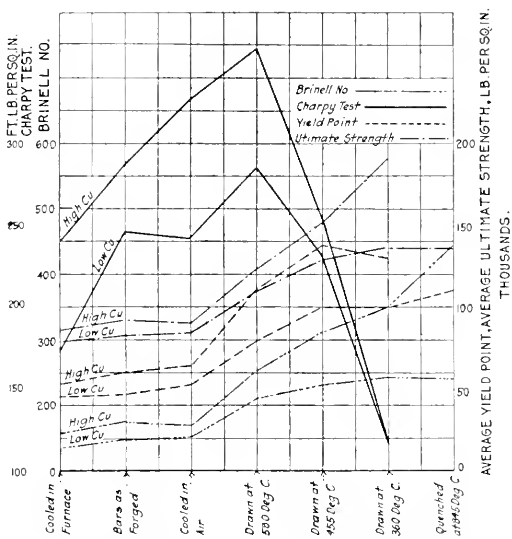

Fig. 3 Physical Properties of Copper-Bearing Medium-Carbon Steel

The regulation of the temperature and composition is quite simple, and a range from high-grade low-phosphorus iron and wash metal down to the high-phosphorus foundry and other irons is possible. The graphitic carbon content is regulated by the introduction of varying percentages of silicon. A knowledge of the composition of the scrap charged into the furnace permits to regulate quite closely the phosphorus and sulphur contents.

The pig iron is reported to be very tough and strong. As to cast iron in the form of castings, the experience of the Ludlum Steel Co. is cited. Cast-iron wobblers, for use in the company's rolling mill, which were purchased in the open market, were breaking at the rate of 10 to 12 per day. Wobblers from iron made in the electric furnace have been in use for two or three months without a case of breakage. The

company also made breaking boxes on the mill of electric cast iron. These should break easily when performing their normal function, but when made of this iron they were found to be entirely too tough, and their section had to be reduced considerably. It is believed that some explanation for these qualities may be found in the crystalline structure of the iron, as well as in its greater purity compared with cupola iron, because in the electric process, contrary to cupola practice, the sulphur decreases with each remelting. In making steel castings, the conversion loss is put at 5 per cent. The cost of production is one of the vital points. So long as low-phosphorus pig iron is selling at its present war price there can be no question as to the liberal profits obtainable. Whether in normal times such a method of making this grade or any other grade of pig iron or castings is economically possible depends on several factors. First among these are the consumption of electricity and the grade of scrap used. (*Mining and Scientific Press*, vol. 115, no. 23, December 29, 1917, pp. 936-938, 2 figs., *dp*)

Memoirs of the College of Science, Kyoto Imperial University, vol. 2, no. 4, July 1917, pp. 227-254, 19 figs. A series of metallographic investigations on the binary alloys aluminum-selenium, zinc-selenium, cadmium-selenium, antimony-selenium and aluminum-tellurium.

Nickel-Copper Steel Direct from Sudbury Ores, F. H. Mason. *Mining and Scientific Press*, vol. 116, no. 2, January 12, 1918, pp. 57-58. Discusses methods used. The process was formerly considered impossible as the material produced would contain more than 0.75 per cent copper and therefore might be expected to be hot-short. It has been found, however, that a slightly larger per cent of copper is harmless in the presence of a sufficiently large amount of nickel in the same steel.

Tungsten and High-Speed Steel. *Engineering*, vol. 104, no. 2709, November 30, 1917, pp. 567-568. Description of processes used in the production of tungsten and especially high-speed tool steel.

On the Thermal and Electrical Conductivities of Carbon Steels at High Temperatures, Kotaro Honda and Takeo Simidu. The *Science Reports* of the Tohoku Imperial University, First Series, vol. 6, no. 4, November 1917, pp. 219-233, 4 plates. Data of tests carried out to determine the thermal conductivity of carbon steels at high temperatures as well as the electric resistances. As regards thermal conductivities it was found in Swedish iron-steel and iron that conductivity decreases at first slowly and then somewhat rapidly as the temperature is increased. Above the A_2 point it slightly increases in a linear relation to the temperature, a change of conductivity by temperature being apparently quite parallel with that of magnetization. Tests were carried out for temperatures up to 900 deg. cent. and it was found that for pure iron and nickel, and probably for all pure metals, Lorenz's law is exactly satisfied. Hence, for these metals the value of thermal conductivity at high temperature may be estimated from that of ordinary temperatures provided only the electrical resistance at the high temperature is known.

Fuels

Peanut Oil as Fuel for Motorships. The large motorship *France* has successfully used peanut oil as fuel under ordinary ocean-going conditions, which confirms the former claim that Diesel-motor-driven vessels no longer need be dependent upon the supply of mineral oils.

Hitherto vegetable oils have been too expensive and insufficiently distributed to be considered as fuel for merchant ships, but the successful use of peanut oil may bring about a change in this view.

Southern Europe can obtain her supply of peanuts from northwestern Africa. In America there is also a large supply of peanuts. In fact, the Interstate Cotton Seed Crushery Association down South expects a peanut crop this season of a hundred million bushels. However, with the present price of American peanut oil at about 18 cents per lb., or \$57 per bbl., it cannot be economically used for Diesel engines in this country. (*Motorship*, vol. 3, no. 1, January 1918, p. 6)

Alcohol as a Source of Power, W. T. Rowe. *The Engineer*, vol. 124, no. 3231, November 30, 1917, pp. 471-472.

Fuel Saving Suggestions, Charles H. Bromley. *Power*, vol. 46, no. 24, December 11, 1917, pp. 786-789, 1 fig., 2 tables. The writer discusses some of the sources of appreciable loss of fuel when used under steam boilers and means for the elimination of such waste. He describes a recommended style of boiler setting for soft coal and gives complete specifications for this improved type of horizontal tubular boiler. A number of practical suggestions are included. Scraper conveyors, it is stated, are limited to about 300 ft. length. The relative advantages of bucket and bale conveyors are considered.

Blue Water Gas Used for Metal Melting in Great Britain. *American Gas Engineering Journal*, vol. 107, no. 26 (whole no. 3121), December 29, 1917, pp. 588-593.

Double-Pass Recuperative Furnaces. Description of a type of furnace successfully used in Europe.

Notwithstanding certain known advantages in the operation of recuperative furnaces, they have not yet displaced the regenerative furnace, which is mainly due to the inability of the recuperative to withstand temperatures between 1300 and 1500 deg. fahr. for any length of time without undergoing repairs. This applies mainly, however, to the recuperative furnaces of the usual type. In Europe several recuperative furnaces are in successful operation and are of a construction different from those usually employed in this country. They are constructed of hollow-brick blocks, which are built with a male flange on one end and a female flange on the other, with walls $1\frac{1}{8}$ in. thick. When several rows of blocks are placed adjacent they form flues through which the products of combustion pass. Other courses are mounted on top of and parallel to the first row of blocks. Traverse flues are formed between the upper and lower surfaces of these blocks, and it is through these flues that the secondary air is heated before mixing with gas.

The heating furnace is placed on top of the recuperator. The gas enters the lower combustion chamber of the recuperator and flows to the rear, where it mixes with preheated secondary air. This secondary air is heated by passing through ducts which are formed by the collars on the channel blocks when placed one upon the other. The temperature of the air is further increased by passing through another series of ducts, which discharge into a central chamber from which the air is directed to the combustion chamber. (*Iron Trade Review*, vol. 41, no. 24, December 13, 1917, pp. 1277-1278, 2 figs., *d*)

Hoisting and Conveying

Operation and Maintenance of Elevators—Winding-Drum Machines, R. H. Whitehead. *Power*, vol. 47, no. 2, January 8, 1918, pp. 40-43, 5 figs.

Selection of Coal and Ash Conveyors, H. E. Birch. *Power*, vol. 47, no. 3, January 15, 1918, pp. 82-86, 10 figs. The writer believes that four items control the selection of coal- and ash-handling equipment: cost of operation, maintenance, interest on the investment, and adaptability. From his point of view roller flight conveyors are considered desirable.

Hydraulics

Automatic Hydroelectric Plant. Description of a hydroelectric plant which is automatic in all its operations. The plant is so arranged that a rise of water level causes the proper number of generators to start to utilize water most economically. It belongs to the Iowa Railway & Light Co., and is located on the Cedar River.

This plant, which will have an ultimate capacity of 2000 kw., operates in parallel with an extensive transmission system. In the hydroelectric plant itself there are no instruments, all being installed in the company's steam station, which is about 0.6 mile distant. The connections are such that, while the hydroelectric station is self-controlled and automatic, it is possible for the steam-plant operators to control the action of the water wheels and generators.

One of the most spectacular features is the speed with which the station goes into service. It requires just 37 sec. from the time the first switch operates until the first generator is under full load. The system of electric controls is a double one: namely, either by float switches and contact-making ammeters in the hydroelectric plant, or by remote-control switches on the benchboard at the steam power plant.

As regards the hydraulic equipment, it is stated that the normal head at the plant is 10 ft., but the head may vary from 8 to 11 ft.

The dam is composed of nine 60-ft. spillway sections, each of which automatically rises and falls with the flowage of the river, giving an automatic flashboard effect. Four motor-driven Tainter gates are installed at the intake to the flue. Wheel pits at the power house are independent of each other, and are equipped with 20-ft. Tainter gates on the upstream side and stop logs on the downstream side. The water wheels are of the Francis single-runner type, measuring 171 in. in diameter, and are rated at 540 b.hp., 60 r.p.m. and 84 per cent efficiency under a 10-ft. head.

Fig. 4 indicates the method of using the Tainter gate and the position of busses with respect to the control cabinets.

The original article describes in detail the electric controls. An interesting feature of these controls is the safety provisions, especially important because the station is left attendantless, except for one visit every eight hours by an employee from the steam plant, and therefore must take care of its own cases of trouble if any arise. To that end the machines are protected against hot bearings by thermostats of the spiral-spring type installed on each bearing. These thermostats are set to operate at 45 deg. cent. In common with all other

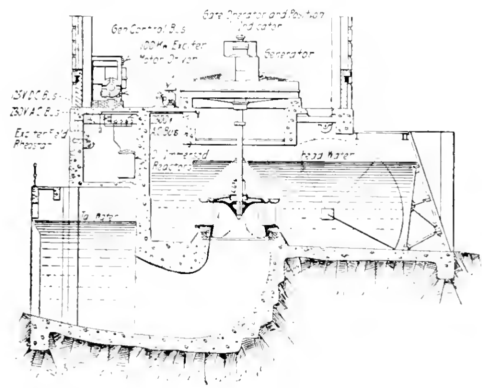

Fig. 4 Control Features of Cedar River Automatic Hydroelectric Plant

thermostatic control in the station, these bearing units operate to shut down the machine affected entirely, and keep it shut down until conditions again become normal, when the machine will start of its own accord. Thermostats are also used in connection with the control of the current-limiting reactors and the stator coils of the generators. (*Electrical World*, vol. 20, no. 22, December 1, 1917, pp. 1042 to 1045, 7 figs.; and *Power*, vol. 46, no. 24, December 11, 1917, pp. 790-793, 7 figs., *d*)

The Flow of Water in Siphons, Mark Halliday. Analysis of the flow of water in siphons. The writer considers two cases: first, that of a single siphon with one pump, and second, an amended arrangement.

In the case of the simple siphon shown diagrammatically in Fig. 5, he derives the following equation:

$$\frac{h_3}{l_2} = \frac{34 - h_1}{l}$$

where h_1 is as indicated in the diagram, l_2 is the length of the

pipe from A to C, h_2 H_2 H_1, as indicated in the diagram, and l is the length of the pipe in feet.

Unless this relationship holds, the siphon will not work continuously without a regulating valve. It will be noted that h_3 equally as much as h_2 governs the discharge. If h_2 is excessive, then v_3 tends to become larger than v_2, and cavitation in the pipes will result.

This explains the statement made so frequently that some siphons work better when the valve at the delivery end is partly closed. This must necessarily be the case, as the valve must be regulated until ($v_3 \times$ area at C) = ($v_2 \times$ area at B).

The same reasoning when applied to the Nicholson compound siphon results in the following deductions.

Fig. 6 shows the diagrammatic arrangement of the siphon; H_3, $\frac{P_3}{62.4}$, and v_3 are the static, pressure, and velocity energies per pound of water, respectively, at the air inlet N of the

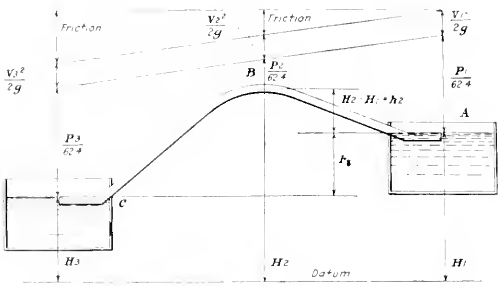

FIG. 5 SIMPLE SIPHON SHOWN DIAGRAMMATICALLY

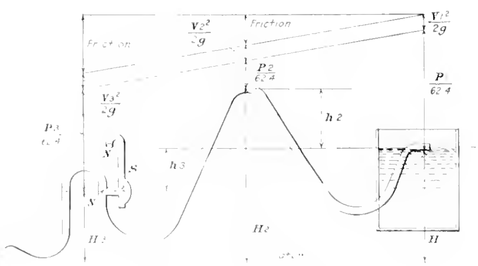

FIG. 6 AMENDED SIPHON

compound siphon. Then if the air inlet and trap N, S, N is fixed in a position according to the relationship in Equation [11], viz., such that $\frac{h}{l_2} = \frac{34 - h}{l_1}$, the compound siphon will discharge as much water as any simple siphon.

It has been assumed throughout that f, the coefficient of friction, is the same for the whole length of pipe considered; also, in order to simplify the argument, that $p_1 = 0$.

For a maximum discharge this would be so, but the analysis would hold equally well if p had a value of a few feet.

In that case the figure could be inserted to slightly modify the result in equation. (*Transactions of the Institution of Mining Engineers*, vol. 54, pt. 2, November 1917, pp. 107-112, 2 figs., *t*)

Internal-Combustion Engineering

LIGHT DIESEL ENGINE FOR MOTOR VEHICLES, Cole Newman. The writer claims that the modified-cycle Diesel engine with compound expansion would make this type applicable to motor vehicles, and further suggests the use of steam from jackets to modify cylinder pressures.

Germany is said to have just produced a Diesel aeroplane engine of the Junkers type weighing 3½ lb. per hp. It consists of double pistons in each cylinder working in opposite directions, giving a well-balanced engine practically free from vibration.

In this country it has been demonstrated that fuels heavier than kerosene cannot be successfully carburetted.

The problem is therefore how to handle the fuels. Automobile engineers hesitate to complicate the automobile engine with delicate injection apparatus, and, in fact, the amount that would be injected each time into the cylinder of an automobile engine of the Diesel type would be so small that it appears questionable whether it could be accomplished or not.

It would seem more practicable to atomize these heavy fuels and mix them with the ingoing air, after which they could be exploded by the heat of compression. An ordinary spark plug will not ignite such a mixture, or even if it were ignited a great deal of smoke and carbon deposit would result. But the compression of the charge to high pressure completely evaporates the finely atomized mist of fuel, and finally ignites it. Certain auxiliary features would be necessary for such an engine, viz., control of the point of ignition so as to prevent preignition, which might be accomplished either by varying the compression or by admitting variable amounts of water with the fuel.

The writer suggests the use of a compounded internal-combustion engine; for example, the following arrangement: a six-cylinder internal-combustion engine having four high-pressure cylinders of the four-stroke-cycle type and two low-pressure cylinders receiving exhaust from one or the other cylinder at every stroke. Assume that the four cylinders operate on the Diesel cycle by means of an atomized mixture of air with heavy fuel ignited by compression and controlled by water admission. Assume, in the first place, that the high-pressure cylinders only are water-cooled and the low-pressure cylinders properly lagged, as in the case of any steam engine. Assume that the heat of the water is utilized by permitting it to boil in the jackets. The steam from this water is admitted to the carburetor. Such as is not needed can be bypassed into the radiator. Therefore, the greater part of the heat lost to the jackets is restored to the cylinder at a lower temperature but greater heat mass. It enters the cylinder with the mixture of fuel and air, and controls the ignition point as desired. The mixture of the products of combustion with the greatly superheated steam after explosion passes through the exhaust valve to the low-pressure cylinder. The low-pressure cylinder, therefore, has not only that portion of the pressure derived from the high-pressure cylinder, but also the heat of the steam from the water jacket and of the exhaust, which is usually wasted, to turn into useful work. The cylinder also acts as a muffler, eliminating that apparatus entirely. Although a six-cylinder engine, it would give eight impulses per revolution of the crankshaft. (*Automotive Industries*, vol. 37, no. 26, December 27, 1917, pp. 1134-1135, *t*)

UNIFORMITY OF INTERNAL-COMBUSTION MOTORS WITH 6 AND 8 CYLINDERS, E. Pistolesi. (*Accad. Sci. Torino*, 52. 1, pp. 162-186, 1916-1917.) This question is of particular interest in connection with submarine motors where the use of a fly-

wheel is inconvenient. The author investigates the applicability of Wittenbauer's method to the case of multicylindered engines, and from the results obtained in specific cases he draws the following conclusions for engines of the same class as those investigated: (1) Four-stroke, six-cylinder motors with two compressors need a flywheel of moderate dimensions. The arrangement of the compressors has but small influence on the regulation. (2) Two-stroke, six-cylinder motors with their rods at an angle of 60 deg. need a small flywheel. The compressors have a preponderating influence on the regulation, and their position needs careful investigation. (3) Two-stroke, eight-cylinder motors with two compressors need no flywheel, provided all eight cylinders operate simultaneously. The compressors have a preponderating influence on the regulation, and with a suitable arrangement of these it is possible to attain a high degree of regularity. FIG. 7 ONE CYLINDER OF HOWARD CUFF-VALVE ENGINE

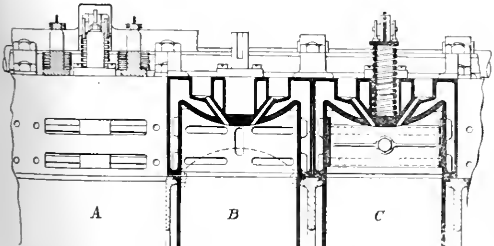

FIG. 8 THREE CYLINDERS OF HOWARD ENGINE

THE HOWARD CUFF-VALVE ENGINE. A type of engine combining to a certain extent the features of sleeve and poppet valves, which valve system is briefly described in the following paragraphs:

In a detachable cylinder head are arranged annular inlet and exhaust ports, both these rows of ports being covered and opened by the reciprocation of a broad but light ring somewhat resembling a wide piston ring. The ring is just wide enough to cover both sets of ports with sufficient overlap to prevent leakage. It is split and tongued at one point of its circumference, so as to make it elastic and to enable the compression and explosion pressures to press it tightly to the wall at the cylinder head. During these pressure periods of the cycle the valve is at rest and practically forms part of the cylinder-head wall, so that it can become only a few degrees hotter than the latter, which is water-cooled.

At the end of the explosion stroke the valve is moved downward, and immediately the exhaust port is uncovered the remaining explosion pressure is released. The valve then ceases to grip by reason of the internal pressure being released and can be moved merely to open and then to close the exhaust ports. When the valve has moved upward sufficiently to close the exhaust ports it continues this movement and immediately uncovers the inlet ports. At the correct moment it descends again and closes the inlets, remaining at rest in its mid-position during the next two strokes, held tightly to the cylinder-head wall over the ports by the internal pressures on the compression and explosion strokes.

The mechanism for operating the valve is shown in Figs. 7 and 9. The first shows the valve at the top and also the special cam and operating levers. Only one helical spring is shown, but in practice two concentric springs are used, wound in opposite directions to prevent periodicity.

In Fig. 8 is shown an outside elevation of one of the cylinders at *A*, indicating the height of the valve gear above the piston. *B* is a vertical axial section with the valve and its actuation removed to show the arrangement of the ports. The highest point reached by the piston is shown in broken lines, the top ring indicated being of the obturator type. *C* is a complete vertical section.

Fig. 9 shows the actuation of the cuff valve. This view

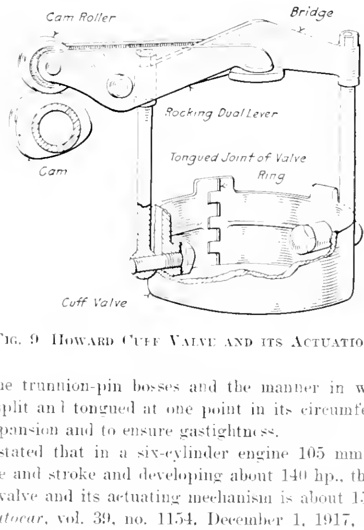

FIG. 9 HOWARD CUFF VALVE AND ITS ACTUATION

shows the trunnion-pin bosses and the manner in which the ring is split and tongued at one point in its circumference to allow expansion and to ensure gastightness.

It is stated that in a six-cylinder engine 105 mm. by 106 mm. bore and stroke and developing about 140 hp., the weight of each valve and its actuating mechanism is about 15 ounces. (*The Autocar*, vol. 39, no. 1154, December 1, 1917, pp. 540-543, 5 figs., *d*)

THE EFFICIENCY OF THE MOTOR, George Crouch. *Motor Boat*, vol. 14, no. 24, December 25, 1917, pp. 13-16. Brief consideration of the efficiency of the motor-boat engine, which the writer considers to be low in ordinary motor boats.

Lubrication

MICHELL'S AUTOMATIC LUBRICATING GEAR. Description of a new type of apparatus, the purpose of which is to lubricate bearings during starting and stopping by means of an automatic device which does not require the application of any auxiliary driving power. It was developed by Mr. Michell, the inventor of the Michell thrust and journal bearings. This

apparatus, which is really a specialized accumulator, requires no pumps for its operation, but is actuated entirely by the flow of oil which is maintained under pressure between the working surfaces of the bearing during running at normal speed.

As shown in Fig. 10, the top brass of the bearing is pivoted on a hollow stud making oil-tight contact with the brass through which a hole is drilled to its working surface at or near the point where the oil pressure is a maximum.

Assuming that the bearing is subject to a constant load of 500 lb. per sq. in. of the projected area of its brasses, oil is supplied during the normal running of the machine by the automatic action of the pivoted brass through the pipe and valves provided in the apparatus at a pressure of, say, 900 lb. per sq. in. The outer end of the hollow stud is connected by the pressure pipe to the accumulator cylinder constructed on the intensifier principle. As shown to the right in *B* and *C*,

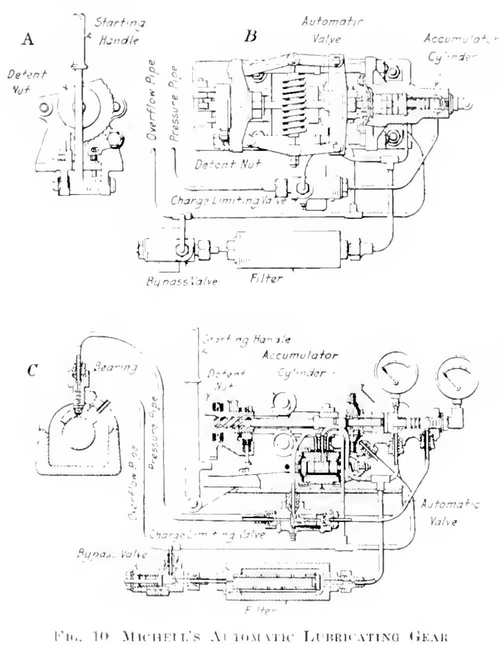

FIG. 10 MICHELL'S AUTOMATIC LUBRICATING GEAR

Fig. 10, it has a large and a small chamber in tandem, and is fitted with a stepped plunger turned to corresponding diameters. The pressure pipe delivers oil from the bearing into both chambers of the accumulator, forcing the plunger outwards and extending the loading springs, which are arranged to apply a practically constant load on the plunger of the accumulator by means of the toggle motion shown in *B*, Fig. 10.

When the outward motion of the plunger is completed it is held in that position by means of a detent nut and a pawl engaging with the nut, *A*, Fig. 10, whether the bearing continues to run or not, until the starting handle is shifted to the starting position. The accumulator is fully charged in a few minutes of normal running and the plunger remains at the outer end of its stroke during the remainder of the time that the motor is running and after it stops.

As the detent nut retains the plunger against the load imposed by the loading springs, *A*, Fig. 10, the latter imposes no pressure on the oil once the pawl is engaged, and little or no leakage takes place from the accumulator while the motor is stopped.

At starting the whole tension of the loading springs is applied to intensify the oil pressure in the small chamber of the accumulator up to, say, 2500 lb. per sq. in., oil at this pressure being discharged back through the pressure pipe to the bearing. By this means a film of oil is forced between the bearing surfaces lifting the rotor to the extent of, say, 1-1000 of an inch, and allowing it to start without solid friction on the bearing surfaces, with a comparatively very small starting current. Actual tests have shown that, whereas the coefficient of friction of the bearings on their brasses amounts to 0.18 under the usual conditions of starting, even if the starting is effected almost immediately after stopping so that the surfaces retain an appreciable amount of oil, the effective coefficient drops to less than 0.01 when the accumulator is used for starting.

In practice, one accumulator may supply all the bearings of the unit on which it is installed, and even can be made to serve several units. (*Engineering*, vol. 104, no. 2708, November 23, 1917, pp. 548-549, 7 figs., *d*)

CHARACTERISTICS OF SYSTEMS OF LUBRICATION FOR MOTORSHIPS, Thomas E. Coleman. *Motorship*, vol. 3, no. 1, January 1918, pp. 19-20, 2 figs., 2 charts. An abstract will be given in an early issue.

Machine Shop

HEAT TREATMENT AND TEMPERATURE MEASURING FOR SHELLS, J. R. VanWyck. Description of a method of heat treatment and temperature measuring that was used in the manufacture of two million 3-in. Russian shrapnel shells.

Lead-bath furnaces with room for eight shells and a preheater with room for 20 shells were used, all shells being heated and cooled in exactly the same manner. The shells in the preheater were heated from 700 to 900 deg. fahr. before being placed in the lead, pure lead being used for the bath and thermocouples being employed to take the temperature of the bath.

The article describes in detail the method of heating the bath, regulating the temperature of the lead and the signal system of colored lights employed for regulating the furnace. Base-metal thermocouples were used, these thermocouples being made right in the shop.

A very careful and systematic method of checking the working base thermocouples with the standard base-metal couples in the electric furnace was used once a week. The standard base-metal thermocouples were calibrated with the aluminum-rhodium thermocouples by removing the protecting tubes and tying together, but not touching, with asbestos tape. (*American Machinist*, vol. 47, no. 25, December 20, 1917, pp. 1087-1090, 10 figs., *d*)

MANUFACTURING OPERATIONS IN MAKING A GASOLINE MOTOR. *American Machinist*, vol. 48, no. 1, January 3, 1918, pp. 1-4, 15 figs. In this article are shown jigs and fixtures for machining the parts of a gasoline motor. The operations for machining the cylinder are taken in sequence and speeds, feeds and operating time are given. An interesting jig for drilling

the intake manifold, which is provided with a toggle equalizing mechanism for centering and holding the part, is worth noting.

Boring and Reaming Tools for 220- and 270-mm. French Shells, James Forrest. *American Machinist,* vol. 48, no. 2, January 10, 1918, pp. 70-72, 5 figs. The French type of shell is difficult to machine internally on account of its closed flat bottom and the overhang of the boring bar required. The contour of these shells is shown, and it will be seen that the inside surface is a combination of straight bore, taper bore, radius, and flat surface. How this surface is machined, with a description of the tools involved, is set forth in the article. As the operations and tools are the same for both shells, with allowances for different dimensions, the article treats of the 270-mm. shell but applies equally to both.

Use of Diamond Tools in the Shop, Frank A. Stanley. *American Machinist,* vol. 48, no. 2, January 10, 1918, pp. 49-51, 18 figs. A description of a variety of purposes to which diamonds may be put, such as turning, boring and reaming appliances for brass, iron and steel, hard rubber and compositions. Details of speeds, feeds and output are given.

Operating Characteristic of Motor-Driven Planers, C. E. Clewell. *Electrical World,* vol. 71, no. 2, January 12, 1918, pp. 87-90, 5 figs. Contains an analysis of the duty cycle of the planer and a discussion of the requirements of the driving equipment. The non-reversing motor is described and compared with the reversing equipment. Special emphasis is placed upon the method of control which is required. Incidental items, like the reduced flywheel effect due to the absence of pulleys with the reversing motor, the advantages of dynamic braking, remote control and the automatic action of the master switch in connection with the controller are also treated at some length. Economic advantages are set forth which may result directly from a careful study of cutting speeds of the return strokes, increasing the ratio of the latter to the former, eliminating the time losses from belt slip at the points of reversal, and the like.

Metal Frames and Fittings for Airplanes, Fred H. Colvin, Am.Soc.M.E. The writer describes the production of parts, which, in the earlier stages of aircraft engineering, used to be made of wood, but are now being made of metal. This applies in particular to tail-skid and rudder parts and details of control apparatus, especially the vertical stabilizer. The article is interesting, but not suitable for more detailed abstracting. (*American Machinist,* vol. 47, no. 25, December 20, 1917, pp. 1075-1077, 9 figs., *d*)

Spur Gearing Produced by the Rotary-Cutter Process, Henry E. Eberhardt. A historical article showing the development of this method of spur-gear manufacture and telling of the writer's connection with it.

The writer strongly defends the use of gears cut with disk cutters, but points out that other methods have also their legitimate field of application. (Paper read before the American Gear Manufacturers' Association at Chicago, September 1917, abstracted through *Machinery,* vol. 24, no. 5, January 1918, pp. 404-405, *h*)

Measuring Apparatus

Calibration of Anemometers, A. H. Anderson, Mem.Am. Soc.M.E. The writer claims that the method of calibrating anemometers by swinging in a short radius is quite erroneous, and describes another method believed to be more reliable.

Fig. 11 shows the anemometer mounted at the end of an arm 23½ ft. long. One end of the arm is centered on the post of a heavy iron tripod; the other end is supported by a rubber-tired wheel 10 in. in diameter. The trigger is operated by two cords, *A* and *B,* which are loosely supported by two rings near the center of rotation. The operator stands near the tripod, and by means of the cords the counting mechanism of the anemometer is engaged or disengaged while the arm is in rotation.

Such a test as this may be conducted in a large room with

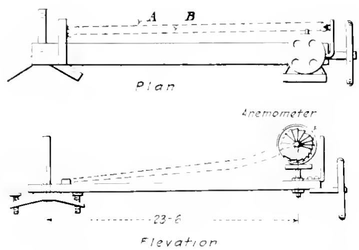

Fig. 11 Method of Calibrating Anemometers

a very smooth floor, and it is also necessary that the air in the room be undisturbed by drafts.

The arm may be rotated at practically any desired speed. At speeds greater than 1000 ft. per min., the rotation of the long arm becomes too rapid for convenient manipulation. The anemometer is then dismounted from the arm and the calibration continued by means of the pitot tube, a blast of air being provided from a centrifugal fan through a round pipe 24 in. in diameter.

This blast of air can be varied by changing the speed of the fan, and beginning with an air velocity of 1000 ft. per min. the reading of the anemometer is noted for the period of a minute and the indication of the differential gage is read. Similar runs are made at suitable intervals up to 4000 ft. per min.

In the original article the data obtained in the test are given in the form of tables; in addition two curves are given showing the relation betwen the true velocities and the velocities indicated by the anemometer. In Fig. 12 the points in the test made with the long arm are indicated by small circles, those obtained by pitot tubes by small triangles, and those obtained by the short arm by small squares. It appears that the short arm might give indications which are lower than with the long arm for equal peripheral velocities. Pin Measurement of Spur Gears, Reginald Trautschold. Pin measurement of spur gears has been developed for determining the pitch diameter of a gear. This system consists simply in measuring the distance between suitably proportioned pairs of pins that bear on the profile pitch lines of pairs of adjacent teeth. In gears with an even number of teeth the pins are inserted between pairs of diametrically opposite tooth spaces. In gears with an odd number of teeth, in which the tooth is diametrically opposite a tooth space, the second pin

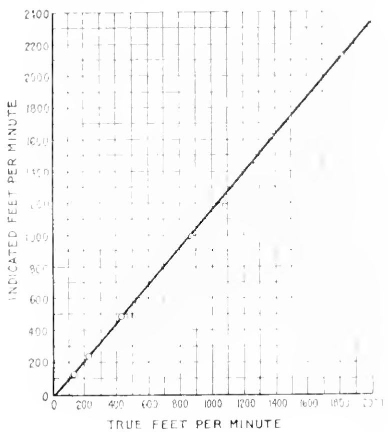

Fig. 12 True vs. Indicated Velocities by Anemometer

has to be placed in a tooth space most nearly opposite the first pin.

The writer describes the method of making pin measurements of gears with even and odd numbers of teeth, and also the method of finding the size of pin, and gives the following formulæ used in pin measurements:

$D = \frac{N}{P}$ .....[1] $R = \frac{D}{2}$ .....[2] $P_1 = \frac{3.1416}{P}$ ..[3]

$\beta = \frac{90}{N}$ ....[4] $\beta = \frac{45(P_1 + L)}{1.5708D}$ ....[5]

$Y = R \sin \beta$ ....[6] $Y_1 = R \sin \beta_1$ ....[7]

$B = R \cos \beta$ ....[8] $S = \sqrt{(0.25X^2 - Y^2)}$ ...[9]

$S_1 = \sqrt{(0.25X^2 - Y_1^2)}$.[10] $U = B + S$ ....[11]

$O = U \sin 2\beta$ ....[12] $H = O \cot 2\beta$ ....[13]

$W_1 = 2U$ for gears with even number of teeth...........[14]

$W = \sqrt{[O^2 + (H + U)^2]}$ for gears with odd number of teeth[15]

$W = W_1 + X$ ....[16] $X = 2R \sin \beta \sec a$ .....[17]

$X > 2Y$ but not $> 2Y \sec a$ ....[18]

Notation for Formulæ

Pitch diameter.. D
Pitch radius.. R
Number of teeth.. N
Diametral pitch.. P
Circular pitch.. P_1
Pressure angle.. a
Half angle subtended by tooth space.................... β
Half chordal width of tooth space..................... Y
Chordal ordinate.. B
Pin center amplitude.................................... S
Offset of pin center (for gears with an odd number of teeth) .... O
Pin center gear ordinate (for gears with an odd number of teeth).. H
Diameter of pin.. X
Pin center spacing.................................... W_1
Pin center radius.................................... U
Width over pins.. W
Backlash L
Half angle subtended by tooth space plus backlash....... β_1
Half chordal width of tooth space with backlash......... Y_1
Pin center amplitude with backlash..................... S_1

Strictly, a different size of pin ought to be used for measuring each gear that differs in the number of teeth or in pitch. It is obvious how inconvenient this would be. However, as the writer shows, the same size of pin may be employed for measuring a number of gears of the same pitch but differing considerably in the number of teeth. Within the range of the smallest and the largest gears of the same pitch cut in any particular shop, several diameters of pins may be required, but in all cases the diameter of the pin must fall within certain limits: namely, it must be greater than the standard diameter for the particular gear. Further, for any pin of suitable diameter the amplitude of the pin center, or the distance it lies above the chordal plane of the tooth space, is equal to the square root of the square of half the pin diameter minus the square of half the chordal width of the tooth space.

It is usually estimated that the widths of the teeth and the tooth spaces are equal, but in frequent cases a certain backlash is equivalent to increasing the arc of the pitch circle confined within the tooth space, which makes the pin sink farther down between the teeth. Nevertheless the contact points between the pin and the respective tooth profiles remain on the pitch circle, for the diameter of the pin must remain greater than the increased chordal width of the tooth space.

The original article contains a table giving the pin diameters of gears of 1 diametral pitch, having from 12 to 100 teeth with 14.5- and 20-deg. pressure angles, as well as the diameter of the gears when measured over the pins. (*Machinery*, vol. 24, no. 5, January 1918, pp. 406-409, 5 figs., *tp*)

Mechanics

Relation of Press Stroke to the Life of a Die, Wilhelm A. Schmidt, Mem.Am.Soc.M.E. In an article abstracted in The Journal for November 1917, E. F. Creager discussed the relation of the life of a punch and die with the increase in the length of stroke. The present article further discusses this subject and the writer offers an explanation of the cause of the increase in the life of a die when the press stroke is shortened.

The writer of the present article agrees with the statement of Mr. Creager, namely, that the stroke does not affect the life of the die if the presses are run at the same speed, but defines more fully what is meant by "speed" in this instance. If θ be the angle between the radius of the crank in a punch press and the line of motion of the arm, then the difference

in the cutting speeds between presses of $1\frac{1}{4}$-in. stroke and $\frac{5}{8}$-in. stroke will become less as this angle approaches zero. Consequently, in cutting very thin metals the velocity in either case will be nearly the same at the instant the metal is struck by the punch, but always slightly in favor of or less in the press having the shorter stroke, as velocities are absolutely equal only when angle $\theta = 0$ deg. or 180 deg., at which times the velocities are also zero. The writer believes that the difficulties in the velocities of stroke readily account for the increased life of the punch and die in the shorter-stroke press running at the same number of revolutions per minute of the crankshaft as that of a press with a longer stroke.

In a case wherein the press is constantly used for stamping metal 0.030 in. thick, is equipped with a roll feed and has a stroke of $1\frac{1}{4}$ in., the cutting velocity of the punch is 2.966 in. per sec. Assuming that this speed is such as will give a reasonable life to the punch and die, the same protection per life of the punch and die should be obtained in a shorter period of time by using a press with a $\frac{5}{8}$-in. stroke and increasing the revolutions per minute of the crankshaft until the cutting velocity of the punch is the same, namely, 2.966 in. per sec. The protection per press will naturally be greater, however, in the second case. (*American Machinist*, vol. 47, no. 26, December 27, 1917, pp. 1131-1132, 2 figs., *tp*)

TORSIONAL RESISTANCE OF ROLLED JOISTS, A. Föppl. (*Zeits. Vereines Deutsch. Ing.*, 61, pp. 694-695, Aug. 18, 1917.) A rod twisted by application of a couple M applied at its ends is deformed (withiu elastic limit) uniformly and in proportion to M. The twist δ in unit length $= M/JG$; where $G =$ modulus of shear $= 850{,}000$ kg.cm.^{2} for rolled iron, and J is a factor varying with the form of the section, and of the same dimensions (cm.^{4}) as the amount of inertia of the section. Both analytical and experimental methods are needed to solve the problem of determining the torsional resistance of sections used in practice. The author evolves a formula which he considers will be verified by experimental investigation. Almost all the formulæ hitherto available concerning the torsion of rods are based ultimately on St. Venant's researches. Some of St. Venant's formulæ are empirical formulæ intended to give at least approximate solutions for the torsional resistance of any section. These latter formulæ are less reliable. The older of St. Venant's approximate formulæ for rolled joists is $J = 4J_xJ_y/J_p$; where J_x and J_y are the moments of inertia referred to the two principal axes. This formula needs a correction factor which has only been worked out for the simplest cases. The later and more accurate formula is $J = F^4/40J_p$; where $F =$ sectional area. This formula is reasonably accurate for the old standard pattern of I-beam, but fails complete for modern broad-flanged I-beams.

The author's formula is derived from Bredt's (1896) and Prandtl's (1904) works. Most rolled joists may be considered as built up from narrow rectangles, with curves where one rectangle runs into another, these conditions being, however, of no importance as regards torsional resistance. Such sections approximate closely to the limiting case in which the narrow side of each rectangle is indefinitely small compared with the longer dimension, and in that case the torsional resistance of the whole section equals the sum of resistance of the individual rectangles. For a narrow rectangle, measuring l along its greater and d along its less dimension, $J = d^3l/3$. For a rolled joist section, built up from such rectangles, $J = \frac{1}{3}\Sigma d^3l$. This formula is not strictly true, because it is based on the unrealized assumption of infinitely thin rectangles. It is, however, a good approximation, capable of correction by factors determined by experiment. A simple formula for the maximum shear stress ($S_{\max.}$) set up in the section by the couple M, is $S_{\max.} = 3\,Md_{\max.}/d^3l$, where $d_{\max.}$ represents the smaller dimension of the thickest rectangle in the section. (*Science Abstracts*, Section A—Physics, vol. 20, pt. 11, no. 239, November 30, 1917, p. 507, *t*)

TYPE OF THREAD AS AFFECTING PIPE JOINTS. Data of experiments conducted by the research department of the National Tube Company. The purpose of this investigation was to develop a pipe joint having greater resistance to impact and vibration than the present joints. The investigation was chiefly conducted on 1-in. signal pipe, with some vibratory tests made on $1\frac{1}{4}$-in. extra heavy pipe and some internal-pressure tests on $2\frac{1}{2}$-in. steam pipe.

Table 1 gives a summary of the tensile-strength, drop and bending tests. Another table in the original article also gives data of vibratory tests. The different joints tested were: First, the regular Briggs thread on pipes and regular Briggs-thread steam coupling; second, round-bottom, sharp-top thread on pipe and regular Briggs-thread steam coupling; third, round-bottom, round-top 55-deg. thread on pipe and regular Briggs-thread coupling; and fourth, round-bottom, round-top 60-deg. thread on pipe and regular Briggs-thread coupling.

The air-pressure and water-pressure tests indicate that equally good joints can be made with mixed threads as with the Briggs thread alone, and, on the whole, the tests indicate that the different types of thread may be used together without any difficulty on the smaller-size pipe and with slight difficulty on the larger-size pipe. But when the thread galls there is some tendency to produce a leaky joint.

TABLE 1—TENSILE TESTS, DROP TEST AND BENDING TESTS ON THREADED PIPE

COMPARISONS OF UNANNEALED STEEL AND ANNEALED STEEL WITH ROUND AND SHARP THREADS AND WROUGHT IRON WITH SHARP THREADS. EACH SERIES OF STEEL PIPE TESTS WERE CUT FROM THE SAME 1-IN. STANDARD-WEIGHT PIPE

Series No.	Material	Kind of Thread	No. of Tests	Average tensile strength of joints, lb.	Drop test with 26-lb. weight Average number of blows at height of		Results: pieces broken in drop tests	Bending Tests	
					2 ft. 6 in.	4 ft.		Angle of bend, deg., average	Pieces broken
1	Black steel pipe as finished, with Briggs thread	Briggs	6	19,250	6.17	0.33	6	39 7	6
2	Black steel pipe annealed, with Briggs thread	Briggs	6	18,850	6.17	0.67	6	80 0	5
3	Black steel pipe as finished, with round thread	Round	6	21,325	7.5	6 7	1	103 5	0
4	Black steel pipe annealed, with round thread	Round	6	21,850	7.5	5	2	109 5	0
5	Black wrought iron as finished, with Briggs thread	Briggs	6	15,730	3 8	0	6	19 0	6

The following conclusions are drawn from the tests: (1) The round thread is superior to the Briggs thread in tensile strength of joint, in impact resistance, in the amount that threaded pipe may be bent, and in resistance of the joint to vibration. (2) Annealed joints are more resistant to shock, bending and vibration than the unannealed, and equally strong in tensile strength. (3) Steel joints are superior in every way to wrought-iron. Motor-Car Engineering

Steam Motorcycle. Description of a steam-driven motorcycle with a multitubular boiler. This boiler is 9 in. in diameter by 12 in. high, having 120 half-inch copper tubes and carrying a working pressure of 500 lb. A seamless steel tube is used for its construction and screwed-in ends electrically welded. The burner is simple type with pilot arranged for kerosene.

The engine is of the single-cylinder, double-acting type, 2-in. bore and $2\frac{1}{2}$-in. stroke, direct-coupled to the back tailshaft, having a reduction gear of 6.521. The horizontal tank, divided into two parts, contains fuel and water, the fuel being fed under pressure to the burner. The boiler feed is pumped through two water heaters: first through an exhaust-steam heater and then through a coil placed in the firebox. Superheated steam is used with the superheater again in the firebox. The exhaust is condensed as much as possible by a surface condenser, the hot water being returned to the boiler and the uncondensed steam escaping.

So far the machine has not proved satisfactory because of excessive weight, trouble in the burner in a high wind, small water-carrying capacity, and the wastefulness of the single-expansion engine working on steam at the above high pressure.

The writer adds that the rise in steam pressure and a sudden stop did not make one feel at all at ease in the saddle. (*The Motor Cycle*, abstracted through *The Autocar*, vol. 39, no. 1157, December 22, 1917, p. 629, 1 fig., *d*)

British Six-Ton Steam Truck. Description of a six-ton steam truck built by Atkinson & Co. of Preston, Lancashire, England, of interest especially because, while running on rubber tires, it uses coke as a fuel.

The steam generator is of the vertical water-tube type with tubes slightly inclined from the horizontal plane. The working pressure is 230 lb. per sq. in. In the combustion chamber is a double continuous coil of tubing forming a superheater through which the steam passes on its way to the engine. The generator is fired from the bottom by means of a chute. The driver merely removes the lid off the chute by his foot and allows a certain amount of coke to drop from the adjacent bunker into the firebox. It is claimed that with this arrangement the level of the fuel is within strict limits, leaving ample combustion space and giving a high thermal efficiency.

The special feature of the engine is the valves, shown in Fig. 13. These valves are large steel balls, of which there are four operated direct from camshafts by tappets. There are two camshafts; the steam inlets are placed above and the exhaust ports below. The exhaust camshaft is driven from the engine crankshaft by a shaft and beveled gearing, and from this through the beveled gearing and a vertical shaft the inlet

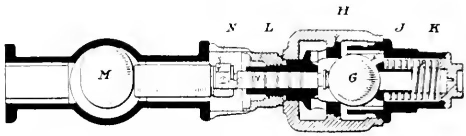

Fig. 13 Valve Mechanism of Atkinson Steam Truck Engine

camshaft is operated. All this mechanism is located in a casing and runs in oil, while a small oil pump on the exhaust-valve camshaft forces oil to all the cams through tubing.

The driving axle is of the solid type, one road wheel being rigidly mounted on the shaft and the other on a sleeve which surrounds the shaft and is carefully lubricated.

The vehicle is equipped with a steam brake which operates on a large drum bolted to the main driving sprocket on the rear axle. When steam is admitted to the rear end of the brake cylinder the piston and rod are forced inwards and the brake band is tightened round the drum by a lever. The brake is released by exhausting the steam from the cylinder. (*The Engineer*, vol. 124, no. 3232, December 7, 1917, pp. 494-496, 11 figs., *d*)

Heat Treatment and Temperature Measuring for Shells, J. R. VanWyck. See Section: Machine Shop.

The French 75-mm. Cannon. In the following list it is to be noted that entries marked * refer to publications which are not in the Library of the Engineering Societies and have not been examined.

1898.—New Field Artillery, 1898. (*Jour. U. S. Artillery*, v. 10, p. 267, et seq.) Based on an article in *Revue de Cavalerie*. Gives reasons leading to the adoption of the 75-mm. cannon, together with some data on dimensions, projectile, etc.

1898.—75-Mm. Rapid Fire Field Material, 1898. (*Revue Militaire Suisse* for Feb.)*

1900.—Modern Field Artillery, The Schneider-Canet Systems, 1900. (*Engineering*, vol. 69.) I, pp. 540-542; description of the 75-mm. gun, illustrations, diagrams. II, pp. 573-577; continues description, etc., of 75-mm. gun, giving data on eight different types, 16 figs. III, pp. 609-611, and IV, pp. 643,646; further descriptions of 75-mm. gun types and illustrations of carriages, limber, brakes, etc. V, pp. 671-672; further description of 75-mm. gun types and illustrations.

1900.—New French Field Gun, 1900. (*Artilleri-Tidsskrift*, Jan. and Feb.)*

1900.—Schneider-Canet Quick-Firing Guns and Howitzers for Field Service, 1901. (*Engineering*, vol. 72. I, pp. 72-75; II, pp. 107-110; III, pp. 210-211; IV, pp. 246-249.) Description of the 75-mm. and other guns, together with tests carried out by Schneider & Cie. at the Harfleur long-range proving ground.

1901.—Schneider-Canet Rapid Fire Field Material, 1901. (*Revue Militaire Suisse* for May.)*

1902.—Field and Position Artillery Material from Schneider & Cie., and Experimental Firing with Same at Harfleur, March, 1901, 1902. (*Artilleri-Tidsskrift*, May, June, Sept., Oct.)*

1902.—Curey and Pesseaud, Capts., Artillerie à l'Exposition Universelle de 1900. Paris, 1902-7, 335 pp., 183 figs., 22 plates. Frs. 6.50.*

1902.—Notes on Rapid-Fire Field Artillery, 1902. (*Jour. U. S. Artillery*, vol. 17, pp. 23 et seq.; translated from the French.) Pp. 38-41 give general information on the 75-mm. gun, as far as published.

1902.—Junken, Chas. A., French Field Artillery, 1902. (*Jour. U. S. Artillery*, vol. 18, pp. 21-32; transl. from *Militär Wochenblatt*, Jan. 1 and 8, 1902.) Description of the 75-mm. gun substituting the 90-mm. gun, including general type and construction as far as known, limber, service, battery, methods of fire.

1902.—French 75-Mm. Gun, Illustrated, 1902. (*Revue Militaire Suisse* for Jan.)*

1902.—Mitteilungen über Gegenst. d. Art & Gen.-Wesens, March, 1902.*

1903.—Hero, Capt. A., Jr., French Rapid-Fire Field Artillery, 1903. (*Jour. U. S. Artillery*, vol. 19.) I, pp. 35 et seq.: diagrams and description of the 75-mm. gun (pp. 37-46), including breech mechanism, carriage, recoil brake, tire brake, shields. II, pp. 164-185; description and diagrams of "laying apparatus and instruments used in preparation for and execution of fire," including collimator, level, graduated plates, methods of pointing, preparation for fire, formation of batteries, etc. III, pp. 47-60; methods of firing, execution of fire, rules for firing, battery organization, etc.

1903.—French Field Artillery Material—75-Mm, 1903. (*Revue d'Artillerie* for October.)*

1905.—Adoption of the 75-Mm. R. F. Gun for Horse Batteries, France, 1905. (*Belgique Militaire* for Dec. 24.)*

1906.—Notes on the 75-Mm. Gun and Regulations Therefor, 1906. (*Revue de Cavalerie* for Aug. and Sept.)*

1907.—Modern French Field Guns, 1907. (*Engineering*, vol. 84, pp. 775-778.) Detailed description and diagrams of the Schneider-Canet 75-mm. field guns, pattern "P D," including dimensions, weights, pressures.

1907.—Olivier, Lieut. L., Material de Montagne Demontable de 75 a Tir Rapids, Systeme Schneider-Danglis. (1907-1912), 40 pp., 15 figs., Frs. 1.25.*

1907.—Range Table of French 75-Mm. Gun, 1907. (*Artilleristische Monatschrift* for Sept.)*

1907.—Brems- und Vorholvorrichtung des 75-Mm. Feldgeschützes M. 97, 1907. (*Mitteilungen über Gegenstände des Art & Gen.-Wesens*, vol. 38, p. 1046.) A description of the brake, etc., of the 75-mm. gun, based on an article in the *Deutsches Offizierblatt*, etc.

1908.—Wirkung der Sehrapnells der 75-Mm. Kanone M 97, 1908. (*Mitteilungen über Gegenst. des Art & Gen.-Wesens*, vol. 39, pp. 168-169.) A quotation from Aubrat's Exercises de Service en Campagne, giving results of trials of the 75-mm. shrapnel for comparative effect.

1911.—Ordnance, 1911. (Article in Encyc Brit., 11th ed., vol. 20, pp. 189-235.) Table 9, p. 211, and Table 21, p. 214, give data on 75-mm. guns (France); see also ill. plate 3 and descriptive notes on p. 221.

1911.—75-Mm. Halbautomatische Kanonen in Mittelpivotlafette der firma Schneider & Cie., 1911. (*Mitteilungen über Gegen. des Art & Gen.-Wesens*, vol. 42, pp. 764-768, with plates and figs.) Detailed description and diagrams, characteristics, dimensions, breech, limber, munition, etc.; also addition of shield, p. 340.

1913.—*Revue d'Artillerie*, December 1913.

1913.—Moliere, Capt. H., Notes sur le Canon de 75 et Son Règlement, à l'Usage des Officiers de Toutes Armes. 4th ed., paper, Paris, 1913, Berger-Levrault, 136 pp., 65 illustrations, Frs. 2.*

1914.—Artilleries de Campagne Française et Allemande, Le Canon Français de le Canon Allemand de 77, 1914. (*Génie Civil*, vol. 65, pp. 385-394.) Description, illustration and comparison of the two guns, the French 75 especially complete, and partly based on Commandant Buat's l'Artillerie de Campagne, Son Histoire, Son État Actuel. (Abstract in *Jour. Franklin Inst.*, 1917, vol. 183, pp. 374-375.)

1914.—*Revue d'Artillerie*, July 25, 1914.*

1914.—Règles à Observer pour le Tir du Canon de 75 par-dessus les Troupes Amies, 1914. (*Génie Civil*, vol. 65, pp. 334.) From an article by Com. A. P. Jamet in *Revue d'Artillerie*, July 25.

1915.—Dalman, Antonio Ferrer, El Cañon Krupp y el Schneider de 75-mm., 1915. Barcelona, Feliu y Susanna, 39 pp. Pp. 29-35 describe the French 75-mm., 11 figs.; a chapter on the construction of guns is included on pp. 37-39.

1915.—"Soixante Quinze," 1915. (*The Engineer*, vol. 119, pp. 77-78.) Based on an article in Génie Civil, giving descriptions of breech, block, recoil cylinder (as far as published), wheel brake, elevating gear, ammunition wagon, fuse setter, time and percussion fuse, ballistic data, etc.

1915.—75-Mm. Automobile Battery in France, 1915. (*Kriegstechnische Zeitschrift* for May-June.)*

1915.—Range Table of the French 75-Mm. Gun, 1915. (*Artilleristische Monatsehrift* for Oct. 14.)*

1915.—Specifications for High Explosive Shells, 1915. N. Y. Industrial Press, 44 pp., chap. 5, pp. 38-44, gives specifications for the French 75-mm. high-explosive shell.

1915.—French 75-Mm. and 105 Mm. Field Guns, 1915. (*Engineering*, vol. 100, p. 535, and pp. 559-561.) Gives dimensions, ballistic data, and a general description of these two sizes of guns.

THE INSPECTION OF SCREW GAGES FOR MUNITIONS OF WAR, J. H. Bingham Powell. *American Machinist*, vol. 47, no. 25,

December 20, 1917, pp. 1065-1073, 5 figs. See abstract in The Journal for January 1918, pp. 108-109.

Les Modèles Actualles de Torpilles Automobiles. *Le Génie Civil,* tome 71, no. 1843, December 8, 1918, pp. 365-371, 21 figs. Description of modern types of automatic torpedoes.

Power Plants

Methods of Drying Out Flooded Power Plant Equipment, Norman L. Rea. *Power,* vol. 47, no. 2, January 8, 1918, pp. 46-48, 4 figs. Discusses various schemes that may be employed for drying out electrical equipment after a power plant has been flooded, and points out the advantages and disadvantages of the various methods.

Presses

Electric Baling Presses. *Engineering,* vol. 104, no. 2710, December 7, 1917, pp. 600-602, 9 figs.

Hydraulic Forging Presses. *The Iron Age,* vol. 100, no. 25, December 20, 1917, pp. 1480, 1522-1524.

Pumps

Duty Trials on Two 24-Million Gallon Pumping Units. *Power House,* vol. 10, no. 11, November 1917, pp. 313-316, 3 figs.

Air Pumps and Condensers. *Engineering,* vol. 104, no. 2712, December 21, 1917, pp. 664-665, 1 fig.

Some Notes on Air-Lift Pumping, A. W. Purchas. *The Journal of the Institution of Mechanical Engineers,* no. 8, December 1917, pp. 613-650, 11 figs., 4 tables. An extensive discussion of air-lift-pump design and operation. An abstract will be given in an early issue of The Journal.

Railroad Engineering

The Tank Car, E. S. Way. *Railway Review,* vol. 61, no. 26, December 29, 1917, pp. 801-803.

Mechanical Problems in the Design of Electric Locomotives, W. K. McAfee. *The Electric Journal,* vol. 15, no. 1, January 1918, pp. 16-19, 8 figs.

The Transportation of Perishable Commodities, Dr. M. E. Pennington. *Railway Age,* vol. 64, no. 2, January 11, 1918, pp. 119-124, 10 charts.

New Four-Cylinder Express Locomotive. *The Railway Gazette,* vol. 27, no. 25, December 21, 1917, pp. 681-683, 4 figs. Description of a new 4-6-0 express locomotive recently completed at the works of the Great Central Railway, England. The cylinders use highly superheated steam on the single-expansion principle. The number of superheater elements has been increased from the usual 24 units to 28 units. The addition of another row of superheater units makes a considerable difference in the maintenance of steam temperature in long boilers, especially when the engine is working under high-duty conditions.

The "Ruston" Oil Locomotive. *Engineering,* vol. 104, no. 2709, November 30, 1917, pp. 569-571, 7 figs.

New York Central 4-8-2 Type Locomotives. *Railway Age Gazette,* vol. 63, no. 26, December 28, 1917, pp. 1167-1170, 4 figs., 1 chart, 1 table.

Screw-Spike and Tie-Plate Test, W. C. Cushing. *Bulletin of the American Railway Engineering Association,* vol. 19, no. 200, October 1917, pp. 3-255, illustrations and charts.

Refrigeration

Multi-Stage Compression Plant of Central Cold Storage Co. *Power,* vol. 47, no. 3, January 15, 1918, pp. 74-78, 6 figs. This modern two-unit ammonia plant of 500 tons refrigerating capacity employs the new D. I. Davis system of multi-stage compression with cooling of vapor between stages. It is expected to save in power 25 per cent over the standard simple compressor and to develop one ton of refrigeration on less than 25 lb. of steam per hour.

Steam Engineering

The Divergence of Steam Nozzles, Gerald Stoney. As in most of the textbooks on steam turbines the theory of the divergence of steam nozzles is not fully given, the following method of calculation may be of interest.

In textbooks on steam turbines it is shown that in expanding adiabatically from a pressure p_1 to a pressure p_0 the velocity of the steam is

$$C_0^2 = 2gH_1 \frac{\gamma}{\gamma - 1}\left(1 - z^{\frac{\gamma-1}{\gamma}}\right)$$

where

$$z = \frac{p_0}{p_1} \text{ and } H_1 = 144\, p_1 V_1$$

At the throat

$$z_t = \left(\frac{2}{\gamma+1}\right)^{\frac{\gamma}{\gamma-1}}, \text{ where } z_t = \frac{p_t}{p_1}.$$

so that at the throat

$$C_t^2 = 2gH_1 \frac{\gamma}{\gamma+1} \ldots\ldots\ldots\ldots\ldots\ldots [1]$$

If A_t is the area of the nozzle at the throat, and A_0 that of the exit, the equation for continuity gives

$$\frac{A_0}{A_t} = \frac{C_t\ V_0}{C_0\ V_t} \ldots\ldots\ldots\ldots\ldots\ldots [2]$$

where V_t and V_0 are the volumes of the steam at the throat and exit of the nozzle, respectively.

As

$$p_0 V_0^{\gamma} = p_t V_t^{\gamma}$$

and as

$$p_t = p_1 z_t = p_1 \left(\frac{2}{\gamma+1}\right)^{\frac{\gamma}{\gamma-1}} \ldots\ldots\ldots\ldots [3]$$

we have

$$\frac{V_0}{V_t} = \left(\frac{p_t}{p_0}\right)^{\frac{1}{\gamma}} = \left(\frac{2}{\gamma+1}\right)^{\frac{1}{\gamma-1}} z^{-\frac{1}{\gamma}} \ldots\ldots\ldots [4]$$

Putting Equations [1], [2] and [4] into [5],

$$\frac{A_0^2}{A_t^2} = \frac{\gamma-1}{\gamma+1}\left(\frac{2}{\gamma+1}\right)^{\frac{2}{\gamma-1}} \frac{1}{z^{\frac{2}{\gamma}}\left(1 - z^{\frac{\gamma+1}{\gamma}}\right)}$$

$$= \frac{\gamma-1}{2}\left(\frac{2}{\gamma+1}\right)^{\frac{\gamma+1}{\gamma-1}} \frac{1}{z^{\frac{2}{\gamma}} - z^{\frac{\gamma+1}{\gamma}}} \ldots\ldots\ldots [5]$$

an equation for the flare of the nozzle.

As z is fractional, a more convenient form for calculation is obtained by writing $X = \frac{1}{z} = \frac{p_1}{p_0}$, X being the expansion by pressure; and then [5] becomes:

$$\frac{A_0^2}{A_t^2} = \frac{\gamma-1}{2}\left(\frac{2}{\gamma+1}\right)^{\frac{\gamma+1}{\gamma-1}} \frac{X^{\frac{\gamma+1}{\gamma}}}{X^{\frac{\gamma-1}{\gamma}}-1}$$

As the ratio of the specific heats, or γ, may be considered as practically constant in these equations for the adiabatic expansion of steam, it will be seen that the flare depends only upon the amount of expansion by pressure in the nozzle; that is, that it is the same for a nozzle expanding from 200 lb. per sq. in. to 20 lb. as from 10 lb. to 1 lb. Since, however, the value of γ for saturated steam is less than for superheated steam, the flare is slightly less in the latter case.

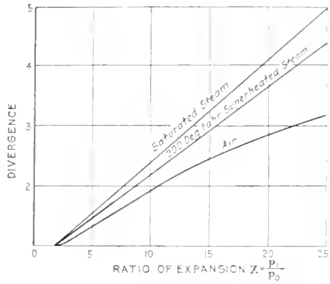

Fig. 14 Theoretical Divergence of Steam Nozzles

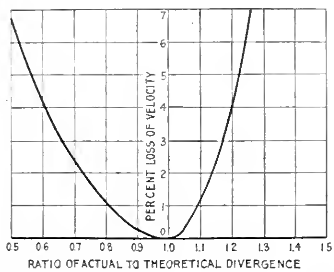

Fig. 15 Ratio of Actual to Theoretical Divergence

For the critical expansion $z = \left(\frac{2}{\gamma+1}\right)^{\frac{\gamma}{\gamma-1}}$, the value of A_0/A_t is unity; and for the ordinary values of γ, which are from 1.135 for saturated steam to 1.3 for superheated steam, the relation between the flare and the ratio of expansion in the nozzle is approximately a straight line, except for large degrees of expansion.

It may be mentioned that in the common case, where the steam is at first superheated and then becomes wet as it expands, the average value of γ is between the value for superheated steam, namely, 1.3, and that for saturated steam, 1.135.

Fig. 14 shows the relation between the flare and the amount of expansion for saturated and superheated steam, and also for air. In this diagram "divergence" is to be understood as the ratio of area at any section of the nozzle to the throat area. In practice nozzles are generally given rather less flare, since it is much more important to have too little flare than too much flare.

That this is so is well shown by the curves given by Mr. W. J. Goudie from an analysis of data published by Dr. Steinmetz. A combination of these curves is given in Fig. 15. Generally friction in a nozzle slightly increases the flare, but in practice that is negligible. Mr. H. M. Martin has pointed out to the author that

$$\frac{\lambda}{\lambda-1} = \frac{1}{\eta_1}\,\frac{\gamma}{\gamma-1}$$

where λ is, for frictional flow, the apparent value of the index in pV^{λ} = constant, and η_1 is the efficiency. For many purposes this formula is more conveniently written as

$$1-\frac{1}{\lambda} = \eta_1\left(1-\frac{1}{\gamma}\right)$$

As in practice, the efficiency is always above 90 per cent, it is easily seen that the losses in the nozzle have little effect on the flare. (*Engineering*, vol. 104, no. 2710, December 7, 1917, p. 597, *t*)

New Method of Increasing the Evaporation in Boilers, Carl Hering. Data of tests on the boiling of water made mainly in open metal cups over a gas flame.

The writer claims to have discovered a new thermal principle in the boiling of water.

He states that when a flame impinges upon the outside surface of any water-boiling vessel which is constantly maintained at a far lower temperature than the flame by the water on the other side of the metal wall, a thin film of gas forms on the flame side of the surface and offers an enormously high resistance to the passage of heat through it. If the temperature of the flame is taken at about 1300 deg. cent. and that of the water is about 100 deg. cent., there is a fall of temperature of about 1200 deg. cent. (2160 deg. fahr.) through this film, which appears to be only about 0.005 in. thick. This means an extremely high thermal resistance.

Present researches indicate that first there is a point at which it is no longer of advantage to further increase this artificial resistance, and next that this point seems to be reached when the temperature of the surface is about midway between that of the flame and that of the water; hence, for water boiling this would be about 725 deg. cent., which means a dull-red heat.

A practical way to introduce this artificial resistance is by means of lugs on the flame side of the surface, which have such a length and diameter that the heat flow through them will maintain their hot ends at about a dull-red heat.

The same thermal resistance may be produced by a long, thick lug or by a shorter but thinner one, provided the ratio of the length to the cross-section is the same, but the quantity of heat flowing through each lug will, of course, diminish with its cross-section.

Several factors are also involved in the determination of the best spacing of the lugs. Theoretically, the best condition would appear to be a very thick bottom, or very thick-walled boiler tubes, that is, one lug of the diameter of the bottom surface of the vessel; but it will be found that this thickness would have to be several feet, making this form of resistance entirely impracticable. The other extreme would be to have innumerable very thin, short lugs close together, which is also impracticable for obvious reasons.

Coming down to practical constructions, it was found that by spacing the same-sized lugs further apart, the greater freedom of the circulation of the hot gases between them increased the flow of heat through each lug, but as there were then fewer lugs per square inch of surface, the total heat flow into the vessel, as a whole, was reduced.

It was further found that the lateral surfaces of the lugs are of particular importance. The lugs may be made slightly conical, so that their bases cover practically the whole surface, while the thinner ends are more apart, to permit the further circulation of the hot gases.

Two interesting series of tests were made with lugs of various dimensions. The data of the tests are shown in Fig. 16. The results of the first series of tests are shown in *A*. In this series the lugs were of the same diameter but of different lengths, the relative flow of heat through a lug being approximately indicated by the heavy vertical lines above them. It is significant that the flow of heat through lug 3 was greater than through lug 4, although 4 is very much longer than 3.

The next series of tests with lugs of the same length but of different diameters is diagrammatically represented in the same manner in *B*. There again we see that there are certain ranges of dimensions of lug diameter which give the best results. Thus, 5 and 6 have approximately the same rate of flow, but the rates of flow between 4 and 5 are obviously different.

In the cup without lugs the heat flow corresponded to the evaporation of about 17 lb. per sq. ft. per hour. But the rate of flow through the lugs themselves was found to be as high

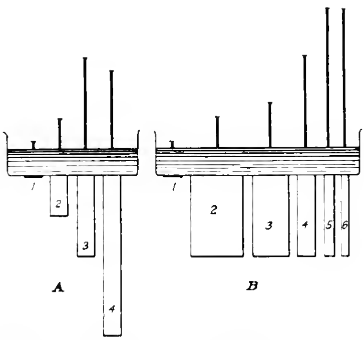

Fig. 16 Comparison of Heat Transmission Through Plates with and without Lugs

as 467 lb. per sq. ft. per hour, or about 27 times as high as in the cup without lugs. The spheroidal state which limits this rate was not yet reached.

The present investigation opens up important possibilities, but, as the writer states, requires further research for the determination of various factors which affect the efficiency of the lugs. (*Power*, vol. 47, no. 1, January 1, 1918, pp. 10-13, 3 figs., *eA*)

Determining Boiler Efficiency by CO_2 Analyses and Flue Temperatures, Haylett O'Neill. *Power*, vol. 47, no. 2, January 8, 1918, pp. 52-55, 12 figs., 2 tables. Gives several charts with the aid of which the boiler efficiency may be closely approximated when the CO_2 and flue temperatures are known. The purpose of the article is to enable the engineer to obtain valuable operating data for practical use by means of simple and cheap instruments.

The Logan, West Virginia, Power Plant. *Power*, vol. 46, no. 25, December 18, 1917, pp. 818-822, 8 figs. This power station, with a capacity of 2000 boiler hp., has with an addition of boiler equipment supplanted 14,000 boiler hp. at surrounding coal mines. A total load of 21,000 kw-hr. was carried shortly after the starting up of the plant by one 500-hp. boiler for 24 hours, the day load averaging 1500 kw-hr. This one 500-hp. boiler did the work of 4100 hp. of isolated mine boilers as formerly operated.

Standard Propelling Engines for British Standard Ships. *Engineering*, vol. 104, no. 2709, November 30, 1917, p. 569.

Thermodynamics

Heat Transfer in Tubes, W. Nusselt. (*Zeits. Vereines Deutsch. Ing.*, 61, pp. 685-689, Aug. 18, 1917.) The author gives the following formula for the mean coefficient of heat transference a_m in a tube of length L:

$$(a_m d/\lambda_m) = 0.03622 (d/L)^{0.054} (dw\gamma_m c_{pm}/\lambda_m)^{0.786} \ldots\ldots\ldots [1]$$

Here d = tube diameter, λ = thermal conductivity of the gas or superheated steam, w = velocity of flow, γ = weight of unit volume of gas, c_{pm} = true specific heat of the gas at constant pressure. If T_w and T_o are the absolute temperatures of the tube wall and gas respectively, $\lambda_m = [1/(T_w - T_o)] \int_{T_o}^{T_w} \lambda dT$, $c_{pm} = [1/(T_w - T_o)] \int_{T_o}^{T_w} c_p dT$, and $\gamma_m = [\gamma_o T_o/(T_w - T_o)] \log_e(T_w/T_o)$. In these formulae, γ_o = weight of unit volume of gas at T_o. If T_w and T_o be nearly the same, λ_m, c_{pm}, and γ_m can then be taken to be the values of λ, c_p and γ at $\frac{1}{2}(T_w + T_o)$. Equation [1] is true only for velocities of flow exceeding Reynolds's critical velocity. Denoting $(dw_m c_{pm}/\lambda_m)$ by A, Equation [1] is true for $A > 1000$ if $p = 1$ atmos., and for $A > 7000$ if $p = 16$ atmos. The formula applies to other sections of flow as well as to plain tubes. If F = cross-sectional area of an annular passage and S that part of the circumference through which heat enters or escapes, the value of d to be used in Equation [1] is $4F/S$. If heat flows through the whole of the outer circumference while the inner tube serves merely as a throttle, $d = (d_1^2 - d_2^2)/d_1$. Equation [1] is applicable either to the heating or the cooling of a gas; the heat-transfer coefficient remains the same if the gas and tube temperatures be interchanged. The three fractions composing Equation [1] are dimensionless, i.e., the constants of the formula are the same whatever the system of units employed; only one system must be used in each fraction, but it need not be the same in all three fractions. The formula applies accurately only when the temperature of gas changes little along the tube; variation in a along the tube may then be calculated easily. In the first half of the tube a is about 8.6 per cent greater than in the second half. The temperature of gas at the end of the tube is $T_2 = T_w + (T_1 - T_w)e - d_m F/W$; but if $(T_1 - T)$ be considerable, as in boiler tubes, the only way at present is to consider such short sections that the temperature fall in each case is small.

To eliminate the tedium of evaluating Equation [1] for individual cases, the author gives tables and charts which also show how a varies with the factors on which it is dependent. The data and curves presented relate to air and steam, these being the gases of greatest technical importance. The formulæ, tables, and curves are for: (1) Thermal conductivity as a function of temperature. (2) Heat-transfer coefficients for various

tubes and gas temperatures. The coefficient decreases at constant tube temperature with increasing air temperature; also, with increasing tube temperature, at constant air temperature. (3) Influence of air velocity and pressure, tube diameter and length. Finally there is a chart for the graphical determination of a for air in any case within wide limits. Experience shows that a for boiler-flue gases or the exhaust from combustion engines differs only 1 or 2 per cent from the values for air at equal pressure.

The velocity of gas flowing through a tube with which it exchanges heat varies along the tube inversely with the absolute temperature of the gas. The product $w\gamma$ is independent of tube length. A fundamental distinction is that whereas a decreases with rising air temperature when the air velocity and tube temperature are constant, a increases with temperature when the mass of air passing a given section in unit time is constant. Due to two conflicting factors, the heat-transfer coefficient for air which is warmed as it flows through a tube passes through a minimum value. (*Science Abstracts*, Section B—Electrical Engineering, vol. 20, part 11, no. 239, November 30, 1917, pp. 402-403, *t*)

Specific Heat of Water, W. R. Bousfield. The writer, in a paper before the Royal Society in 1911, gave figures for specific heats of water at temperatures from 0 to 80 deg. cent. Since then, other investigators, in particular Callendar, by using other methods, have secured data somewhat different from those obtained by the writer, who accepts the superior accuracy of the results of Callendar's new method in the range above 55 deg. cent.

In the range from 0 to 55 deg. the new method has not been applied and the difficulties which it was specially designed to meet at higher temperatures hardly exist in the lower range; since in that range the vapor pressure of water is so small that an accurate correction for evaporation may be easily made.

The corrected figures obtained by the writer were found to be closely in line with those of other observers and indicate that the mean specific heat from 13 deg. to 26 deg. is almost exactly equal to that from 26 to 39 deg., which gives the minimum value in the neighborhood of 25 deg.

The writer points out and discusses the salient differences in this lower range of temperature between his investigations and those of Callendar, but he points out that the course of his curve from 0 to 40 deg., with its minimum at about 25 deg. is in general agreement with the curves of Luedin, Rowland, and Bartoli and Stracciati, while the course of the Callendar and Barnes curve, with its minimum at about 38 deg., differs from all.

The results of a paper which will appear in the *Philosophical Transactions* dealing with the specific heat of certain solutions confirm the writer's position of the minimum very substantially. This paper deals with the determination of the mean capacity of a Dewar vessel in which a novel method of regulating the electric current was adopted. There the position of the minimum was such as to confirm the view of the author, a further confirmation of the same having resulted by a consideration of the actual values of the specific heats of potassium-chloride and sodium-chloride solutions. In this last instance it was found that the temperature-specific-heat curves for saturated solutions indicate a nearly straight-line law from 0 to 39 deg. between specific heat and temperature, a fact which can hardly be a mere coincidence.

The writer points out that until the course of the specific-heat curve from zero to 40 deg. can be considered as definitely settled, there must remain a doubt as to the value of the 20-deg. calorie, amounting to one part per thousand. The reasons for adopting as the standard calorie the mean specific heat over the interval which, undoubtedly, included the minimum point and which is easily reproducible, were stated in a former communication by the writer. The interval from 13 deg. to 55 deg. satisfies all the particular conditions and there remains the difference of over 1/10 of one per cent between the writer's value for the interval and that which results from Callendar's latest figures. (*Proceedings of the Royal Society*, Series A, vol. 93, no. A 655, October 9, 1917, pp. 587-591, *et*)

Varia

On the Solutions of Partial Differential Equations of First Order at the Singular Points, Toshizo Matsumoto. *Memoirs of the College of Science, Kyoto Imperial University*, vol. 2, no. 5, August 1917, pp. 255-292.

Physics of the Air, W. J. Humphreys. *Journal of The Franklin Institute*, vol. 185, no. 1, January 1918, pp. 83-117, fig. 47, 6 charts. Serial article (chap. 10).

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

LIBRARY NOTES AND BOOK REVIEWS

ARTICLES of interest from the Library of the four Founder Societies, selected list of accessions during the month, and reviews of books of special importance prepared by members of the A.S.M.E. and others particularly qualified.

Annual Report of Library Board

THE Library Board administering the Libraries of the American Society of Civil Engineers, The American Society of Mechanical Engineers, the American Institute of Electrical Engineers and the American Institute of Mining Engineers, maintained as the Joint Library of the United Engineering Society, has just issued its annual report for 1917.

The Board for 1917 consisted of:

Edward D. Adams	John W. Lieb
Harrison W. Craver	W. M. McFarland
J. V. Davis	Harold Pender
Alfred D. Flinn	Calvin W. Rice
George A. Harwood	Lewis D. Rights
Alex. C. Humphreys	Samuel Sheldon
A. M. Hunt	W. I. Slichter
Charles Warren Hunt	Jesse M. Smith
F. L. Hutchinson	E. Gybbon Spilsbury
J. H. Janeway	George C. Stone
Bradley Stoughton	

Mr. George C. Stone was added to the Board on November 23, 1917, as representative of the American Institute of Mining Engineers, to take the place of Mr. E. F. Roeber, whose death occurred on October 17, 1917.

The number of visitors to the Library for the year was 11,371, an average of 40 daily. The service given to both visitors and non-visitors was in the form of 551 searches and 59 translations. The photostat installed in 1916 has proved its value unequivocally; the number of orders was 791, calling for 7853 prints.

Accessions to the Library during the year amounted to 2337 pieces, and the collection totaled, on December 31, 1917, 132,778 volumes and pamphlets.

Arrangements were made during the year for the publication of brief descriptive reviews of new books in the publications of the Founder Societies. The leading publishers of technical books in America have furnished review copies for this purpose, thus enabling the Library to present to both engineers and manufacturers a timely and comprehensive list of nearly all important technical books.

The Library has been the recipient of some very valuable gifts, chief among them being the presentation by the American Society of Civil Engineers of the book stacks used in their building. These have been removed to the Engineering Society Building and have been erected on the fourteenth floor, where they provide the additional room which is so badly needed at the present time. Another valuable gift consisted of 505 volumes relating to electricity, presented to the American Institute of Electrical Engineers by Theodore N. Vail.

Cataloguing has progressed along two lines: one dealing with new accessions, the other with material already in the catalogue. As stated in the 1916 report, the catalogue lacks consistency and needs fundamental and thoroughgoing revision. With a view to this, possible methods of revision have been studied carefully and the process to be followed during the coming year has been selected, so that the work can be begun as soon as the stack room is completed.

There have been some changes in the Library Staff, chief among them being the resignation of Mr. William P. Cutter as Librarian. Mr. Cutter rendered faithful, skilled service during a period of six years, during which the Library has increased in size and usefulness and has acquired a leading position among libraries of engineering. As his successor, the United Engineering Society engaged, in accordance with the recommendation of the Board, Harrison W. Craver, Librarian of the Carnegie Library of Pittsburgh.

The components of a good library are an adequate collection of books and periodicals, a good system of cataloguing, convenient and rapid means of bringing books to readers and an efficient, willing staff.

Considering the Library of the United Engineering Society in these respects, it can first be said that the book collection is, within its limits, probably the best in this country, if not in the world. Widening the scope of the Library by including more adequately some branches of engineering, such as chemical engineering, should be considered.

The present catalogue needs reconstruction, as has already been indicated. This will receive the first attention during 1918 and every activity not immediately essential will be subordinated to it, with the hope that substantial progress can be made.

Certain rearrangements of the reading-room furniture are desirable. The staff is satisfactory and is sufficiently large for the present normal work of the Library.

HARRISON W. CRAVER.

BOOK NOTES

Everyman's Chemistry. The Chemist's Point of View and His Recent Work Told for the Layman. By Ellwood Hendrick. Harper & Bros., New York, 1917. Cloth, 5x8 in., 374 pp. $2.

An extremely readable account of recent progress in the science underlying the dye, the high explosive, potash, nitrogen—written for the purpose of enabling the general reader to obtain something like an adequate conception of the principles of its organic and inorganic branches, and of the important relations they bear to modern life and industry and war.

The Essentials of Descriptive Geometry. By F. G. Higbee, M. E., Professor and Head of Department of Descriptive Geometry and Drawing, The State University of Iowa. John Wiley & Sons, Inc., New York, 1917. Second Edition. Cloth, 6x9 in., 218 pp., 170 illustrations. $1.80.

In preparing his text the author has aimed to include only those portions of descriptive geometry which possess industrial utility. The subject is discussed from the point of view of the draftsman, and of the three hundred odd problems given a large proportion are of an eminently practical nature. In the present edition a chapter on tangent planes and lines has been added.

Principles of Natural Philosophy. By F. J. B. Cordeiro. Spon & Chamberlain, New York, 1917. Cloth, 5¼x8 in., 113 pp., 24 figs. $2.50 net.

A compact, closely reasoned study of force, energy and motion, so interwoven, however, with the frequent speculations of the author that he has selected the Newtonian title used as being more appropriate than mechanics, dynamics or physics. The methods of the calculus are used throughout.

Library Accessions

American Concrete Institute. Proceedings 13th annual convention. Vol. XIII. Purchase.

Analysis of British Wartime Reports on Hours of Work as Related to Output and Fatigue. No. 2, Nov. 1917. National Industrial Conference Board. *Boston, 1917.* Gift of National Industrial Conference Board.

Appropriation Acts of Pennsylvania, 1917. *Harrisburg, 1917.* Purchase.

Apuntes sobre las mejoras materiales aplicables a la America Latina. By L. R. Pezuela. *Lima, 1869.* Purchase.

Ascertainment of Machinery Values and Losses. By John Hankin. Read before the Insurance Society of New York. *New York, 1916.* Gift of Insurance Society of New York.

Le Béton Armé a la Portée de Tous. By Léopold Malphettes. *Paris, 1917.* Purchase.

Birds of the Anamha Islands. (U. S. National Museum, Bull. 98.) *Washington, 1917.* Purchase.

Board of Civil Engineers. Proceedings and Report, to consider the subject of the construction of a rail and highway bridge across the Missouri River at St. Louis. *St. Louis, 1867.* Purchase.

Chemistry of Colloids, The. Part 1, Kolloidchemie by Richard Zsigmondy. Trans. by Ellwood B. Spear. Part II, Industrial Colloidal Chemistry by Ellwood B. Spear. A chapter on Colloidal Chemistry and Sanitation by John Foote Norton. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 9 x 6 in., 288 pp., 38 illus., $3. Gift of the publisher.

Chemistry of Dyestuffs. By M. Fort and L. L. Lloyd. *Cambridge, 1917.* Purchase.

Chicago, Ill., Public Efficiency Bureau. The City Manager Plan for Chicago. *Chicago, 1917.* Gift of Public Efficiency Bureau.

Cretaceous Theropodous Dinosaur Gorgosaurus. (Canada. Dept. of Mines. Memoir 100). *Ottawa, 1917.* Purchase.

Description of the Recently Discovered Petroleum Region in California, with a Report on the Same. By Professor Silliman. *New York, 1864.* Purchase.

Digest of the Game, Fish and Forestry Laws of Pennsylvania, 1917. *Harrisburg, 1917.* Purchase.

Dimensions and Weights of Gun Implements. *Washington, 1874.* Purchase.

Discourse of the Romane Foot, and Denarius; from Whence, as from Two Principles, the Measures and Weights, Used by the Ancients. By John Greaves. *London, 1647.* Purchase.

Distribution of Bird Life in Colombia; a Contribution to a Biological Survey of South America. (American Museum of Natural History, Bull. vol. 36, 1917). *New York, 1917.* Purchase.

Electrical New York as Seen by Vernon Howe Bailey. *New York, 1916.* Gift of New York Edison Co.

Electric Vehicle Hand-Book, The. By H. C. Cushing, Jr., and Frank W. Smith. 5th ed. H. C. Cushing, Jr., *New York,* (copyright *1917*). Flexible cloth, 7 x 4 in., 388 pp., 172 illus., $2. Gift of the authors.

Exporters' Directory of Japan, The. Imperial Commercial Museum of the Department of State for Agriculture and Commerce. *Tokyo, 1917.* Flexible cloth, 9 x 6 in., 26 pp. $2.50.

Ferro-Carril Central Trasandino. Informe del Ingeniero en Jefe. D. Ernesto Malinowski. Seccion del Callao y Lima a la Oroya y Presupuesto de la Obra. *Lima, 1869.* Purchase.

Ferro-Carril de Arequipa. Documentos relativos a esta empresa. *Lima, 1869.* Purchase.

Flotation. By T. A. Rickard and O. C. Ralston. Mining & Scientific Press. *San Francisco, 1917.* Cloth, 9 x 6 in., 416 pp., 131 illus., $3. Gift of the publisher.

Galvanic Batteries and Electrical Machines, as used in torpedo operations. Parts I and III. By J. P. Merrell. *Newport, R. I., 1874, 1875.* Purchase.

General Electric Company's Medical Service and Hospital. *Schenectady, n. d.* Gift of C. M. Ripley.

Geology of Massachusetts and Rhode Island. (U. S. Geological Survey. Bulletin 597). *Washington, 1917.* Purchase.

Graphics. By H. W. Spangler. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 9 x 6 in., 95 pp., 88 illus., $1.25. Gift of the publisher.

Greenhouses. By W. J. Wright. Their Construction and Equipment. Orange Judd Company, *New York, 1917.* Kegan Paul, Trench, Trübner & Co., Ltd., *London, 1917.* Cloth, 8 x 5 in., 269 pp., 131 illus., $1.60. Gift of the publisher.

Gunnery Notes. *U. S. Navy, 1871.* Purchase.

Gunpowder as an Element in the Problem of Modern Ordnance. (Naval Ordnance Paper, No. 1). *Washington.* Purchase.

Handbook for Cane-Sugar Manufacturers and Their Chemists, A. By Guilford L. Spencer. 6th ed., enl. John Wiley & Sons, Inc., *New York, 1917.* Leather, 7 x 4 in., 561 pp., 97 illus., $3.50. Gift of the publisher.

Hand-Made Paper and Its Water Marks: a bibliography. By Dard Hunter. Marlborough-on-Hudson. *New York, 1916.* Gift of Technical Association of the Pulp and Paper Industry.

Harbor and Port Terminal Facilities and Works. By H. McL. Harding. *Washington, 1917.* Gift of author.

Health of the Worker. Dangers to health in the factory and shop and how to avoid them. By C. E. A. Winslow. Metropolitan Insurance Company. *New York, 1918.* Gift of Metropolitan Insurance Company.

Hydraulic Mining Débris in the Sierra Nevada. (U. S. Geological Survey. Professional paper 105). *Washington, 1917.* Purchase.

An Introduction to Theoretical and Applied Colloid Chemistry. By Dr. Wolfgang Ostwald. The World of Neglected Dimensions. Authorized translation from the German by Dr. Martin H. Fischer. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 9 x 6 in., 232 pp., 45 illus., 1 port., $2.50. Gift of the publisher.

Iron Ore Occurrences in Canada. Vol. I, with maps. (Canada, Department of Mines, no. 217.) *Ottawa, 1917.* Purchase.

Laws of Pennsylvania, 1917. *Harrisburg, 1917.* Purchase.

Lecture on the Late Improvements in Steam Navigation and the Arts of Naval Warfare, with a Brief Notice of Ericsson's Caloric Engine. By J. O. Sargent. *New York, 1844.* Purchase.

Magnalite Piston Design. Ed. 2. By Jos. Leopold. *New York, 1917.* Gift of Walker M. Levett Co.

Mineral Industries of the United States. Coal products: an object lesson in resource administration. (U. S. National Museum. Bull. 102, pt. 1). *Washington, 1917.* Purchase.

Mineral Industries of the United States. Sulphur—An example of industrial independence. (U. S. National Museum, Bull. 102, pt. 3). *Washington, 1917.* Purchase.

Modern Gasworks Practice. By Alwyne Meade. D. Van Nostrand Co., *New York, 1916.* Purchase.

Modern Seamanship. Ed. 7. By Austin M. Knight. *New York, 1917. Purchase.*

Movable Torpedoes, Submarine Guns and Rockets, Lecture on Drifting and Automatic. By F. M. Barber. *Newport, R. I., 1874.* Purchase.

Nature of Solution. By Harry C. Jones. D. Van Nostrand Co., *New York, 1917.* Purchase.

New Dictionary of the French and English Languages. By E. C. Clifton and A. Grimaux. 2 vols. *Paris, n. d.* Purchase.

New York City. Building Code as amended to July 17, 1917, with laws and regulations governing building construction. *New York, 1917.* Purchase.

Non-Technical Chats on Iron and Steel. By LaVerne W. Spring. Their Application to Modern Industry. Frederick A. Stokes Company, *New York* (copyright *1917*). Cloth, 8 x 6 in., 358 pp., 294 illus., $2.50. Gift of the publisher.

L'organizzazione industriale secondo il Taylor. Estratto dalla Rivista di artiglieria e genio, vol. III, 1917. *Roma, 1917.*

Panama Canal. Annual Report of the Governor. 1917. *Washington, 1917.* Purchase.

Pennsylvania Railroad Company. Instructions governing the use of explosives. *Philadelphia, 1913.* Gift of Company.

PETROLEO CRUDO COMO COMBUSTIBLE. By Eduardo M. Wilson. *n. p. n. d.* Gift of author.

PRACTICAL PYROMETRY. By Ervin S. Ferry, Glenn A. Shook, Jacob R. Collins. The Theory, Calibration and Use of Instruments for the Measurement of High Temperatures. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 8 x 6 in., 147 pp., 73 illus., $1.50. Gift of the publisher.

A PRACTICE BOOK IN ELEMENTARY METALLURGY. By Ernest Edgar Thum. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 9 x 6 in., 315 pp., 59 illus., $2.75. Gift of the publisher.

PRODUCTION OF COAL AND COKE IN CANADA, 1916. *Ottawa, 1917.* Purchase.

PROPERTIES OF STEAM AND AMMONIA. By G. A. Goodenough. 2d ed. John Wiley & Sons, Inc., *New York, 1917.* Cloth, 10 x 7 in., 126 pp., 7 illus., 3 pl., $1.25. Gift of the publisher.

PULPWOOD CONSUMPTION AND WOOD-PULP PRODUCTION, 1916. (U. S. Dept. of Agriculture). Purchase.

PUTNAM'S CORRESPONDENCE HANDBOOK. A work of reference designed to promote efficiency in business correspondence. By Eleanora Banks. *New York, 1914.* Purchase.

RADIO COMMUNICATION. By John Mills. Theory and Methods with an Appendix on Transmission Over Wires. McGraw-Hill Book Co., Inc., *New York, 1917.* Leather, 7 x 5 in., 205 pp., 126 illus. Gift of the publisher.

RANGE OF ELECTRIC SEARCHLIGHT PROJECTORS. By Jean Rey, translated by J. H. Johnson. Van Nostrand, *New York, 1917.* Purchase.

RECLAIMING THE ARID WEST. By George Wharton James. The Story of the United States Reclamation Service. Dodd, Mead and Company, *New York, 1917.* Cloth, 9 x 6 in., 411 pp., 67 illus., $3.50. Gift of the publisher.

THE REFFYE GUN. Ordnance Notes. *1873.* Purchase.

RELATION OF PURE SCIENCE TO INDUSTRIAL RESEARCH. By J. J. Carty. (From Smithsonian Report for 1916 p. 523-31). *Washington, 1917.* Purchase.

SHORTER CONTRIBUTIONS TO GENERAL GEOLOGY, 1916. (U. S. Geological Survey Professional paper 98). *Washington, 1917.* Purchase.

SOUTH AMERICAN OPINIONS ON THE WAR, translated from the Spanish by P. H. Goldsmith. *Washington, 1917.* Gift of Carnegie Endowment for International Peace.

STANDARD WIRING FOR ELECTRIC LIGHT AND POWER. By H. C. Cushing, Jr. 23d ed. As Adopted by the Fire Underwriters of the United States. In Accordance with the National Electrical Code, with Explanations, Illustrations and Tables Necessary for Outside and Inside Wiring and Construction for All Systems. Together with a Section on House Wiring. H. C. Cushing, Jr., *New York, 1917.* Leather, 7 x 4 in., 360 pp., 47 illus. Gift of the author.

SUBMARINE BOATS AND THEIR APPLICATION TO TORPEDO OPERATIONS, lecture on, by F. M. Barber. *Newport, R. I., 1875.* Purchase.

SURFACE WATER SUPPLY OF THE UNITED STATES, 1914. Pt. IX—Colorado River Basin (U. S. Water Supply Paper 389); Pt. X—The Great Basin. (U. S. Water Supply Paper 390). *Washington, 1917.*

—— 1915. Pt. VIII-Western Gulf of Mexico Basins. (U. S. Water Supply Paper 408). *Washington, 1917;* Pt. III—Ohio River Basin (U. S. Water Supply Paper 403). *Washington, 1917.*

—— 1916. Pt. VIII—Western Gulf of Mexico Basins (U. S. Water Supply Paper 438). *Washington, 1917.* Purchase.

SYSTEM OF GEOMETRY AND TRIGONOMETRY; TOGETHER WITH A TREATISE ON SURVEYING. 4th ed. By Abel Flint. *Hartford, 1812.* Gift of C. T. Church.

TABLES OF CUBIC CONTENTS OF LEVEE EMBANKMENTS. Designed by Arthur Alvord Stiles. Bulletin No. 5 of the State Reclamation Department of Texas, June, 1917. State Reclamation Department. *Austin, 1917.* Leather, 9 x 6 in., 212 pp., 1 pl.

TABLES OF VELOCITY OF WATER IN OPEN CHANNELS DERIVED FROM KUTTER'S FORMULA. By Arthur Alvord Stiles. Bulletin No. 6 of the State Reclamation Department of Texas, August, 1917. State Reclamation Department, *Austin, 1917.* Leather, 9 x 6 in., 130 pp.

TALKING GLOVES FOR THE DEAF AND BLIND: THEIR VALUE TO MEN INJURED IN THE PRESENT WAR. *Cleveland, 1917.* Gift of Harold T. Clark.

TEACHING PHYSICS TO STUDENTS OF ENGINEERING, report of the Committee. By Dayton C. Miller. (Reprinted from the Proc. of the Soc. for the Promotion of Engineering Education, v. 24, 1916). Gift of D. C. Miller.

TESTS OF OXYACETYLENE WELDED JOINTS IN STEEL PLATES. (Illinois Univ. Bulletin no. 98, Engineering Experiment Station) *Urbana, 1917.* Purchase.

THEORETICAL RESEARCHES ON THE EFFECTS OF GUNPOWDER AND OTHER EXPLOSIVES. By M. E. Sarrau, translated by Lieut. Meigs. Part 1. *Washington, 1883.* Purchase.

THOMAS' REGISTER OF AMERICAN MANUFACTURERS, 1917. 9th ed. Thomas Publishing Company, *New York, 1917.* Cloth, 12 x 10 in., 3900 pp., $15. Gift of the publisher.

TRATTATO DI CHIMICA ANALITICA APPLICATA. Vol. II. By Vittorio Villavecchia. *Milano, 1917.* Purchase.

UNION OF SOUTH AFRICA. Department of Mines and Industries. Annual Report of the Government Mining Engineer. 1916. *Pretoria, 1917.* Purchase.

UNITED STATES RIFLES AND MACHINE GUNS. By Fred H. Colvin and Ethan Viall. A Detailed Account of the Methods Used in Manufacturing the Springfield. 1903 Model Service Rifle; also Descriptions of the Modified Enfield Rifle and Three Types of Machine Guns. McGraw-Hill Book Company, Inc., Hill Publishing Co., Ltd., *New York, London, 1917.* Cloth, 12 x 9 in., 332 pp., 2347 illus., $3. Gift of the publisher.

WHITEHEAD TORPEDO, lecture on. By F. M. Barber. *Newport, R.I., 1875.* Purchase.

ZAPATA CHRONOGRAPH. By J. D. Marvin. Translated from the Madrid Edition. *Annapolis, 1875.* Purchase.

GIFT OF THE SOCIETY FOR ELECTRICAL DEVELOPMENT.

AIMS AND ACHIEVEMENTS. A brief summary of what the Society is accomplishing for its members and for the entire electrical industry.

HOW TO MAKE YOUR SHOW WINDOW PAY YOUR RENT. A "how to" booklet with a series of suggestions covering the fundamentals of selling through window displays.

INDUSTRIAL HEATING AS A CENTRAL STATION LOAD. Part 2—The utilization of the heat of electric energy.

MORE THAN 3000 USES FOR ELECTRICITY (revised edition).

A $3,000,000,000 INDUSTRY PULLS TOGETHER, being an official record of America's electrical week. Dec. 2-9, 1916.

GIFT OF ALFRED D. FLINN.

The Library has received a complete file of the contracts and drawings issued by the Board of Water Supply of the City of New York, in which the canvasses of bids have been inserted, adding greatly to the reference value of the set. The gift was obtained through the kindness of Mr. Alfred D. Flinn, Deputy Chief Engineer of the Board of Water Supply.

GIFT OF ILLUMINATING ENGINEERING SOCIETY.

The Illuminating Engineering Society has presented to the Library some eighty volumes relating to the gas industry, among which are many of decided interest. These had been presented to them by Dr. William Paul Gerhard, but the Society, believing that the convenience of all would be best served by collecting all engineering material together, has secured Dr. Gerhard's consent to this disposition of his gift.

GIFT OF NATIONAL LIME MANUFACTURERS' ASSOCIATION—HYDRATED LIME BUREAU.

BULLETIN A-5. Modern Methods in Concrete Construction.

—— A-6. Promoting the flow of concrete in pipes and forms.

—— F-3. Watertight concrete.

—— J. Ideal mortar for brick masonry. Mortar no. 5.

PAMPHLET E. Standard specifications for hydrated lime plastering.

—— K. Improving concrete roads—the effect of hydrated lime.

TREATISE ON INTERIOR PLASTERING FOR THE USE OF ARCHITECTS, OWNERS, CONTRACTORS. *1915.* By Lawrence Hitchcock.

TESTS AND USES OF HYDRATED LIME. By R. C. Haff.

GIFT OF EDWARD WEGMANN.

Mr. Edward Wegmann has presented to the Library a bound set of the contract specifications issued by the Aqueduct Commissioners of New York City from 1885-1901, covering the contracts in connection with the Croton Aqueduct. The estimates and bids for the construction of the various parts of the work have been inserted in this set, adding much to its value for reference.

THE NEW BY-LAWS GOVERNING SECTIONS OF THE A.S.M.E.: WHAT THEY PERMIT AND ENCOURAGE

By LOUIS C. MARBURG, NEW YORK, N. Y.

Member, Committee on Local Sections

THE task has been assigned to me to speak on the new Local Sections By-Laws[1] of The American Society of Mechanical Engineers. I will say something regarding their history and will try to point out a few paragraphs that appear of interest in connection with the routine operation of the Local Sections. I will consider mainly, however, those characteristics of the new by-laws which seem to show a new spirit and which recognize modern tendencies in the engineering profession and elsewhere; and will also devote some consideration to these tendencies themselves and to the activities they suggest.

In the Technical Section of this issue of The Journal appear the first papers before the Local Sections of the Society this season.

The Sections papers will be continued in the April and May issues, and then again in the issues following the Spring Meeting. Several good papers are on hand.

In connection with these Sections papers it is of interest to note that the Local Sections, acting on the suggestion of the Committee on Local Sections, are now appointing papers and research sub-committees to develop the relations between the Sections and the Meetings and Publication Committees of the Society.

This is a significant move—it means that the way is being paved for the complete nationalization of the proceedings of the Society, so that these proceedings will truly constitute a record of mechanical engineering progress in America.

Previous to the acceptance of these new by-laws, the Constitution, By-Laws and Rules of the Society contained but scant reference to any Local Section activity. There was a paragraph in the Constitution permitting the formation of professional sections and geographical groups, and there were rules regulating both in a rather indefinite way, and taking little account of the great difference between them. The Local Sections movement increased rather independently of these rules; and it might seem that more elaborate by-laws were quite unnecessary. The Committee on Local Sections felt, however, that a certain amount of uniformity in matters of routine was advisable and that, furthermore, the experience of older and successful Sections might be made available, in the form of by-laws, to new Sections. Therefore it appointed some time last year a sub-committee consisting of Prof. Walter Rautenstrauch and myself to prepare a draft for new by-laws. This draft was submitted to the Local Sections delegates a year ago for criticism and suggestions; it was modified in accordance with some of the ideas expressed at that time and submitted to the Council. After being referred to the Committee on Constitution and By-Laws for proper codification and comment, and after some joint work between this Committee and your committee, these by-laws finally emerged and were passed by the Council at its October 1917 meeting. If any details do not meet with the Sections' approval, it should be remembered that all laws are compromises, except those made by an autocrat, which generally please but one person—the autocrat himself.

The New By-Laws and Their Interpretation

The by-laws naturally contain several paragraphs pertaining to matters of routine, such as the procedure in forming a new Section, the definition of territory and membership, the personnel and duties of the local committees, the method and time of election, contributions on the part of the parent Society and the use of such contributions, the use of uniform stationery, etc., all of which aim at unifying Sections procedure, to the strength of the organization.

More interesting than these is the paragraph on "Local Section members," granting to each Section the right to include a new class of membership, if it so desires—local members of the Section who are not members of the parent Society. Any dues collected from such local members belong to the Section, and the parent Society has no control over their disbursement. Opinions will vary as to the advisability of permitting this class of local membership,—they will vary mainly on account of the difference in problems that Sections have to meet and owing to the difference in local conditions. Some Sections have such members, others may find it useful to have them, others may not. The decision rests with the Sections themselves.

Useful Activities of the Sections

On Section activities the new by-laws contain a number of paragraphs. Here, of course, there is a great deal to say, for the activity of the Sections is necessarily the activity of the Society. Papers shall be read, that is a matter of course. It has always been the main function of our Society and there is no new suggestion in this. Attention, however, should be called to the paragraph suggesting that such papers, after being read before the Sections, be submitted to the Committee on Meetings and to the Publication Committee for possible further use. It is urged that this practice be generally adopted. It will furnish to The Journal much valuable material. It will also tend to improve the quality of papers read before Sections, because the author of a well-prepared address will be assured of a larger audience, particularly if his paper is accepted for a general meeting of the Society and published in the Transactions.

Another recognized activity consists in social functions and the fostering of acquaintanceship among engineers, an important and a very useful part of the Sections work.

The Keynote of All Sections Work—Coöperation

Foremost, however, of all the activities mentioned in the by-laws appears to be coöperation. Coöperation with other

[1] Address delivered before the Conference of Local Sections Delegates of the Society at the Annual Meeting of The American Society of Mechanical Engineers, New York, December 1917.

engineering organizations, be they local engineering societies or sections of other national societies, and coöperation with other organizations of whatever kind, in any enterprise having the approval of the Section. We cannot too earnestly recommend the cooperation with other local sections and the affiliation with local engineering societies or clubs. The experience in St. Louis, Philadelphia, Milwaukee and other cities has been so extremely satisfactory that it should encourage similar combinations in other localities. The recognition of coöperation in other than strictly professional work, which is accorded in the paragraphs referred to, is a radical innovation in the policy of our Society, but more will be said on this particular point.

By-Laws Constructive, Not Obstructive

Perhaps after my introductory remarks about a new spirit expressed in our By-Laws, this short résumé has proven disappointing. Perhaps a casual glance over these by-laws does not show anything so strikingly novel. Perhaps also, and probably, some real or contemplated activity in some of the Sections has already been along the lines suggested in all the paragraphs on Sections activity. Let me express right here and most emphatically, that these by-laws are not believed to point the way to something never thought of before, they do not contain a single new and brilliant thought; but they do, it is believed, take proper cognizance of changing ideas and of newer tendencies. They do not stand in the way of certain aims which should be encouraged and which are welcomed by the engineer of vision and by the firm believer that the engineering profession has higher ideas than perfection in the calculation of stresses and the design of machinery and structures.

By-Laws Recognize Modern Tendencies

In discussing more fully the spirit of the new by-laws and the degree to which they show recognition of modern tendencies, we must take these tendencies themselves into consideration.

First, these by-laws seem to express a spirit, not only of democracy, but of a particular kind of democracy. Democracy, which in its political sense means majority rule, we have of course always had in our Society whenever the members were sufficiently interested to use their power. But even if members everywhere could be induced to take an equal amount of interest in the affairs of our Society, majority rule alone would not yet be satisfactory. Majority rule of a certain kind is unendurable and more tyrannical than the rule of many an autocrat. If vital questions affecting a small community are decided by the majority of fifteen or twenty million voters in a huge country, it is small consolation for this community to know that a decision against its wishes and its vital interests has been reached by the rules of democracy. Not only may injustice result from having a government so far removed from those it governs, but there may arise a feeling of helplessness and a lack of interest. Bertrand Russell says in one of his books: "The modern great state is harmful from its vastness and the resulting sense of individual helplessness. Even in a democracy, all questions except a very few are decided by a small number of officials and eminent men; and even the few questions which are left to the popular vote are decided by a diffused mass-psychology, not by individual initiative."

Sections Require, and Retain, Self-Determination

It is this feeling of helplessness, this suppression of the individual initiative, which we must guard against even in an organization having only 9000 voters instead of fifteen or twenty or thirty millions. Engineers in districts remote from New York require an organization nearer to themselves than the national society, nearer not only in distance but in interest. It is to this need that the whole Sections movement owes its existence, and it is self-evident that, in order to do their best, such local organizations require the greatest degree of self-determination and the greatest freedom from outside interference consistent with harmonious coöperation with the parent Society. Sections must manage their own affairs: they will know their local needs and conditions, and as long as they do not commit the national society by any of their actions, little control from headquarters will be needed; and, no doubt, affairs will be handled properly and to the best interests of the Sections themselves.

Let nobody fear that the position of the parent society will be impaired by this policy. Let nobody fear sectarianism. The danger of our present world organization lies not in too little centralization of power but in the excess of such centralized power. Government too far removed from the individual voter is offensive, in fact, it is dangerous. Let us realize this, let us have strong sections taking interest in local affairs. Home rule, which to so great an extent has been responsible for the success of our national government, must be the order of the day in the world that is to come. Let us have it in our Society and in our Section management.

Coöperation and More Coöperation—What It Can Do

As stated, the By-Laws suggest coöperation, coöperating mainly with other engineering groups like local sections of other national societies and local engineering societies, but also with other organizations of whatever kind for the furtherance of objects benefiting the engineering profession or the community at large. Coöperation with other engineering societies or sections, aside from being a necessity in communities where our Sections are too small, lends variety to meetings, helps to secure better papers, and avoids duplication of work in many instances. But mainly it is to be recommended because engineers of different branches should come in closer touch, should know and understand each other better, each other's work and problems and difficulties. They should discuss more the joint interests of our profession, our aims and hopes and ideals. They should plan more for joint work, of which there is plenty.

There is standardization, so far almost exclusively done by individual engineering societies. It seems that a great deal could be done by having national societies coöperate to establish national standards, instead of A.I.E.E. standards, S.A.E. standards, A.S.M.E. standards, and whatever they all may be.

And do not let us stop at the national frontiers. Let us join with foreign engineers to establish international standards. We are learning much just now regarding the lack of international uniformity, when we are doing so much work for the European nations who have different standards, yes, who even have different systems of measurements. Some beginning has been made, and just now the International Aircraft Standards Board in Washington is doing useful work.

But not only for war is such standardization desirable, it is important also in the work of peace. We have entered the group of nations which export industrial products to a large extent. Our weakness in manufacturing is special work; our

strength, quantity manufacture of standardized products. International standardization would be of greater benefit to us than to almost any other nation.

Coöperation with other engineers will also help us to increase and to exert the influence of the engineering profession. Strong local engineering societies, to which are affiliated all the sections of the national societies, are the best guardians of the engineer's local interests. Coöperation with non-engineering organizations will also increase the influence of engineers and will make available to the community their services and advice on subjects on which their knowledge is greater and their judgment better than that of the average citizen.

How far a section or any engineering society should go in taking up subjects not closely related to engineering or the engineering profession, it is of course impossible to advise. When, however, an engineering society takes an official stand, it should be only on a matter affecting the engineer as such, but regardless as to whether it is engineering work or economic and social legislation.

Broadens the Engineer, Brings Him in Touch with Affairs

Hand in hand with coöperation goes the broadening of the engineer. Coöperation widens our horizon, and a wider horizon in turn enables us to coöperate better. I want to make a strong plea for a broader scope of the engineer's interests, for a broader education. I mean not only broader school and college education. I want to plead especially that the engineer, after graduation, continue not only study and interest in engineering subjects other than his own, but also in economic and social questions, which so vitally affect our work. The knowledge we acquire in college is valuable, but the best thing we can take with us from college into after life, as James Bryce once expressed it, is the taste for knowledge. Do not let us lose that, do not let the young man lose it when he comes from college and when he necessarily must specialize to a great extent in order to get a start.

No period in the world's history has been so under the influence of engineering work and development, as the present; during no previous period has the engineer himself depended to such an extent on economic and social conditions as now. Is it then not logical to say that the engineer should and must now be in closer touch with the legislation and administration of country, state, and city than ever before?

The world is moving fast just now. When we are fixing prices of food, of fuel, of raw and partly finished products, when we consider control and even operation of our railroads by our Government, we certainly have adopted economic ideas not in favor heretofore. When the Conference of Organized Labor is addressed by the President of the United States, and when the executive council of this same organized labor files a resolution outlining a foreign policy for the nation and insisting upon participation in the peace conference by labor delegates, certainly changes are taking place in our country.

And with it all, these changes seem but small compared with those across the ocean. Any class of men so vitally affected by economic and labor conditions as the engineers must study these developments; anybody but him who lives in dreamland, must reckon with them. Do not deceive yourselves by thinking that except for the one great revolution the changes going on are not so vital and that things may get back to where they were before. Try to compare today with yesterday. If you can discover a milestone in the past ten or fifteen years ago which indicates conditions as they were, compare and you will realize the journey we have taken. You are so accustomed to plotting curves. Plot, so to speak, your curves of economic and social changes with the abscissa time. See how they changed from past to present and try to divine where they will lead in future.

The question of the standing enjoyed by our profession will solve itself if we but broaden and coöperate. In the past the engineer has specialized, and with ability and strenuous effort he has succeeded in doing great things. But too often it has been someone else who coördinated and directed and interpreted his efforts and who, therefore, received, and perhaps to a considerable degree deserved, the credit for success in an enterprise. I am not one of those who believe that advertising the engineering profession is the panacea for these ills. True, the general public had for a long time misunderstood the engineers' work; it had considered him quite generally a man without imagination. As to the general willingness, however, at this time, to concede the engineer a prominent place, there can be little doubt. The war has furnished all the advertising necessary for the engineer.

The Desired Result Within Reach

It may be felt that I have strayed far from Sections By-Laws, that I have gone roaming into fields rather unconnected with our work as Sections and Sections Committee. But the new by-laws are an expression of modern tendencies; the committees that framed them and the men who passed them in the Council were under their spell, consciously or subconsciously. And as I see our by-laws, they suggest and they encourage more democracy within our Society, coöperation and broader interests, a stronger and more worth-while engineering profession, and service to our country and the world. Certainly when we go dreaming on these subjects there is no limit to our imagination and no measure for the enthusiasm and inspiration which we may derive.

A conference of Ohio engineering societies was held at Columbus January 29. The meeting resulted in the formation of a permanent organization named the Association of Ohio Technical Societies, with Clyde T. Morris, professor of civil engineering of Ohio State University, as president and C. E. Drayer of Cleveland as secretary. All local societies and local sections of the national societies in the state, twelve in all, were represented, except one which has since indicated its desire to be included, so that the representation now includes all.

Resolutions were adopted endorsing the ten cardinal principles adopted by the Committee on Engineering Coöperation at its conference last March; urging local societies to endeavor to have at least one engineer named on any board having to do with the expenditure of public funds where engineering experience would be of assistance; and endorsing the report of the Inter-society Relations Committee of the Cleveland Engineering Society suggesting that the national societies consider as a prerequisite to membership that a candidate show membership in an accredited local society. Employment, participation in civic affairs and statutory regulation of engineering practice were discussed, the last at length.

All delegates seemed to recognize that regulation by law of the practice of engineering is coming, and that if engineers do not recognize this situation and do the lawmaking themselves, somebody else will.

PROBLEMS OF CRANKSHAFT DESIGN

A Paper in Which Mathematical Deductions from Examples from Prevailing Practice Are Utilized to Derive Factors of Safety and Other Specific Values

By OTTO M. BURKHARDT, BUFFALO, N. Y.

GASOLINE engines, of the kind at present produced in large quantities for airplanes and motor vehicles, may turn over at 3000 r.p.m. or faster. The forces necessary to induce and maintain these speeds, as well as other forces closely associated with high speeds, are numerous; but with a particular object in mind, this paper will be confined to the three most important groups of forces—the pressures due to the gaseous mixture, the inertia forces, and the centrifugal forces. The smooth running and the life of an engine depend mainly on these three factors.

The reciprocating masses linked to the crankshaft will be considered as one mass concentrated at one point in the axis of the cylinder. This simplification implies that the inertia forces are, like the gas pressures, acting primarily in the direction of the cylinder axis, a condition that permits arithmetical addition of both groups of forces. To the same category belongs another group of forces which, according to a well-known law, has its origin in the angularity of the connecting rod. The different component forces have been determined in respect to two engines of equal capacity for 24 crank positions. These positions are uniformly spaced at intervals of 30 deg.

TABLE 1 DIMENSIONS AND WEIGHTS FOR ENGINES OF SIMILAR DESIGN

	Six-Cylinder	Twelve-Cylinder
Cylinder bore, in	3.75	3.00
Stroke, in. (=bore × 1.667)	6.25	5.00
Weight of reciprocating parts, lb. (one cylinder)	4.07	2.60
Weight of rotating parts, lb. (one cylinder)	2.40	1.93
Weight of rotating parts, lb. (two cylinders)		3.86

and comprise two revolutions, which constitute one complete cycle in case of four-stroke-cycle engines.

Corresponding components when combined as resultant forces and graphically represented in magnitude and direction, yield irregular characteristic diagrams with which every engine designer should acquaint himself.

As subjects for investigation, medium-size six- and twelve-cylinder engines, both of the same cylinder volume, were chosen. Both engines are supposed to be similar in design and up to the same standard of construction. Some particulars relating to these engines are given in Table 1.

Fig. 1 is a force diagram pertaining to the six-cylinder engine. The concentric circle is a graphical representation of the centrifugal forces acting on the crankpin at a speed of 2700 r.p.m. The combined gas and inertia forces as above referred to are represented by the irregular polygons.

For instance, O-3 of this diagram represents the magnitude and direction of the combined gas and inertia forces if the crankpin is in position 3, that is, 60 deg. from the top dead center. For one complete cycle the different strokes are represented as follows:

Power stroke, by forces O-1 to O-7
Exhaust stroke, by O-7 to O-13
Suction stroke, by O-13 to O-19
Compression stroke, by O-19 to O-1.

To obtain a clear picture of the total forces acting on a crankpin, we must combine both diagrams as follows: O-1 of the polygon with O-1 of the concentric-circle diagram, and so on. This yields the diagram shown in Fig. 2, which represents the magnitude and direction of the resultant forces acting on the crankpin of a six-cylinder vertical engine.

The combined gas and inertia forces for one unit of a twelve-cylinder engine and the corresponding centrifugal forces are diagrammatically represented in Fig. 3. We observe that these forces are much smaller but quite analogous to those given in Fig. 1. The combination of the gas and inertia forces with the centrifugal forces yields the diagram shown in Fig. 4, which represents in magnitude and direction the resultant forces per cylinder acting on the crankpin of a twelve-cylinder engine. It must be borne in mind, however, that in the case of the engine under consideration, two single-cylinder engines are acting on one crankpin. We have, therefore, to superimpose two diagrams so that their vertical axes include an angle of 60 deg., as in Fig. 5. The crank positions 1 to 24 in the diagram are plotted according to the clockwise rotation of the crankshaft. The distinction between the right- and left-hand block of cylinders is made through the indices *R* and *L* by similarly viewing the engine. According to the conventional sequence of firing, we obtain: 1L, 6R, 5L, 2R, 3L, 4R, 6L, 1R, 2L, 5R, 4L, 3R. From this we see that the engine on the right is in phase 420 deg. behind the other, or (what amounts to the same thing) 300 deg. ahead of it. It follows that we must combine force O-1L due to the left-hand engine with force O-11R due to the right-hand engine and so on. Properly carried out for all simultaneous acting forces, this yields a diagram, Fig. 6, representing in magnitude and direction the forces acting on the crankpin of a twelve-cylinder V-type engine.

It is difficult to neutralize by balance weights the effect on the crankpin of the forces shown in Figs. 2 and 6. The reason is that the centrifugal forces involved are due to a mass performing a relative motion. That is to say, the rotating mass of the connecting rod does not rotate truly about its own center but turns relatively to another mass, which turns about a center of its own.

In order to be entirely effective under such circumstances, balance weights would in turn have to perform relative motions. This introduces extra friction and complication. Balance weights for this effect are quite feasible, however, for six-cylinder engines, but they are almost an impossibility for twelves. The diagrams reveal the fact that the forces are smallest in a horizontal direction. This suggests that the oil holes in the crankpin should be placed at right angles to the radial lines through the center of the pin. The preferable direction would be opposite to that of rotation. To prevent the oil from escaping, a labyrinth should be cut in the bushing bearing surface, where the forces are a minimum.

[1] Mathematical Research Engineer, Pierce-Arrow Motor Car Company.

Abstract of paper presented at a meeting of the Engineering Society of Buffalo, Automotive Section, October 24, 1917.

A glance at Figs. 2 and 6 shows that the difference in the loads acting on the crankpin of either engine is not marked. The maximum load in the case of the twelve is 4040 lb., and in the case of the six, 4795 lb. The difference between the two is $18\frac{3}{4}$ per cent of the former. These loads increase approximately as the square of the speed. If then the twelve-cylinder engine runs at 2940 r.p.m., it is subject to the same maximum load as is the six when running at 2700 r.p.m. Mention is made of this because it is generally found in practice that a car with a twelve-cylinder engine is geared so that the engine runs at a slightly higher speed than a six-cylinder engine would be made to run.

The life of a crankshaft bearing depends largely on the magnitude of the mean pressure resulting from the various loads acting during one complete cycle, and this has been found to be 15 per cent smaller with the six than with the twelve. It is an axiom in bearing design that a certain permissible load per unit of bearing surface should not be exceeded. Nevertheless we shall not content ourselves with speaking of maximum or mean loads exclusively, a mistake which is committed by altogether too many engineers who endeavor to design high-speed-engine bearings with a certain specific load as their only guide.

Designers also should not lose sight of the fact that intermittent loads such as are encountered in high-speed internal-combustion engines affect bearings differently than does a steady load. It is well understood that a load acting continually in one direction is likely to cause lubrication difficulties. To what extent a bearing will behave well under the effect of a steady load is shown by an experiment[1] made by Professor Goodman, who states that he has had a journal running for weeks with a surface velocity of 4 ft. per sec. under a steady load of 2 tons (4480 lb.) per sq. in., the journal being kept at a temperature of 110 deg. fahr. by a stream of water forced through it. It is evident that bearing loads of this magnitude are hardly permissible under conditions where the load is subject to frequent and abrupt changes in direction unless an unusual amount of attention is being given to the maintenance of a certain running clearance by frequent adjustments. Therefore it is advisable under ordinary circumstances either to avoid fluctuations in load or to reduce the specific bearing pressure. For instance, the maximum permissible load on crankpins of slow-running stationary gas engines and locomotives is about 1500 lb. per sq. in. of bearing surface.

Furthermore, it is essential for an engineer to bear in mind the well-known fundamental empirical law of fluid motion, namely, that the resistance to sliding is due to the shearing of the fluid film and is consequently a function of the velocity of shearing, the viscosity of the fluid, and the shearing area. This law has proved useful for solving lubrication problems and conforms with the well-known experiments by Beauchamp Tower[2] which showed that the frictional resistance of a journal at a constant temperature is directly proportional to the square root of the rubbing velocity and is independent of the total load.

The laws of friction and carrying power thus far mentioned assume the presence of an oil film of not less than a certain thickness between the journal and the bearing. Without this film no bearing can be safe against undue abrasion. To maintain this much-desired oil film the designer should as far as possible protect bearings from unequal pressure distribution, from abrupt changes in the direction of these pressures, and from an undue rise in temperature.

The pressure distribution, which in most cases is more or less imperfect, depends on the design of the crankshaft, and will be discussed more in particular later. The character of pressures can be determined by means of diagrams. From these diagrams we may derive the mean bearing pressure, which, when multiplied by the circumferential velocity of the journal and the coefficient of friction, represents the work expended in friction.

The rise in temperature may be expressed as a function of the work expended in friction, if we limit ourselves to conditions under which the radiating surface of the bearing and the feed of oil are the same.

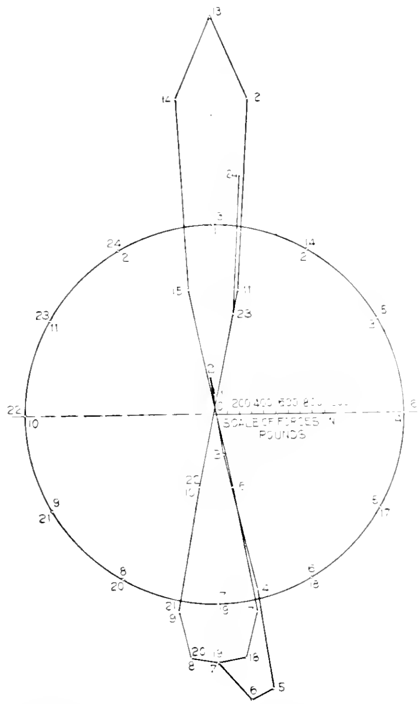

Fig. 1 Centrifugal Forces and Combined Gas and Inertia Forces Acting on Crankpin of Six-Cylinder Engine

The frictional work per square inch of bearing surface is mathematically expressed by:

$$w = \mu \frac{P}{dL} \cdot \frac{d\pi N}{12 \cdot 60} = \mu p v \qquad [1]$$

where

w = work expended in friction per sec. and per sq. in. of bearing surface
μ = coefficient of friction
P = total bearing load, lb.
p = specific bearing load, lb. per sq. in.
d = diameter of shaft, in.
L = length of bearing, in.
N = speed of shaft, rev. per min.
v = circumferential velocity of shaft, ft. per sec.

[1] Unwin, Elements of Machine Design, part 1, p. 243.
[2] Proc. Inst. M. E., 1883 and 1884.

From [1] it follows that

$$pv = \frac{PV}{229L} \qquad [2]$$

According to data gathered from well performing and durable engines it may be stated that the value pv should not exceed 17,000 ft-lb. per sec. This value is far in excess of other similar values. Güldner states that in case of stationary gas engines the maximum limiting value of pv based on experience is about 1500 ft-lb. per sec. for bearings lined with white metal. From this it is evident that a value of 17,000 ft-lb.

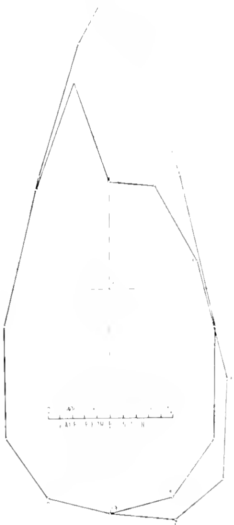

Fig. 2 Combined Centrifugal, Gas and Inertia Forces Acting on Crankpin of Six-Cylinder Engine

per sec. is permissible only in cases where forced lubrication is used.

In this connection it might be suggested that determination of pv values for various lubricating systems would be very desirable.

To apply this pressure-velocity criterion to the two engines under consideration it is necessary to determine the mean pressure of a complete cycle from Figs. 2 and 4. These are 2870 and 1650 lb. for the six and twelve, respectively. Assuming a crankpin diameter of $2\frac{1}{8}$ in. for either engine, we obtain, at 2700 r.p.m., a rubbing velocity of

$$V = \frac{2\frac{1}{8} \times \pi \times 2700}{60 \times 12} = 25.02 \text{ ft. per sec.}$$

With a crankpin length of 2 in. we obtain, in the case of the six,

$$pv = \frac{2870 \times 2700}{229 \times 2} = 16{,}900 \text{ ft-lb. per sec.}$$

With a crankpin length of 1 5/32 in. we obtain, in the case of the twelve,

$$pv = \frac{1650 \times 2700}{229 \times 1\,5/32} = 16{,}825 \text{ ft-lb. per sec.}$$

The total crankpin length of the twelve, if the connecting rods are arranged side by side, should therefore be 2 5/16 in. This is about 15 per cent more than the corresponding length of the six. With equal crankpin diameters for both engines, the crankpin lengths must be proportional to the load. In order to verify this the mean total load acting on the crankpin of a twelve has been determined from the diagram in Fig. 6. As expected, it is 3300 lb., or 15 per cent more than the total load acting on the crankpin of the six.

This and all further comparisons between the six- and twelve-cylinder engines are based on the assumption that both engines are running at the same speed. But, as has been emphasized before, it is general practice to run a twelve-cylinder engine somewhat faster than a six. If this were taken into consideration, the difference between both engines would of course be more pronounced.

Before accepting the crankpin lengths given above as representing the final values, we will ease our minds with regard to the magnitude of the specific bearing pressure. In the case of the six we have a maximum load of 4795 lb. The projected bearing area of a crankpin $2\frac{1}{8}$ in. in diameter and 2 in. long is $4\frac{1}{4}$ sq. in. This gives a specific pressure of 1125 lb.

In the case of the twelve we have a maximum load for each cylinder (taken from Fig. 4) of 2660 lb. and a projected bearing area of $2\frac{1}{8} \times 1\,5/32 = 2.46$ sq. in. This necessitates a

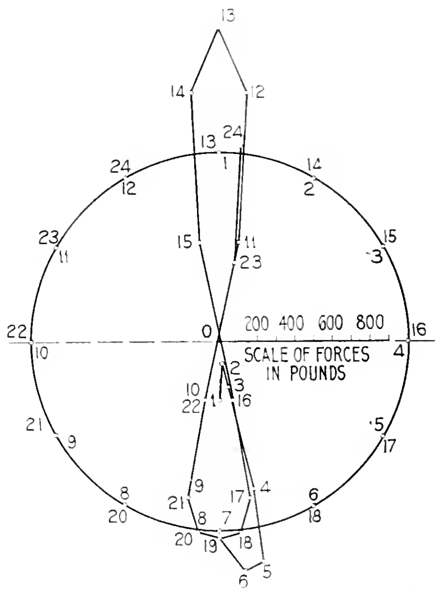

Fig. 3 Centrifugal Forces and Combined Gas and Inertia Forces Due to One Cylinder Acting on Crankpin of Twelve-Cylinder Engine

specific bearing pressure of 1080 lb. The difference between both values is only 4.1 per cent, and both are of such magnitude as to be just about permissible. If the engines are to be used for automobile propulsion, then it may be borne in mind that maximum speed is generally not maintained for any great length of time. The loads above given would represent, then, the exception and not the rule.

Automobile engines, however, are frequently subject to hard usage when long hills are climbed on high gear. Under such conditions the explosive pressures alone determine the loads on the bearings, because the speed of the engine is generally

so low that the inertia and centrifugal forces are negligible. Assuming an explosion pressure of 380 lb. per sq. in. for both engines, we obtain total explosive loads of 4200 and 2690 lb. for the six and the twelve, respectively. In the first case we obtain a specific crankpin pressure of 4200/4.25 = 990 lb., while in the second we obtain 2690/2.46 = 1095 lb. The difference between both engines is here 10.6 per cent in favor of the six. The loads of the two engines due to explosive pressure alone are somewhat smaller than those obtained before at high engine speed.

All forces acting on the crankpin necessitate reactions on the main bearings. The total load on the main bearings also includes the centrifugal forces due to the crankpin and the adjacent crank cheeks. Theoretically, and now even practically, it is a simple matter to attach weights to the crankshaft that will relieve the main bearings on the centrifugal forces. Whether it is an advantage to do so will be presently investigated by means of diagrams.

The forces to be dealt with at first are those relating to the six-cylinder engine resolved into components in a manner as determined for a crankshaft of the seven-bearing type.

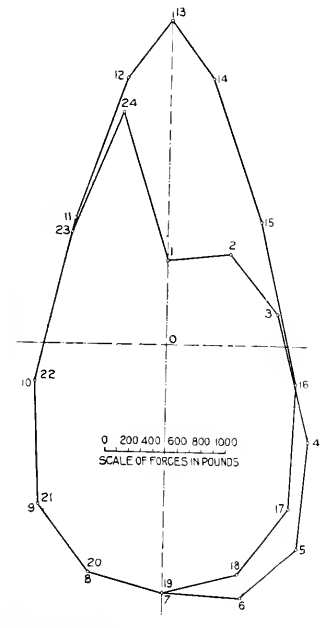

Fig. 4 Combined Centrifugal, Gas and Inertia Forces Due to One Cylinder Acting on Crankpin of Twelve-Cylinder Engine

We are now concerned with two groups of diagrams:

a Main-bearing load for a crankshaft without balance weights: Fig. 7, loads on main bearings I and VII (counting from front of engine); Fig. 8, loads on II, III, V and VI; and Fig. 9, load on IV.

b Main-bearing load for a crankshaft with balance weights: Fig. 10, loads on main bearings I and VII; Fig. 11, loads on II, III, V and VI; and Fig. 12, load on IV.

It is plainly evident from the scale of the diagrams that the balance weights act to reduce considerably the loads on the bearings, but, as already stated, magnitude is not the last word to be said about loads. Sudden fluctuations in the direction of the load are equally, if not more, detrimental to a bearing than the mere magnitude of the loads. Quick changes in the direction of a force acting on a mass are always accompanied by inertia effects. We must expect, therefore, that the journals carrying loads as shown in Figs. 10 to 12 will develop an undesired reciprocating or rocking action. Figs. 7 to 9, however, represent comparatively steady loads. The journals carrying these loads will creep around on the bearing surface, an action in principle like that involved when a planetary gear rolls within an internal gear. This facilitates lubrication, because the lubricant, while adhering to the metal surfaces, is continually wedged in between the two bounding

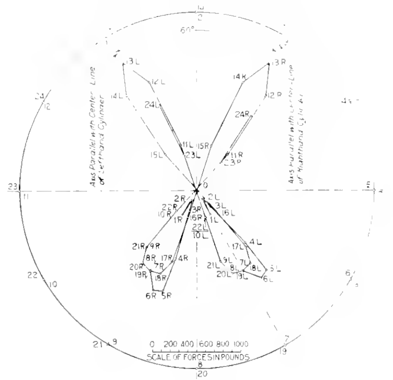

Fig. 5 Centrifugal Forces and Combined Gas and Inertia Forces Due to Two Cylinders Acting on Crankpin of Twelve-Cylinder Engine

surfaces. From this it is seen that beyond pounds of load per bearing there is, so far, nothing to say in favor of balance weights.

The length of the bearings necessary to carry the respective loads safely can be determined by the formula $pv = 17{,}000$ ft-lb. per sec. With a main-bearing diameter of $2\frac{1}{8}$ in. we obtain for 2700 r.p.m. of the engine a circumferential velocity of $v = 25.02$ ft. per sec. The mean loads on the bearings, as obtained from the diagrams, are given in Table 2, together with the necessary bearing lengths, the values of pv and the specific bearing pressures.

In the case of bearings I and VII a liberal amount should be added to the length of the bearing to take care of the loads due to the timing gears and the flywheel, and at least $\frac{1}{4}$ in. should be added to every bearing to allow for fillets. But in spite of this we find that the bearing lengths for the balanced type are entirely too short to hold the requisite oil pressure. If they are lengthened so that they are in conformity with *this* practical consideration we will obtain bearings for a crankshaft *with* balance weights about as long as those for a crankshaft *without* balance weights.

Apart from these analytical considerations it has now become an established fact that the smooth running, life and power of a well-designed engine with a seven-bearing shaft cannot be improved by the addition of balance weights. This is true in spite of the fact that any shaft with balance weights will perform much better on any balancing machine than will its prototype without balance weights. This paradoxical result is easily explained if we bear in mind that a shaft when running in a balancing machine is not subject to the sudden im-

pulses which are a necessary evil inherent to the reciprocating engine. It seems that the best method to make these impulses harmless is to smooth them out by means of the centrifugal forces, which, as we know, are available "free of charge."[3]

It remains now to determine the loads on the main bearings for the twelve-cylinder engine in a manner similar to that which was adhered to in the case of the six. However, since there is not the slightest difference in the procedure, it is permissible to draw conclusions from former results. We must therefore reconcile ourselves with the fact that in all cases the

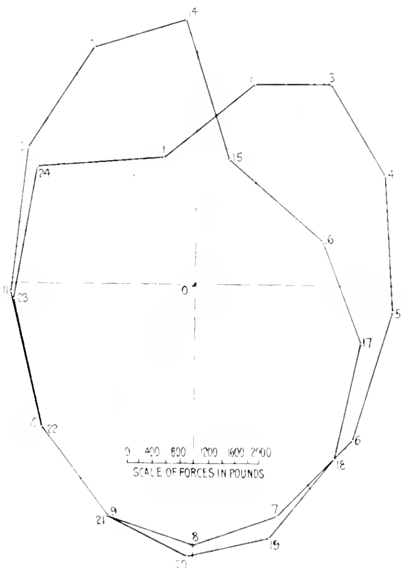

FIG. 6 COMBINED CENTRIFUGAL, GAS AND INERTIA FORCES DUE TO TWO CYLINDERS ACTING ON CRANKPIN OF TWELVE-CYLINDER ENGINE

mean pressure of a complete cycle will be about 15 per cent in excess of the corresponding pressures represented in Figs. 7 to 12. This conclusion is based on the results derived from the force diagrams shown in Figs. 2, 4 and 6. These diagrams show that the mean pressure on the crankpin of a twelve-cylinder engine is 15 per cent larger than that on the crankpin of a six.

In the case of a twelve with two connecting rods mounted side by side on one crankpin the distribution of load over the whole length of the crankpin is not uniform, because the loads on the two connecting rods do not at every instant act with equal intensity. The point of application of the resulting loads given in Fig. 6 is therefore not in the middle of the crankpin, as is the case with the loads given in Fig. 2. The two main bearings adjacent to the crankpin (seven-bearing crankshaft) will not receive at every instant exactly half the loads given in Fig. 6, but alternately the one will receive somewhat more and the other somewhat less than half of the total for well known mechanical reasons.

This rough-and-ready analysis, however, permits the conclusion that the main bearings of a twelve-cylinder engine should be designed to give at least 15 per cent more bearing surface than main bearings which have proved successful for a six-cylinder engine of equal capacity.

In the preceding discussion we have been dealing with various dimensions for crankpins and main bearings. These

TABLE 2 DATA FOR BALANCED AND UNBALANCED CRANKSHAFTS

Bearing number	Type of crankshaft	Mean load	Theoretical bearing length	Value of pv	Mean specific bearing pressure
I, VII	Balanced	774	$\frac{3}{4}$	16,200	645
	Unbalanced	2180	$1\frac{5}{16}$	16,425	677
II, III, V, VI	Balanced	839	$\frac{7}{8}$	15,800	633
	Unbalanced	2190	$1\frac{5}{16}$	16,500	660
IV	Balanced	1520	$1\frac{3}{16}$	16,725	670
	Unbalanced	4350	3	17,040	682

dimensions were chosen according to the dictation of sound engineering. While this method is satisfactory, it is well to verify the results obtained, perhaps in the following manner. Both engines so far spoken about will develop probably a

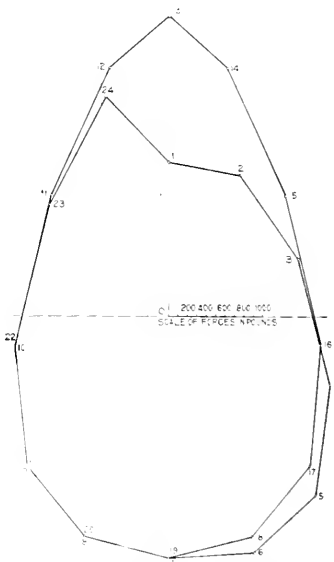

FIG. 7 LOADS ON MAIN BEARINGS NOS. I AND VII OF CRANKSHAFT WITHOUT BALANCE WEIGHTS

maximum torque of about 3000 in-lb. This would correspond to about 48 hp. at 1000 r.p.m. However, the torque on the crankshaft is subject to considerable fluctuation, depending on the number of impulses. This fluctuation, which, of course, has some bearing on the operating smoothness of an engine, was made the subject of many investigations in the early days of the six, and again at the advent of the eight and the twelve. Such investigations have revealed that the multi-cylinder engine, six, eight, twelve, etc., certainly deserves great credit for its smooth torque.

Owing to the small number of impulses, the torque on the crankpin of a six-cylinder engine may at intervals be two and

a half times as large as the torque indicated on the dynamometer. In considering the strength of the crankshaft we must therefore deal with a torque of, say, 7500 in-lb. With a crank radius of $3\frac{1}{8}$ in. this torque results in a tangential force of 2400 lb., acting through the crank cheek on the crankpin as indicated in Fig. 13.

If we at first assume the crank cheeks as being infinitely strong, we can consider the crankpin as a cantilever. With a crankpin length of 2 in., plus half the width of the cheek, the total length of the cantilever will be about $2\frac{1}{2}$ in. The bending moment is, consequently, $2400 \times 2\frac{1}{2} = 6000$ in-lb. The moment of resistance to bending of a $2\frac{1}{8}$-in. diameter cylinder with a 1-in. hole is 0.896 in.^{3} With an elastic limit of 110,000 lb. per sq. in. (chrome-nickel steel) we obtain from these data 16.4 as the factor of safety. Crankpins are further subject to some shearing and bending due to the load acting directly on them, but in the above calculation this has not been taken into consideration. If we allow for these extra stresses we may obtain a final factor of safety of 12, which is not too much for so important a part as a crankshaft.

After this we may now assume the crankpin to be infinitely strong. From this point of view we must expect the crank

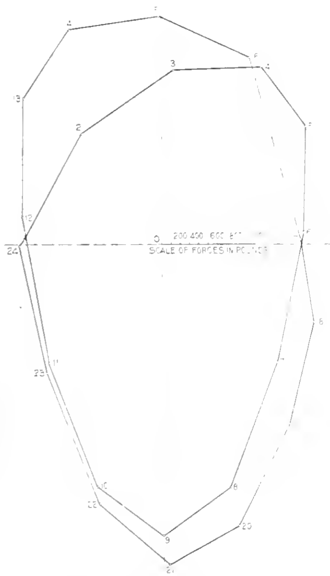

Fig. 8 Loads on Main Bearings II, III, V and VI of Crankshaft Without Balance Weights

cheeks to deflect in a manner as shown in Fig. 13. The twisting moment to be resisted by the cheeks evidently is $2400 \times 3 = 7200$ in-lb. The moment of resistance to torsion of a rectangular section is $2b^2h/9$. The permissible fiber stress in case of twist is about 75 per cent of that permissible for bending. Taking this into consideration, and maintaing a factor of safety of 12, gives the following equation:

$$7200 = 2 \times \frac{0.75 \times 110{,}000}{12} \times \frac{2}{9}\, b^2h$$

From this, taking $h = 2\frac{3}{4}$ in., we obtain the thickness of the cheek b as 0.925 in.; or, to give an even figure, 15/16 in. This small special allowance is desirable because the crank cheeks, like the crankpins, are subject to compound stresses.

In this connection it may be remarked that, as a rule, the crank cheeks are found to be the weakest parts. Fig. 13 and the calculations explain why so many shafts break along the lines marked A B C.

In the case of the twelve-cylinder engine the maximum torque on the crankpin will be only about 50 per cent more than that indicated on the dynamometer. We shall therefore have to deal with a torque of about 4500 in-lb. With a crank radius of $2\frac{1}{2}$ in. we derive from this torque a tangential force of 1800 lb. acting through the crank cheeks on the crankpin. With a crankpin length of 2 5/16 in., plus half the width of the cheek, we have a total length of $2\frac{3}{4}$ in. The bending

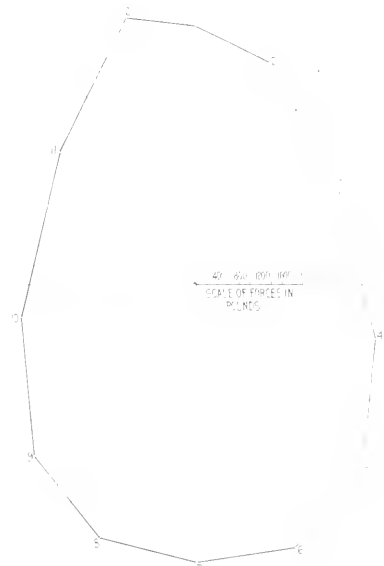

Fig. 9 Loads on Main Bearings IV of Crankshaft Without Balance Weights

moment on the crankpin is therefore $1800 \times 2\frac{3}{4} = 4950$ in-lb. The factor of safety derived from this is 20. The twisting moment in the crank cheeks is $1800 \times 3\ 3/16 = 5740$ in-lb.

The thickness of the cheeks with a factor of safety of 12 we derive as before from the equation:

$$5740 = 2 \times \frac{0.75 \times 110{,}000}{12} \times \frac{2}{9}\, b^2h$$

From this we obtain a cheek thickness of 0.83 in., or, say, $\frac{7}{8}$ in.

In order to compare a three- and seven-bearing shaft it must first of all be observed that the distance between the centers of the two main bearings is about two and a half times as much in the former shaft as in the latter. The transverse deflection of a straight shaft increases as the cube of the distance between the supports. It is evident, therefore, that if other conditions are the same, a three-bearing shaft will deflect up to $(2\frac{1}{2})^3$; that is, nearly sixteen times as much as a seven-bearing shaft.

It is hardly necessary to point out that excessive deflections are certainly not conducive to the operating smoothness of an engine. Not only that, but even the durability of the bearings is impaired, because a deflected shaft will not permit uniform

pressure distribution in the bearing. Any eccentricity of the loading relatively to the middle of the bearing will create a tendency to drive out the oil at one end. This is the reason why bearings that swivel so as to accommodate themselves to any inclination of the journal on account of bending of the shaft are found to be of great advantage. However, as such bearings cannot be applied very well to crankshafts, it is advisable to design crankshafts so that their deflections approach a minimum.

The deflection of a shaft varies inversely as the moment of inertia of its weakest section. In order, then, to hold a three-bearing shaft within the same limit of transverse deflection as may be obtained with a seven-bearing shaft the crankpin diameters of both shafts must be proportioned in the relation

torque in this case is determined by T and by the shortest distance between T and the center of the twisted crankpin, which is denoted by R. From Fig. 15 we find that $R = r + r \sin 30$ or $R = 1.5\ r$. Consequently, in this case, $M = T \times 1.5\ r$. This permits us to draw the conclusion that the torque moments or torsional deflections of a three- and a seven-bearing crankshaft stand to each other in the relation of 1.5 to 1. It must further be mentioned that the twist in a crankpin is a more serious matter than the twist in the main bearings. We must consider that the only way to reduce the vibrations set up by a twist in a crankpin is by an increase in its diameter. The deflections in the main bearings may, however, be minimized by vibration dampers.

The same line of reasoning which we have established in

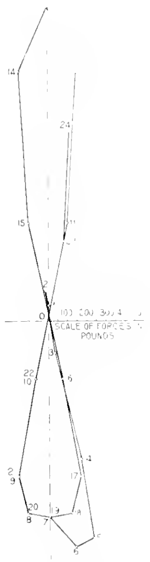

FIG. 10

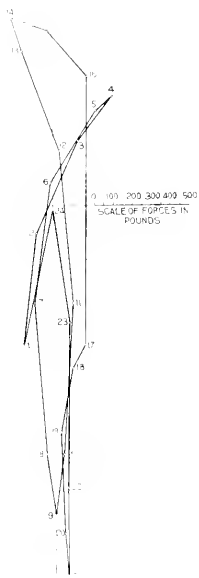

FIG. 11

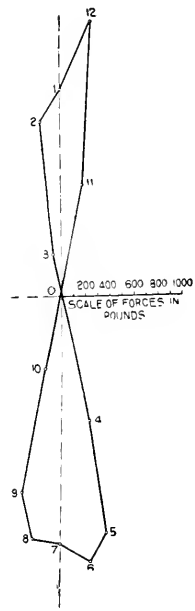

FIG. 12

FIG. 10 LOADS OF MAIN BEARINGS I AND VII. FIG. 11 LOADS ON II, III, V AND VI OF A CRANKSHAFT WITH BALANCE WEIGHTS FIG. 12 LOADS ON IV

of $\sqrt[4]{16}$ to 1, which is as 2 to 1. This necessitates a crankpin diameter of $4\frac{1}{4}$ in. for a three-bearing shaft designed to conform to our premises. For so small an engine as here under consideration this diameter is, of course, prohibitive. At the same time, it is almost prohibitive to use a seven-bearing shaft for a twelve-cylinder automobile engine on account of the excessive length. The only alternative left for the designer of such engines is to sacrifice rigidity.

The torsional deflection of a crankshaft is directly proportional to the torque moment. In a seven-bearing crankshaft a torque moment of the magnitude $M = T \times r$ occurs in the main bearings only. This torque is determined by the tangential force T acting on the crankpin and by the crank radius r, which is one-half the stroke of the engine.

In a three-bearing crankshaft a similar but more intense torque occurs, not only in the main bearings but also in the crankpin, as illustrated in Fig. 14. The momentum of the

connection with the three-bearing shaft must be followed in investigating a four-bearing, six-throw shaft. The distance between two bearings is about 1.75 times as great as in the case of a seven-bearing shaft, and consequently the transverse deflection is about five times larger. With regard to the torque in the crankpins, the same figures as before established apply, except that in this case a smaller number of crankpins are subject to twist.

As excessive transverse deflections must be detrimental to the bearings as well as to the operating smoothness of the engine, it is quite reasonable to expect that balance weights will be an advantage for the latter two types of crankshafts, which are inherently weak. Seven-bearing crankshafts, when well designed, are inherently strong enough so that they cannot be improved through the addition of balance weights. We can predict, therefore, that the use of balance weights will be limited to shafts with a smaller number of bearings than would be desirable from the viewpoint of strength. Balance weights

are like the flywheel, the symbol of some imperfection. If we compare shafts of equal strength we will further find that the weight of a three- or four-bearing, six-throw crankshaft that is properly balanced will by no means be less than that of a seven-bearing shaft.

The total piston displacements of different engines designed with a constant stroke-bore ratio are proportional to the cube of the cylinder bore. For instance, if the bore of an engine is b, and its stroke is $1.667b$, the piston displacement of this engine per cylinder is $(b^2\pi/4)\times 1.667b = 1.309b^3$.

The explosive impulses of different engines are proportional

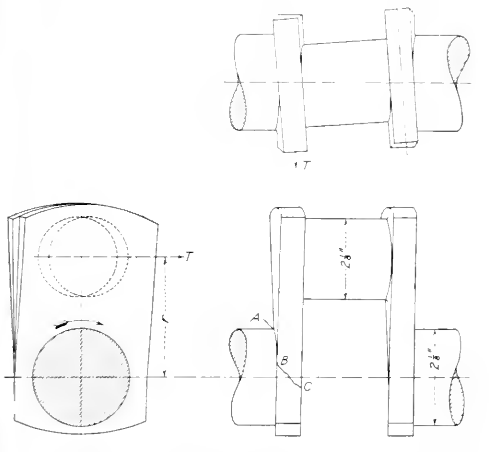

FIG. 13 PART OF CRANKSHAFT ILLUSTRATING DEFLECTION OF CRANK-CHEEKS

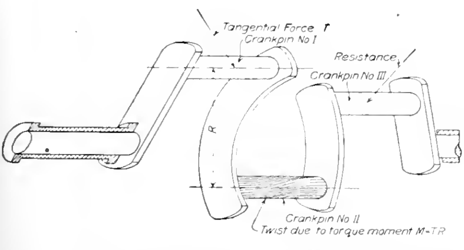

FIG. 14 PART OF CRANKSHAFT ILLUSTRATING TORQUE IN CRANKPIN IN CASE OF THREE- AND FOUR-BEARING SIX-THROW CRANKSHAFTS

to the square of the cylinder bore, providing that the same compression is used throughout. Denoting the bore of a six-cylinder engine with b_6 and that of a twelve-cylinder engine with b_{12}, we find for two engines of equal total piston displacement the following relation:

$$6 \times 1.309 \times b_6^3 = 12 \times 1.309 \times b_{12}^3$$

From this it follows that

$$b_6 = \sqrt[3]{2} \times b_{12} \qquad [3]$$

The explosive impulse E of an engine is proportional to the square of the cylinder bore. Between the explosive impulses of a six- and twelve-cylinder engine the following relation therefore exists:

$$\frac{E_6}{E_{12}} = \frac{b_6^2}{b_{12}^2}$$

When substituting for b_6 the value given in [3], we obtain

$$\frac{E_6}{E_{12}} = \frac{(\sqrt[3]{2})^2 \times b_{12}^2}{b_{12}^2} = \frac{(\sqrt[3]{2})^2}{1}$$

In practice we invariably find that the small-bore engine is working under somewhat higher compression. This results in a higher explosive force per unit of piston area. To give an example, we may assume, for the two types of engines to be compared, that the large-bore, six-cylinder engine may work with a compression pressure of 85 lb. per sq. in., and the small-bore twelve-cylinder engine with one of 90 lb. per sq. in. Substituting this in the above given relation, we obtain

$$\frac{E_6}{E_{12}} = \frac{85}{90} \times \frac{(\sqrt[3]{2})^2}{1} = 1.5 \text{ to } 1$$

From this we learn that for a certain standard of engineering the explosive impulse of a six-cylinder engine is about 1.5 times as large as that of a twelve-cylinder engine of equal total piston displacement.

In conclusion, a few words may be said about lubrication, although this can be considered a problem all by itself. To

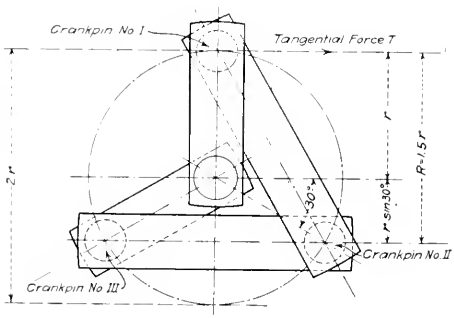

FIG. 15 PART OF CRANKSHAFT SHOWING MAXIMUM LEVERAGE IN CASE OF THREE- AND FOUR-BEARING SIX-THROW CRANKSHAFTS

obtain absolutely satisfactory conditions, the oil delivery to the bearings must be in direct proportion to the work converted into heat by the bearings. We should lay out a series of diagrams, as previously discussed, for different engine speeds and for different power outputs. The values of pv obtained from the various diagrams would give us a clear picture of how the oil delivery should be regulated. Scientific oiling would eliminate scraper rings, and thus permit lighter pistons. It would also eliminate sooted spark plugs, carbonization, preignition, and would permit higher compression.

In the production of aircraft engines, as in all other departments of engineering, it is necessary to effect a reasonable compromise between two conflicting ideals. Standardization leads to a greatly augmented rate of production, but simultaneously makes it correspondingly more difficult to effect the improvements which steadily increasing experience may show to be possible. Cases could readily be cited in which attempts at standardization of machinery on the basis of inadequate experience have proved well nigh ruinous, and the departments concerned were undoubtedly wise in the first instance in leaving open a wide field for invention and improvement. The result of this has been that our best engines are claimed to be two years ahead of the best produced by the enemy, which in true Teutonic fashion have been developed along humdrum lines.—*Engineering*, January 25, 1918.

OFFENSIVE AGAINST THE SUBMARINE

With Annotations to the Suggestions to Inventors Made by the Naval Consulting Board of the United States Regarding the Submarine and Kindred Problems

By JOSEPH A. STEINMETZ, PHILADELPHIA, PA.

Member of the Society

In discussing the tremendous creative zeal of the nation's inventors, especially in suggesting methods of solving the submarine problem, the Honorable Secretary of the Navy recently mentioned that 40,000 separate suggestions, plans, or models of offensive and defensive devices had been submitted to the Naval Consulting Board since the United States entered the war against Germany.

"The idea that the submarine will be overcome by a miraculous invention is not now seriously considered," the Secretary said. "The more intimate knowledge the civilian obtains on this subject, the more convinced he is that the submarine can be conquered by persistently hunting it down by the weapon of which it is most afraid. This is the armed service boat, equipped with all the latest scientific devices and typified in the modern torpedo-boat destroyer. Foreign naval authorities have frankly stated their admiration of the degree of perfection of American designs.

"In regard to the protection of ships against torpedo attack, the undeniable evidence of recent months of submarine activity has demonstrated that the immunity of a vessel depends very largely on its speed and maneuvering ability. There is a possibility that some artificial means of protecting cargo-carrying vessels may be found practicable. In no other field have so many suggestions or so many duplicate inventions been presented to the Board."

The Secretary said that the thought on submarine defense may be subdivided into three groups:

1 Any methods to accomplish the destruction of submarines, involving detection and destruction after detection

2 Means of avoiding submarine attack, involving instructions for merchant vessels, proper handling of vessels, camouflage, smoke screens, and other confidential information known to American naval authorities

3 Protection of ships against torpedo hits.

All the suggestions submitted received careful consideration by the Board, and much valuable aid has been given to various branches of the war service. Many inventions of real merit have been submitted; on the other hand, many proposals have been found to be impractical, largely due to the failure of inventors to inform themselves properly of principles.

To destroy a submarine we must first find it, and therefore the problem of catching, as mentioned, is in its proper order of importance. The difficulty is that the submarine has the greater advantage of lower visibility, approximating invisibility. Before it can be located, it gets home a surprise torpedo. Ninety per cent of the damage and loss comes from that first torpedo, and the necessity of forehand knowledge of the submarine's location, in relation to the approaching ship, bears an equal percentage of importance to the equation.

In certain conditions of sea and weather it is practically impossible, by visual observation, to detect a periscope. Various listening devices are being developed with most encouraging results.

To locate the submarine does not solve the problem of its extinction, and the Secretary is right in recognizing a solution of the menace by direct-gunfire attack. The more guns we mount on our commerce ships and the greater the increase of our swift-destroyer class, the more certainly have we met the submarine. We must blow him out of the water and hunt him from base to base by direct-gunfire attack.

Of late there has been perfected a means of deep-water attack against submerged submarines by the use of the selective-depth bomb. This device, variously charged with from 50 to 500 lb. of TNT or other high explosive, is so arranged that it will detonate at a predetermined depth, estimated to reach the level of the submarine that is lurking below the surface. These depth charges are launched from fast surface craft whose speed carries them away from the eruptive danger following the explosion. The under-water shock is sufficient to break in the hull plating of a submarine in any direction and up to a distance equal to about three times the vertical depth at which the charge explodes.

A well-known type of depth bomb provides a hollow float connected to a thin cable or cord wound around the outside of the explosive container, the depth of detonation being determined by the length of the unwinding cord that pulls the detonator when the mine reaches its selected depth.[1]

Reference is here suggested to the topographical map and contour of the bed of the North Sea, which, contrary to popular supposition, is a comparatively shallow body of water, except for three guts or submarine lanes and the greater deep channel along the Norwegian coast.

The Dogger Bank ridge is but 50 ft. deep, and the average bottom of the North Sea lanes about 200 to 300 ft.; while the deep strip, or main lane on Norway's edge, is 900 ft. deep.

An attack by continuous barrage discharge of depth mines from numerous patrols covering each known submarine lane would check the freedom of these passages with justifiable chance of destroying the enemy U-boats.

The Naval Consulting Board, known so favorably to us all, has worked indefatigably in the consideration of the vast number of suggestions that have been offered. As a guide to help solve the submarine menace the Board issued a bulletin[2] entitled The Submarine and Kindred Problems. As this information is official and helpful to a clear understanding of submarine warfare, offensive and defensive, it would be proper to quote fully from the bulletin.

Protection Against Submarine Attack

This subject, which is occupying the public mind as is no other, divides itself into a number of problems, the most important being the following:

a Means of discovering the approach of a hostile submarine and locating it so as to permit of prompt action for combating its attack

Abstract of paper presented before the Philadelphia Section of The American Society of Mechanical Engineers, December 11, 1917.

[1] U. S. Patent Application Serial No. 161,874.

[2] Bulletin No. 1, July 14, 1917. Copies free by addressing Navy Department.

b Protection of cargo-carrying ships by nets, guards and screens
c Protection through decreasing the visibility of vessels
d Methods of destroying or blinding a hostile submarine.

To these may be added:

e Mines, their use and control
f Torpedoes, use and counter-defense.

Submarines, to operate most effectively, must approach within close range of the vessel which is intended to be torpedoed. The installation of offensive weapons on the merchant marine has increased the necessity for the utmost care being exercised by the submarine commander in remaining unseen by the officers on the vessel to be attacked.

Reports from abroad indicate that in many cases submarines must have remained along certain lanes of travel for periods extending into weeks of waiting with the expectation of torpedoing certain vessels. Under certain favorable conditions, where the waters are less than 200 ft. in depth, the safe limit of descent, a submarine might lie at rest on the bottom, and, if equipped with sensitive listening devices, attempt to detect the approach of a vessel. As soon as this evidence was secured the submarine might come to the surface for a quick observation by means of the periscope and in this manner obtain the proper aim which would be required to register an effective hit.

In case the water is more than 200 ft. in depth, a submarine must be kept in motion to obtain steerage way in order to hold its proper depth of submergence. This speed may not exceed four or five miles per hour, but to remain submerged, and at the same time unobserved, the water must be at least 60 ft. deep.

The latest type of submarine which is being used abroad has a surface speed of at least 17 knots and a submerged speed of probably less than 10 knots. The superior gunfire from the merchantman which has been properly equipped would make it necessary for the submarine commander to obtain his observations, such as would permit accurate aiming of the torpedo, during the very brief interval of time required to come to the surface for observation through the periscope and to again submerge.

If running near the surface, the periscope might be raised, a quick observation taken, and lowered again within 30 seconds. If, however, the submarine is on the surface and hatches uncovered, from one to four minutes will be required to completely submerge, depending upon circumstances.

A submarine of recent type probably has a total radius of action of as much as 8000 miles when traveling at a moderate cruising speed of from 10 to 11 knots, and may remain away from its base for as much as one month, without requiring either fuel or other supplies during this period.

This type of submarine may have as many as 3 periscopes, 2 conning towers, and 2 rapid-fire guns attached to the upper portion of its hull. The vessel is steered by very efficient gyroscopic compasses, which are unaffected by extraneous magnetic or electrical influences.

The *U-53* on her espionage visit to Newport Naval Station and her subsequent torpedoing of a half-dozen friendly and neutral ships within sight of our shore, is a concrete instance of what can be done as to radius of action and what may be again attempted in greater force.

A recent estimate of an allied naval officer determines that the enemy submarines are at surface over 95 per cent of their time when cruising, thus giving opportunity of accidental sinking by night ramming by surface craft as well as for direct surprise attack during fog intervals.

The fact that submarines are submerged so little of the time has developed a simple yet efficient strategy to determine their location. The Allies have used their submarines as feed lures for seagulls, which hover over the hulls tempted by their food, and follow untiringly in the wake of the submerged craft. The gulls, not distinguishing between friend and foe, follow the German submarines patiently, expecting to be fed, and quite innocently declare the location of the enemy boats to the allied patrols.

A general understanding of the capabilities of the modern submarine for offensive operations will make it easier to appreciate the importance of the three problems which follow:

(a) Means for D[illegible]

The Aeroplane. When the conditions [illegible] are favorable, a submarine is readily discernible from an aeroplane flying at a sufficient height, even though the submarine be submerged to a considerable depth.

While aeroplanes have thus been used successfully in the English Channel, they are unable to fly far out to sea where the submarines are now most active. Mother ships for carrying and launching aeroplanes might be used in this connection, but there are only a small number of such ships in operation and the construction of others under present conditions is necessarily a slow process.

The aeroplane promises to play a very serious and important part in sea warfare and torpedo service.

Admiral Fiske, U. S. N., retired, invented some years ago a torpedoplane which is in effect a seaplane carrying on its keel parallel a marine torpedo. The torpedoplane delivers its attack directly in line with the enemy ship. It skims close to the surface and releases the torpedo, which speeds to its target.

The Germans are reported to have used this device successfully in sinking allied surface craft in the North Sea. Private initiative and subscribed money are now reputed to be developing this method into a practical device for our own use.

A similar weapon is described in U. S. Patent No. 1,223,212, covering an aero-marine torpedo which provides for a tubular-shaped charge towed by an aeroplane. The latter, rising in flight, drags a wire towline across the victim ship and, speeding onwards, brings the torpedo into explosive contact.

Aeroplanes have been suggested for use in attacking submarines by trailing under-water deflected bombs.[1]

Location of submerged U-boats by the use of kite observation balloons towed from battleships is one of the later developments of offense. From the high elevation the observer controls an extensive sea area, which permits the discovery of the submarine, the location being announced by wireless and the destroyers and seaplanes with depth bombs called to the attack.

Various sound-recording devices, intended to locate surface vessels, submarines, and even moving torpedoes, are now being carefully tested. Water is an excellent conductor of sound, and the development and improvement of such apparatus offers a promising field for inventive endeavor to those who possess adequate scientific training and laboratory facilities.

Many devices are suggested which depend upon optical means of detection, such as special forms of telescopes and field glasses to be mounted on ships or on scouting vessels. Many special forms of searchlights and projectors have been suggested.

The fact that a moving torpedo leaves in its wake a stream of air bubbles caused by the exhaust air from its propelling engines, offers, under favorable conditions, one means for discovering the approach of a torpedo. This evidence is, however, difficult to detect in a rough sea or at night, and, furthermore, the bubbles do not reach the surface of the water until after the torpedo has traveled toward its target a distance of from 50 to 200 ft.

The warhead torpedo weighs approximately 2500 lb. and travels about 10 to 15 ft. below the surface of the sea at a speed of 25 to 40 miles. We have a record of a British coastal dirigible, while flying in company with a convoy of merchantmen, sighting the track of an oncoming torpedo and a moment later observing the crash of the explosion on the target. An enemy submarine taking advantage of the state of the sea for concealment, had with great daring dived beneath the armed escort and boldly torpedoed her victim. The weather was rough and rapidly getting worse; the dirigible picked up the torpedo wake and followed back along the dead line to its source and located the submarine as a dim green shadow stealthily submerged. The airship hovered over the cigar-shaped form vaguely outlined, released numerous depth bombs, and destroyed the submarine.

[1] U. S. Patent No. 1,218,586.

The dragging of trawls, or nets, by special guard boats, not only with the view of locating submerged submarines but also to sweep up floating and stationary mines, is frequently suggested. Under certain conditions this operation is practicable and effective.

It will be seen that each of the above methods, however useful, has its limitations, and scientists and inventors should apply themselves not only to the task of improving these, but also of finding supplementary methods and devices.

(b) *Protection of Cargo-Carrying Ships by Nets or Screens*

Many designs of such devices are suggested, and most of them are intended to be attached to the hull of the vessel to be protected. Many other suggestions along these lines, and differing only in some of their minor characteristics from the foregoing, have been received by the Board. Up to the present time not one of these proposals involving screens of any kind has received the approval of the Navy Department or of the merchant marine. The principal objections offered to these devices are that they are heavy, difficult to hold in position, unmanageable in a heavy sea, and that they interfere with the speed and with the ability of the vessel to maneuver. The undeniable evidence which has been accumulated during the past few months of submarine activity has demonstrated that the immunity of a vessel to submarine attack is dependent very largely on its speed and also its maneuvering ability. The percentage of vessels having speeds of 15 knots or more which have suffered from submarine attack is very small, while the losses of slow vessels, whose speed is less than that of a submerged submarine, is practically 100 per cent of those attacked. Many of the suggested devices would prevent the launching of lifeboats or rafts from the vessel to be protected. It is barely possible, however, that there may be developed some form of this general plan which will be found practicable. In no other field have so many suggestions or so many duplicate inventions been presented to the Board.

As far back as 1877 a patent was issued containing the following paragraph: "The nature of my invention consists in combining with a vessel a sectional reticulated shield or guard, suspended at a suitable distance from the hull of the ship, and partly or wholly surrounding the same, which shield extends downward a sufficient distance below the water line to arrest a floating torpedo or explode one attached to an attacking vessel."

From that time until the present day many designs have been made, tried, and discarded. It is well known that a shield of sufficient strength and proper design will stop a torpedo, explode it, and render it harmless to the hull of a vessel, if the shield is a sufficient distance away. This distance is generally conceded to be about 30 ft. However, it depends very much upon the strength of a vessel's hull and the details of design made to localize the damage.

It has been the aim of all navies to do away with any form of shield or net protection as, in action, speed and maneuvering qualities are imperative; and generally in wartime a fleet depends for a great part of its tactical value upon its ability rapidly to change its base. Modern naval construction is made to allow torpedo attack without disabling the vessel or preventing her from continuing the fight and eventually reaching her home port. It is known that in the present war battleships have been torpedoed more than once in the same fight, continuing the battle and arriving at the home port at a fair rate of speed.

One of the great shipyards in England is interested in a torpedo-defense pontoon-supported screen that has been favorably noted in the American scientific press. This device is not a part of the ship nor attached to it, but provides a floating spar-like pontoon with a full-length sheet-steel flexible apron. These screens can be towed by the slower ships when moving through mine fields or submarine zones, giving extensive broadside protection. The pontoon screens can be towed as separate units by tugs or trawlers, and the defended ship can move safely forward, protected by these flanking screens.[1]

The author will be glad to send to anyone interested in the further development of this line of defense an illustrated booklet on Submarine Problems and Torpedo Defense.

(c) *Protection Through Invisibility*

The point of lookout on a submarine being close to the water, the position of a vessel at a distance can be determined only by observing its smoke, which floats high in the air. Improved smokeless combustion is therefore desirable. Relative invisibility may also be afforded by methods of painting.

A method of camouflage to suddenly create a fog cloud about a ship is made possible by an arrangement of pipes running along outside the length of the hull, parallel and near to the keel and connected up to the steam boilers. By quickly opening the control valve the steam pressure vents through small openings in the pipe and rises as a fog cloud, instantly enshrouding the ship and confusing the submarine as to aim and direction. This is one of the many patents pending, and is mentioned only to encourage our engineers and inventors to further activities.

It is possible and desirable, if ship-design prejudice could be overcome, to build a low-visibility hull by reducing or eliminating the masts and spars and laying the funnels horizontally near the deck levels, supplementing the draft by further arrangement of blowers.

In the earlier days of the war, submarines were lured into close range by screening the deck guns of merchant steamers and liners and by false-rigging destroyers to simulate helpless sailing craft, but this deceit is increasingly difficult to accomplish as the later U-boats mount powerful long-range guns.

(d) *Destruction and Blinding of the Submarines*

A rapid-fire gun is effective when the submarine is seen within accurate range of the gun; but the target is so small that it is difficult to hit.

The powerful effect of any submarine explosion on all neighboring bodies provides a simple means of destroying or crippling an undersea boat. Once it has been even approximately located, the setting-off of a heavy charge of high explosive, well submerged in the vicinity of the submarine, will bring about this result.

A simple type of selective depth bomb has already been described, and the news items of destruction of enemy submarines by this method of attack give encouraging indication that in this device we have a weapon that spells the doom of the U-boat.[2]

In certain areas, a quantity of heavy, black petroleum or similar substance which will float on the surface of the water has proved an effective means of clouding the optical glass in the periscope's exposed end.

This spreading of oil results, however, in a waste without commensurable result, as a recent device operated from inside the submarine permits of the perfect cleansing of the periscope's outlook glass by projecting against the oil smooch a pressure jet of gasoline or other wash.[3]

Under favorable conditions of wind and position, many vessels have saved themselves from torpedo attack by the production of a smoke screen. This may be formed either by incomplete combustion of the oil used for fuel by most naval vessels, or it may be created by burning chemicals, such as phosphorus and coal tar, or mixtures in which both of these and other materials are used.

[1] Reference is also made to U. S. Patents Nos. 1,219,879 and 1,171,153.

[2] U. S. Patent Application Serial No. 161,874.

[3] U. S. Patent No. 1,222,156.

After hiding itself from the submarine in a cloud of dense smoke, the vessel, if possessed of sufficient speed, may be able by a quick maneuver to change her position and escape before the submarine is able to discharge a torpedo.

The serious fault with this plan has been the accidental condition of windage, for it is apparent that if the wind blows from the direction of the submarine toward the ship she cannot hide quickly in her smoke screen, which is blown away from her.

An improvement of great value meets this need by use of smooth-bore deck guns discharging smoke shells against the submarine, which puts the enemy into a murk screen permitting the merchant ship to escape or, by change of course, to attack the submarine and sink it by gunfire or ramming.[1]

Mines and Torpedoes for Naval Operations

(e) *Mines*

Ever since the first use of gunpowder in the prosecution of war, mines and torpedoes have received great attention, both from the warrior and the inventor. Mines are either fixed or floating. The fixed or stationary submarine mine is fired by contact, electricity, timing device, or fuse. Such mines, which are extensively used by all navies, are rugged in design and may contain large charges of explosives. They are placed in position by especially equipped mine-laying vessels. Such a mine is provided with an anchoring device.

Floating mines differ from fixed mines in that they are unanchored, and, unless guard boats are at hand to warn friendly vessels of their proximity, may be as dangerous to friend as to foe. Such mines must be, according to laws of war, designed to become inoperative within a few hours after being set adrift.

The submarine has been successfully used as a mine layer and can enter defended sea areas and plant mine fields, uncharted and undetected. An elaboration of this function is noted in the possibility of submarines liberating containers of asphyxiating gases or smoke clouds from a position under the enemy battlefleet or surface ships and causing tremendous loss and havoc.

The defense against such surprise being eternal vigilance and full protection to the crews by night and day use of gas masks.[2]

Harbors and waterways are not entirely safe from submarines that may enter submerged below the mine flotation level to avoid contact, and then rise to the surface for observation and bombardment or to release aeroplanes, for distant depredations.

A proposed harbor defense against the enemy submarine awash or surface battlecraft, comprises a method of gas- or smoke-cloud liberation from containers anchored to the bottom and electrically controlled, or detonated, from shore observation stations, thus involving the enemy in a murk or incapacitating gas cloud.

This camouflage mine field could be cheaply created and would be easy to install; and while depriving the enemy of power of observation or fire control, it would yet disclose his position by his military-mast tops rising above the low-hanging cloud and permit the shore batteries to deliver their attack.[3]

(f) *Torpedoes*

The modern submarine torpedo is about 20 in. in diameter and 20 ft. in length, is self-propelled, is not steered by magnetic means, and keeps a fairly accurate course for several thousand yards at an average speed of more than 30 miles an hour. Its weight is approximately a ton and a quarter, and, when traveling at normal speed, it possesses great momentum; in fact, in one case when the high explosive charge in the warhead failed properly to detonate, the body of the torpedo penetrated the steel hull of the ship attacked. Torpedoes are also provided with means to more or less effectively cut through screens, nets, or guards placed in their path.

A torpedo is projected from a submarine or other vessel by means of a special form of tube or gun. A small charge of gunpowder or compressed air is employed to start the torpedo, after which—if of the usual self-propelling type—it is driven through the water by its own compressed-air motor, the air being supplied from a strongly built reservoir within the body of the torpedo itself. The torpedo is kept upon its course by a gyroscope steering mechanism, which is immune to outside magnetic disturbances.

The detonation of the torpedo is accomplished through a mechanism placed within its warhead; and if the torpedo is either abruptly diverted from its course or is checked in its forward motion, the firing device, which is operated by arrested momentum rather than by any form of a projecting firing pin, instantly ignites the heavy charge of explosive contained within the warhead. The explosion, if it takes place within 20 ft. of the vessel, will usually rupture the ship's plating, because of the terrific blow transmitted through the water from the point of the explosion to the ship's side. The depth at which a torpedo travels . . . is usually between 10 and 15 ft. below the surface.

Confining the Submarines

The question as to why submarines are not destroyed before they reach the open sea is a most natural one, and the best answer which it is possible to give, according to the officers of our navy and those of the foreign commissions who have visited this country, is as follows:

The submarine bases are very strongly protected by land batteries, aeroplane observers, and large areas of thickly mined waters extending to such distances that the largest naval gun cannot get within range of the bases. In spite of these protections, there is now going on a continuous attempt on the part of the allied navies to entrap or otherwise defeat the submarines as they emerge from the protected areas. Nets are laid and as promptly removed by the enemy, whose trawlers are in turn attacked by our destroyers. The design of these nets and the detailed arrangement of their fastenings and attachments offer a broad field for invention, but it should be remembered that they must be capable of being used in waters in which there is a tidal current running from two to five miles per hour. Many suggestions for "bottling up" these bases have been offered, but, as will be realized, it is not desirable to publish information which would indicate even in the smallest degree this country's plans.

Ambitious plans have been presented suggesting a great bomb-curtain sea net, strung in sections miles long and pendant 200 ft. deep, to close the North Sea from Scotland to the three-mile limit off the Norway coast. The difficulties are stupendous and the cost would be tremendous, but many important engineers and the scientific and technical press express hope that it will yet be done. This great net would be float-supported, and at the crosswires of the 20- to 30-ft. meshes there would be attached explosive contact bombs to destroy any submarine that would nose in.[1]

Ships and Shipbuilding

Many suggestions are made for ships of unusual form to provide for safety in case of a torpedo or mine exploding near or against the hull. Most of these plans are an elaboration of the usual watertight bulkhead construction now required as structural design for all modern ships.

The multiplicity of watertight compartments in any hull design tends to add to the vessel's safety.

The modern tank steamer used to carry fluid cargoes, such as petroleum products or molasses, is a good example of this design, which has been in general use for many years.

A VOLUME REGULATOR FOR BLAST-FURNACE ENGINES

By L. C. LOEWENSTEIN, WEST LYNN, MASS.

Member of the Society

Blast-furnace operation has attained a high degree of refinement in the proportioning of the various materials composing the charge—the ore, the fuel and the flux. The weight of oxygen—introduced as atmospheric air—per charge has, however, until recently been subject to much uncertainty due primarily to the difficulty of measuring with any degree of accuracy the volume of air delivered. The adjustment of the air supply to the furnace was, therefore, usually made only when the operator found evidence that the furnace was badly overblown or underblown, a process which resulted in a more-or-less variable product and certainly in a reduction in the possible maximum output of the furnace.

With the advent of the centrifugal compressor giving a perfectly steady air blast, the metering of the air supply became more practical and, therefore, more usual. With perfectly definite and uniform charging a definite and uniform weight of air per minute is desirable. Constant-volume governors have been designed on two principles, one by metering the air by means of a venturi meter and the other by using an impact float. The venturi-meter governing has been improved by using a multiple venturi meter in which large pressure drop can be obtained in the throat without a corresponding loss in power. This difference in pressure is used on a mercury pot whose motion up and down is translated to the governing mechanism of the driver of the air compressor. The proper setting of this meter is accomplished by changing the tension of the spring until a scale calibrated in cubic feet of air per minute shows that the desired quantity of air is obtained.

In the impact-float method the air is taken through a conical opening in which is suspended a float, this float moving a horizontal beam about a pivot. The horizontal beam actuates the governing mechanism of the driver of the air compressor. On this horizontal beam is a sliding weight which can be set at calibrated marks representing cubic feet of free air per minute. With the weight set in a definite position a certain definite quantity of air is obtained.

In both of these methods, however, the readings on the calibrated scale are only correct when the initial air conditions are standard, that is, are similar in barometer, temperature and humidity to which the scale has been calibrated. Any change in either the temperature of the inlet air or in the atmospheric barometer or in the humidity of the air, changes the weight of the air metered, and, therefore, its oxygen content. As the blast furnace requires an exact weight of oxygen, the above method of holding constant volume is liable, in extreme cases, to have an error of from 15 to 20 per cent.

A volume corrector is herewith presented which when used in connection with the air-metering device will correct for any changes in temperature, barometer and humidity, so that the air supplied to a blast furnace will, at all times, under any atmospheric conditions, deliver a perfectly definite and predetermined weight of oxygen to the blast furnace. This volume corrector is so designed that it requires only one setting for each correction, that is, one setting for any initial temperature, one setting for any existing barometer and one setting for humidity as usually obtained by the difference of readings on a wet- and dry-bulb thermometer.

THE blast furnace is primarily an apparatus for producing pig iron; but incidentally it may also be regarded as a huge gas producer. The materials fed to it are the iron ore, the fuel (coke), and the fluxes (limestone), which are charged at the top of the furnace or throat; and the air blast, which is blown in near the bottom of the furnace at the tuyeres. The materials discharged from the furnace are pig iron and slag, which are tapped from the bottom or crucible of the furnace, and the gases and dust, which pass out of the top of the furnace. The iron ore in a blast furnace is deoxidized or reduced, for which purpose the furnace is charged with sufficient carbonaceous fuel to do two things: to abstract all the oxygen from the reducible metallic oxides and to furnish enough heat at high enough temperature to melt down to superheated liquids the pig iron and slag—combinations of irreducible metallic oxides—that are formed. The fuel must supply the reducing energy and the melting-down or smelting requirements; the first by action upon the metallic oxides at a red to a white heat and abstracting their oxygen; the second by being burned at the foot of the furnace by the hot-air blast, and there generating the heat and higher temperatures necessary for the smelting down of the materials already reduced.

In a secondary way the blast furnace may also be regarded as a huge gas producer, run by hot forced blast, in which the incombustible portions of the contents are melted down (with a little unburnt carbon) to liquid metal and slag and are run

Abstract of paper presented at the Annual Meeting, December 1917, of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

out beneath, while the gaseous products pass upward through 50 to 100 ft. of burden and escape above. The escaping gases are primarily of the composition of producer gas, with some of its carbonous oxide changed to CO_2 by the oxygen abstracted from the burden; with some CO_2 added from the decomposition of the carbonates of the charge: and with the usual increment of moisture from the charge and volatile matter (if any) from the distillation of the fuel. Hence, the blast furnace is a huge gas producer, giving a rather inferior quality of combustible gas in large quantities, while reducing to metal and slag the burden of iron ore and flux (limestone) which is put in with the fuel. In fact, the unoxidized and combustible ingredients of the escaping gas represent a large part, often the largest part, of the total calorific power of the fuel.

Air Requirements in Blast Furnaces

From the above it can be readily seen that if the charging of a furnace is uniform, it is quite essential to have the amount of air supplied to the furnace also uniform in quantity. The air pressure required for forcing the air through the furnace varies with the condition of the burden or charge. If the particles of ore, fuel, and limestone are large, that is, the spaces between these particles ample, there is a freer passage for the air than if the particles of ore, fuel, and limestone are small and closely packed. Under certain conditions the furnace may require a pressure of, say, 10 to 15 lb. to force a certain quantity of air through it, while under other conditions, when the material in the furnace is tightly packed, a much higher pressure, sometimes as high as 25 to 30 lb., is required to force through the same amount of air.

Air Compressors for Blast Furnaces

It is therefore absolutely necessary that the air compressor be capable of adapting itself automatically to supply a predetermined *weight* of air, corresponding to the charge in the furnace, regardless of the resistance encountered up to a certain prescribed maximum. Usually the limiting air pressure is 30 lb., as this is the maximum pressure the stack itself will withstand with safety.

The expression *weight of air* is used advisedly, because the blast furnace requires a definite weight of oxygen to combine with the carbon in the coke charged to the furnace. In general practice we refer to this definite weight of air (or oxygen) as a "constant volume of air," but this volume must have reference to specific conditions of temperature, barometer and humidity, because any variation of these conditions changes the weight of oxygen contained in a given volume. The standard conditions most commonly referred to are dry air at 60 deg. fahr. temperature and 30 in. barometer. Air under these specified conditions contains, of course, a perfectly definite weight of oxygen per cubic foot.

Reciprocating Engines and Blowers

Up to the advent of the centrifugal compressor, reciprocating compressors were chiefly used for blast-furnace work. The governor of the compressor driver was set to maintain a speed corresponding to the desired quantity of air, the general idea being that each stroke of the compressor represented a practically constant quantity of atmospheric air regardless of the discharge pressure.

The r.p.m. of the reciprocating compressor was, however, but a poor guide as to the weight of air supplied, and it was left to the judgment of the blast-furnace operator as to whether or not the furnace was receiving the proper amount of air. If in his opinion the furnace was receiving too little air, that is, if it was underblown due to the charge in the furnace offering more resistance to air flow than previously, he would call for a higher speed of the reciprocating compressor. Speeding up the driver would then furnish a somewhat greater quantity of air at the higher pressure. If, however, the blast furnace was overblown, the reciprocating compressor was slowed down, and the quantity of air furnished was reduced. This method of operating, however, necessitated a decided change of condition in the furnace before the furnace operator knew that the air supply to the furnace was not correct, and in many cases the furnace got into a very poor condition before the operator changed the air supply and improved conditions.

With the gradual introduction of greater refinements in determining the quantities and the chemical composition of the ore, fuel and flux entering each charge in the blast furnace, the uncertainty in the quantity of air supplied began to stand out more and more as the weakest link in the chain. There was not only the need for a reliable method for measuring the quantity of air, but engineers were asking for apparatus which,

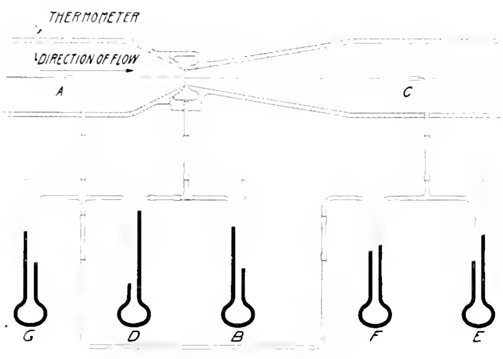

Fig. 1 Venturi Meter

Readings on U tubes *B* and *D* and of the barometer are necessary

while metering the air, would also automatically maintain constant any desired quantity, regardless of the furnace conditions.

[The paper here reviews briefly the underlying theory and formulæ for the flow of gases, and then enters into the following discussion of the commercial methods of regulation of air to the blast furnace.—Editor.]

Commercial Methods for Measuring Air

The commercial methods for measuring air most commonly employed are: (1) The Receiver Method, (2) The Orifice Method, (3) The Pitot Tube, (4) The Venturi Meter, and (5) The Impact-Float Method. Of these the first two methods waste the air they pass, and are therefore suitable only for temporary testing purposes. The other methods allow the air to pass to destination, and may therefore be left continuously in the system.

In the Receiver Method the compressed air is passed into a closed system consisting of a tank and piping of known dimensions and full originally of air of atmospheric pressure and temperature, which conditions are taken as standard. After the compressed air has been flowing into the system for

sufficiently long period, say, half an hour or an hour, the pressure and the temperature are again observed.

In the Orifice Method the compressed air is allowed to discharge into the atmosphere through an orifice of known area and known velocity coefficient. The initial temperature is measured by means of a bare thermometer inserted through the wall of pipe immediately preceding the orifice without well or casing of any kind. The pressures may be observed independently, or, preferably, the pressure drop may be observed by means of an impact tube.

Next to the Receiver Method, the Orifice Method is the most certain and the most reliable method for measuring air, and it is therefore generally recommended as the standard for the calibration of other air-measuring methods. A uniform rate of flow, however, is presupposed, as a pulsating flow, such as comes from reciprocating or positive-pressure compressors, cannot be measured reliably by any method which depends on a density × velocity² observation unless the discharge piping is of an extreme length sufficient to dampen out all pulsations.

The Venturi Meter shown diagrammatically in Fig. 1 consists essentially of a direct and a reversed nozzle placed throat to throat, making a common throat. In general, two U-tubes B and D, or the equivalent, are necessary, one to give the static pressure B in the throat and the other to give the pressure drop D from the main pipe, or high-pressure region, to the throat. It will be noticed that the impact tube A points upstream, so as to include whatever velocity head may exist in the main pipe. After the air passes the throat, the pressure rises again to nearly, but not quite, its original value. This may be demonstrated by the use of impact tube C, pointing upstream, in the pipe beyond the throat. U-tube F communicating with both impact tubes A and C will give directly the pressure loss caused by the insertion of the venturi meter into the system.

The direct nozzle should be short and well rounded, while the reversed nozzle should be well tapered with a half angle of about 4 deg. The inside of the meter must be smoothly finished, and particular care must be taken at the entrance of the U tube into the throat of the meter to avoid all burrs and roughness. Also the impact tube in the main pipe should be small to avoid any eddies and disturbances due to the introduction of the impact tube.

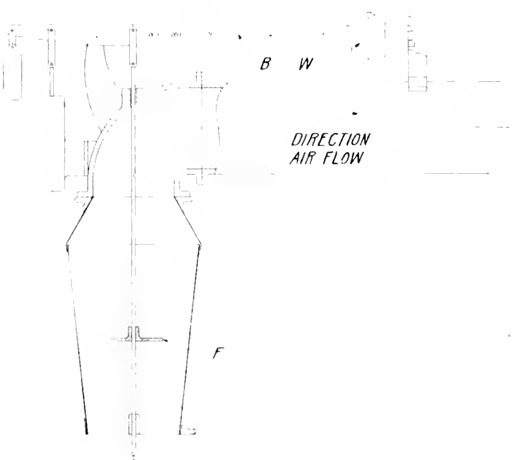

FIG. 2 IMPACT FLOAT AIR METER

The quantity of air may be computed from

$$Q = (423fa \div \sqrt{T_1}) \sqrt{[P_2(P_1 - P_2) - 0.0665\,(P_1 - P_2)^2]} \quad [1]$$

where

Q = cu. ft. of standard air (14.70 barom. and 60 deg. fahr.) per min.
T_1 = absolute temperature in main pipe in deg. fahr.
f = velocity coefficient of throat, usually between 0.95 and 0.99
a = area of throat in sq. in.
P_1 = absolute initial (high) pressure in inches Hg
P_2 = absolute pressure in throat in inches Hg
$P_1 - P_2$ = pressure drop.

In designing a venturi meter for a particular case, the area a is so chosen that the value of $P_1 - P_2$ for the quantity of air most commonly used should be large enough to be read conveniently and with reasonable accuracy and yet not so large as to cause an excessive pressure drop and power loss in the meter.

It is preferable to measure the air before it is compressed, so that P_1 and T_1 are the atmospheric pressure and absolute atmospheric temperature, respectively. A single U-tube like U-tube B in Fig. 1 is then sufficient. The actual pressure P_1 must be obtained from the existing barometer and then P_2 can be computed from the reading $P_1 - P_2$ on the U-tube.

The U-tube can also be calibrated in cubic feet of air per minute instead of indicating only inches of mercury pressure. When so calibrated it can only refer to some standard or average condition of air, and any change in temperature, barometer or humidity will affect the correct reading on such a calibrated scale.

IMPACT-FLOAT METHOD

The Impact-Float Method described previously in a paper by Mr. R. H. Rice before this Society and illustrated in Fig. 2 consists in allowing the air to be metered to impinge on a float F, usually in the form of a disk, suspended vertically in a cone. The air enters the small end of the cone, and its velocity is steadily reduced as it passes up toward the larger end of the cone. The force tending to lift the float, and whatever is attached to it, against gravity consists partly of the direct impact of a part of the air against the float, and partly of the pressure drop caused by the passage of the air through the annulus between the float and the cone in a sort of *vena contracta*. As the float rises in the cone, this force is reduced by the lowered velocity of the air, so that the position of the float in the cone is a function of the quantity of air passing through the cone.

It is desirable, however, for reasons which will appear later in connection with air regulation, to confine the position of the float within narrow limits, regardless of the quantity of air. This is accomplished as shown in Fig. 2 by connecting the float to a horizontal lever or beam B, the force on the float being balanced by a sliding weight W, which can be moved to any part of the beam. The beam is so graduated that the position of the sliding weight on it gives directly the volume of the air entering the cone.

The impact on the float or the momentum of the air is evidently mV, where m is the mass of air impinging on the float per second and V is its velocity. Since for a constant cross-section m is proportional to γV, where γ is density of the air, the impact on the float is proportional to γV^2 or to $m^2 \div \gamma$. Similarly, the pressure drop through the annulus around

the float is $\gamma V^2/2g$, where V is now the velocity in the annulus, and is therefore also proportional to m^2/γ.

When the air flows through the annulus between the float and cone a *vena contracta* obtains whose area varies with each volume of air flowing. On account of this, formulæ for the float force or reaction based on purely mathematical deductions require modification based on experimental results. The slope of the cone and the ratio of float diameter to cone diameter and also the average velocity of the air through the cone in uence the value of this float force. For long cones having a slope of about one inch in five inches and with floats having areas between 50 per cent and 95 per cent of the annulus area and using average velocities through the cone under 100 ft. per sec., the following formula found experimentally will hold:

$$F = 9 \times 10^{-4} Q^2 \gamma \times (A/a^2) \qquad [2]$$

in which

F = total force of float in lb.
Q = cu. ft. of air per min.
γ = density of the air in lb. per cu. ft.
A = float area in sq. ft.
a = annulus area in sq. ft.

until the beam is level, exactly as in the case of the beam on a pair of beam scales. The pointer on the weight W then indicates the amount of air flowing.

Constant-Volume Governing

Of the above-mentioned methods of measuring air in general, only the last two, the Venturi Meter and the Impact Float, are commercially used for regulating the supply of air to blast furnaces. With the advent of the centrifugal compressor a blowing apparatus became available which could be very nicely regulated in respect to holding any constant volume of air supply to the furnace. The centrifugal compressor delivers an absolutely steady stream of air without any pulsations whatever, and the pressure delivered by such a unit varies closely with the square of its speed. Hence, any volume regulation of air need only influence the speed of the driver of the centrifugal compressor. Up to a very short time ago all volume regulation for centrifugal compressors was based upon a calibrated scale for some standard condition of air, usually assumed as dry air at the average temperature and barometer existing at the location of the set. We again emphasize here

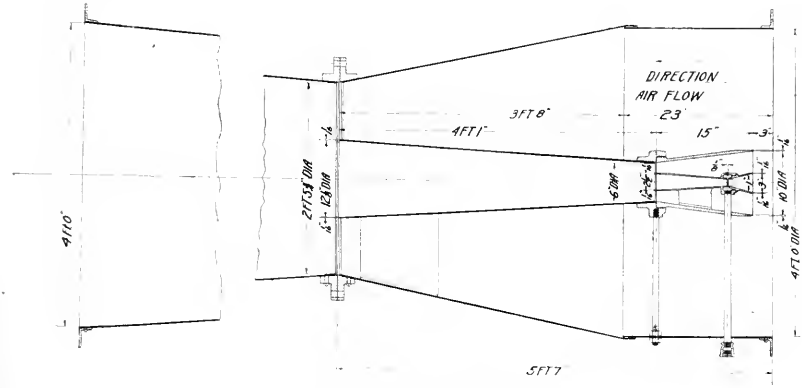

Fig. 3 Triple Venturi Meter

Used for securing a reasonable drop of pressure without excessive power loss

The upward moment of the force F about the fulcrum of the beam (Fig. 2) is counterbalanced partly by the downward moment of the weight of the float and partly by the moment of the sliding weight, which is downward, but may be upward for small volumes of air. In any case, however, the system may be reduced to one having a weightless float and beam, so that the upward moment of the float force F is balanced by the downward moment of the sliding weight W. Since both the weight W and the lever arm of F are fixed, the lever arm of W must be always proportional to the force F, or to M^2/γ, in which M is Q referred to standard conditions of barometer, temperature and humidity, and therefore represents a definite weight of air.

In other words, the beam must have a quadratic scale; that is, the longitudinal distance of the sliding weight from the zero on the beam is four times as great for 20,000 cu. ft. and nine times as great for 30,000 cu. ft. as it is for 10,000 cu. ft. The graduations on the beam are made correct for the average atmospheric conditions of the air at the place where the instrument is to be used.

In metering the air all that is necessary after the beam is calibrated is to move the sliding weight W along the beam

the fact that constant-volume governing is referred to, whereas the object desired is to introduce a constant *weight* of oxygen into the furnace.

The governing of a centrifugal compressor, in order to hold constant volume, requires the use, first, of a meter for measuring the volume of air flow. The necessary qualifications of such a meter, taking into consideration the large quantities of air used in blast-furnace operation, are: (1) It must not waste any of the air it meters; (2) the power consumed in the metering and governing processes must be small, which makes it necessary that the friction losses of air flow through the meter be small; (3) the governor must be sensitive, so that a small change in the quantity of air supplied will be sufficient to actuate the governor.

The Multiple Venturi Meter

An ordinary venturi meter in which the entire quantity of air flowing must be drawn through a sufficiently small throat to give a suitable drop of pressure would involve considerable power loss. To reduce this power loss a multiple venturi has been devised, consisting of a number of concentric venturis.

Referring to Fig. 3, which shows a multiple venturi, a very small part of the total air flow passes through the small or inner venturi. At the throat of this small venturi the largest pressure drop is obtained. A larger quantity of air flows around the inner venturi and through the second venturi, but the bulk of the air flow is around the second and through the third or outer venturi.

Consider a flow of 15,000 cu. ft. of standard air per minute through the triple venturi shown in Fig. 3, the air flowing from right to left as indicated. The air at inlet to the venturi is assumed to be at practically atmospheric pressure and temperature. By the use of Equation [1] and by assuming a probable velocity coefficient $f = 0.95$ for the inner venturi and $f = 0.85$ for the two outer venturis, we can show that the following conditions obtain. Through the inner venturi 175.8 cu. ft. of standard air flows. The pressure at the throat is 22.65 in. Hg, representing a drop of pressure of 7.28 in. Hg. About 1777 cu. ft. of standard air per minute flows through the middle venturi. The drop of pressure from atmosphere (29.93 in. Hg) to the throat of this venturi is 0.73 in. Hg. All the remaining air (13,047 cu. ft.) passes through the outer or third venturi, and the drop of pressure from atmosphere to the throat of this venturi is 0.69 in. Hg.

The loss of power in metering the air through this triple venturi, when passing 15,000 cu. ft. of standard air per minute, can be determined from the loss of pressure between that existing at the entrance to each venturi and the pressure existing at the exit or discharge end of each venturi, taking into account the volume of standard air passing through each. This gives a loss of power of 0.18 hp. for the smaller or inner venturi, 1.06 hp. for the middle venturi and 31.38 hp. for the outer or largest venturi, making a total power loss through the entire triple venturi of 32.62 hp.

The largest drop of pressure in this triple venturi meter occurs in the throat of the inner or smallest venturi. With a flow of 15,000 cu. ft. of standard air per minute, the calculated drop is 7.28 in. Hg (3.57 lb. per sq. in.) pressure. With air entering the meter from atmosphere, the throat pressure will be negative (suction). With varying flow of air through the venturi, the suction at the throat of the inner venturi will also vary; and this varying suction can be used for governing the driver of a centrifugal compressor so as to hold a definite "*constant volume*" of air flow per minute.

THE VENTURI METER CONSTANT-VOLUME GOVERNOR

Fig. 4 shows in a somewhat diagrammatical manner a means for accomplishing this. The pipe leading from the throat of the inner venturi meter is connected to part A representing a mercury-sealed pressure bell, or mercury pot. Suction pressure at the venturi throat is established in the space B between the stationary part of the pot and the upper and movable bell. Variations of pressure in B cause this bell to move up or down. The suction pressure is sealed from atmosphere by a column of mercury surrounding the long sheet-steel skirt or extension of the bell. There is sufficient clearance space between this sheet-steel skirt and the inner and outer shell surrounding it to prevent any frictional contact. The movement of the bell in the mercury pot is transmitted through the links C, D, and E to the steam-valve control to the turbine, thereby opening and closing the number of valves admitting steam to the turbine. An adjustable spring F can be set so as to counterbalance the pull of the bell for any desired volume of air. Handwheels G are used for setting the spring tension, as can be readily understood from the figure. Dashpot H dampens out the oscillations of this gear.

The method of setting for regulation is as follows: Having determined exactly the number of cubic feet of standard air desired per minute, the operator turns the handwheel G and observes the height of the registering mercury column, also attached to the pipe leading from the throat of the inner ven-

FIG. 4 CONSTANT-VOLUME GOVERNOR FOR VENTURI METER. FIG. 5 U-TUBE AND QUANTITY SCALE FOR VENTURI METER

FIG. 4 Uses a mercury pot subjected to the pressure of the throat of the venturi meter shown in Fig. 3 and with adjustments so that it can hold any desired volume as indicated on a calibrated mercury tube shown in Fig. 5.
FIG. 5 Used with a venturi meter as shown in Fig. 3 and with a constant-volume governor as shown in Fig. 4.

turi. This mercury column is not only inscribed in inches of mercury, but is also calibrated in cubic feet of air per minute, as shown in Fig. 5.[1] When the mercury column registers the desired number of cubic feet of standard air per minute, handwheel G is locked. Any change in air flow through the venturi will change the suction in the pipe leading from the throat of the inner venturi to the mercury pot shown in Fig. 4, and also to the gage in Fig. 5. A change of suction on the mercury pot, however, influences the governing mechanism so as to increase the steam admission to the turbine when the suction decreases, or decrease the steam admission to the turbine when the suction increases. By this means constant-volume governing is obtained. Increasing the steam admission to the turbine speeds up the unit, thereby increasing the discharge pressure of the compressor, and vice versa. Equilibrium must be established between the spring tension set by handwheel G and the pressure in the confined space in the mercury pot before the governing mechanism comes to rest.

The calibration of mercury column indicating number of cubic feet of air per minute refers to standard air, that is, air of the average temperature and barometer and humidity for which the unit has been calibrated. Fig. 5 shows a calibrated scale for a normal capacity of 25,000 cu. ft. of air per min., whereas Fig. 3 shows a multiple venturi of a much greater normal capacity, probably 40,000 cu. ft. per min.

The Impact-Float Constant-Volume Governor

The second method for regulating turbo-compressors for blast-furnace work involves the use of the impact oat which was originally conceived as part of the means for constant-volume governing. Fig. 2 shows the impact float suspended in a conical pipe and attached to a beam calibrated in cubic feet of air per minute. If this beam were attached by linkages to the governing mechanism of the driver of a centrifugal compressor, it could be made to take care of its governing.

Fig. 6 shows such a constant-volume governor. Float F is suspended by a vertical rod from beam B. The float is made so it can be heated with a small amount of compressed air introduced through the hollow suspension rod S so as to prevent moisture from condensing and freezing upon the float in winter. The beam is fulcrumed at A and is balanced by counterweight C and movable sliding weight W. Dashpot D prevents too rapid movements or oscillations. Handwheel H on one end of the beam moves the sliding weight W longitudinally along the beam by means of a threaded shaft and nut. The sliding weight can thus be set at any definite position indicating the desired volume of air per minute. Any movement of the beam is transmitted through linkages M, N, O and T to a controlling pilot valve V which will admit steam or oil under pressure to either one or the other side of a piston P. This piston is connected directly to a nest of controlling valves which admit steam to separate groups of turbine nozzles. The turbine governor G is used as a speed-limiting device, so arranged that when the turbine reaches a speed corresponding to that at which the compressor would deliver the maximum permissible pressure (for blast-furnace work usually 30 lb. per sq. in. gage), it moves linkages L, K, and N and thereby influences the governing pilot valve from opening more valves for steam admission. In other words, at this speed it takes the control of the turbine out of the hands of the constant-volume governor.

[1] For Figs. 3, 4 and 5 the author is indebted to the Southwark Foundry and Machine Company.

The important feature of this method of constant-volume governing is the very small pressure drop involved by the air passing through the conical pipe of the meter. The area of the float is so large that a very low velocity of air and an extremely small pressure difference on the two sides of the float is sufficient to afford all the force necessary to move the entire governing mechanism. This fact also makes the governor sensitive to the smallest variation in the quantity of air passing through the compressor.

The force exerted upon the impact float when used as a constant-volume governor can be determined from Equation [2].

It has been found advisable to make the area of such a float equal to

$$A = 700(Q_1/Q)[1/\sqrt{(p\gamma)}] \ldots\ldots\ldots\ldots [3]$$

in which

A = area of float in sq. ft.
Q = correct quantity of cu. ft. of standard air per minute for a definite position of sliding weight
$Q_1 = Q + q$
q = smallest change of volume in cu. ft. of air per min. desired to produce an effect governing
γ = density of air in lb. per cu. ft.
p = mean effective pressure in lb. per sq. in. for which the compressor has been designed.

It will be noticed that the smaller the value of q, the more sensitive will be the governing and the smaller will be the force available for governing purposes. If q is taken reasonably large the governing forces become greater, but the constant-volume governor will be less sensitive. In other words, q is a measure of the per cent of the regulation desired.

When the float is in proper position for the compressor to deliver its normal rating of air against the normal pressure, the annulus area between the float and the cone may be found from the following equation:

$$a = 0.0017Q\sqrt{(\gamma/P_m)} \ldots\ldots\ldots\ldots [4]$$

in which

a = annulus area in sq. ft.
Q = the normal rating of the compressor in cu. ft. of air per min.
P_m = the mean effective pressure corresponding to the normal pressure rating in lb. per sq. in.
γ = density of air in lb. per cu. ft.

It is advisable to make the inlet-pipe diameter for supplying atmosphere air to the constant-volume governor and hence to the compressor of such diameter as to limit the velocity of air to approximately 30 ft. per sec. The constant-volume-

TABLE 1 FLOAT AREAS AND FORCES USED IN IMPACT FLOAT METHOD

Normal rating of unit, cu. ft. of standard air per min.	Quantity of air delivered, cu. ft. per min.	Float area, sq. ft.	Float force, lb.
50,000	45,000	7.43	168
40,000	40,000 35,000	6.87	167 128
30,000	30,000 25,000	4.90	171 118
20,000	22,500 20,000 18,300	3.14	112 89 75

governor cone should extend into an inlet box which would admit air with uniform distribution into the cone. It is therefore advisable to have the inlet box as large as possible.

Table 1 gives an idea of the float forces and float areas employed in practice, the float force having been measured experimentally in each case.

Inaccuracies of Constant-Volume Governors

Both the venturi-meter and the impact-float methods of constant-volume governing applied to centrifugal compressors have resulted in improving the regulation of blast furnaces. Unfortunately, this means of regulating cannot be applied to any other type of air-compressing machinery because all other known types of compressors do not produce an absolutely steady flow of air. The advent of constant-volume governing has eliminated the only remaining guesswork heretofore employed in regulating the air supply to a blast furnace. With

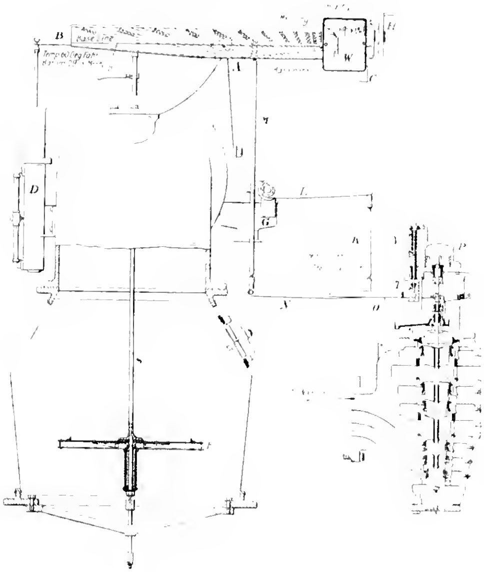

Fig. 6 Volume Corrector

Shown mounted on the beam of a constant volume governor

careful analysis of the iron ore and coke charged to the furnace and a careful weighing of them as they are charged, the amount of oxygen necessary for combustion of the coke and reduction of the iron ore is accurately and easily determined. It is then only necessary in the venturi method to adjust the governing mechanism so that the indicating mercury column shows the desired quantity of atmospheric air per minute; or, in the impact-float method, merely to set the sliding weight on the governing beam to the indicated quantity of atmospheric air desired. In the latter case the weight can be set immediately and the governor will automatically establish the proper air flow, whereas, in the former case, adjustment must be made slowly until the desired air flow is obtained. In both cases, however, if the atmospheric conditions of the inlet air change from the so-called standard or average conditions for which the governors were calibrated, the actual quantity of air delivered, or more correctly, the actual *weight* of oxygen sent to the blast furnace, will vary. This variation may be considerable.

For instance, if the standard air conditions are taken as dry air at 60 deg. fahr. and 29 in. Hg and the governor is calibrated for these conditions, it is possible to conceive a summer condition of 100 deg. fahr. with a barometer of 26 in. and fully saturated air (as on a rainy and stormy day). There is 14 per cent less oxygen per cubic foot of air under these conditions than under standard conditions. In winter, atmospheric air may be at 0 deg. fahr., the air perfectly dry and a barometer of 30 in. Hg. A cubic foot of this air will contain 8 per cent more oxygen than the standard air. It is, therefore, perfectly possible to supply from 8 per cent too much oxygen to 14 per cent too little oxygen to the blast furnace, if regulation is dependent on constant-volume-governor settings of standard or average conditions of atmospheric air.

The Volume Corrector

The main object of this paper is to describe a new instrument named a volume corrector which can be applied to the sliding weight and calibrated scale of an impact-float constant-volume governor for correcting this governor when handling air of any temperature, barometer or humidity. An instrument similar in principle and somewhat similar in construction can also be applied to the indicating mercury column of the venturi meter so as to obtain proper volume correction.

The volume corrector applied to the impact-float constant-volume governor is shown in Fig. 6. The seale beam *B*, instead of having vertical calibration lines for standard conditions of air, has sloping constant-volume lines engraved upon it. The volume corrector proper is mounted on the front of the sliding weight *W*. Fig. 7 is a photographic view of a part of this scale beam with volume corrector mounted on the sliding weight; and Fig. 8 is the same with the hinged door of the volume corrector open, as is the case when the instrument is to be set.

Fig. 9 shows a little more clearly the arrangement of this instrument. There are three milled heads, *A*, *B*, and *C*, provided for adjusting pointers indicating barometer, temperature and humidity. All that is required of the operator is to set these pointers correctly. After obtaining the actual barometer reading from a standard barometer, and the actual temperature of the incoming air, and observing the existing humidity (which is usually done by noting the temperature difference between a wet- and dry-bulb thermometer, pointer *a* is set at the proper barometric reading, pointer *b* at the proper temperature reading, and pointer *c* moved so as to intersect the curve corresponding to the observed temperature difference between the wet- and dry-bulb thermometers.

The movement of each of these pointers influences the final position of the main pointer *P*. This main pointer moves in a vertical direction with respect to the scale on the beam. After the volume corrector is properly set, the sliding weight to which the volume corrector is permanently attached is moved horizontally along the beam until the main pointer *P* intersects the sloping line on the graduated scale designating the proper volume of standard air required. When so set the sliding weight is in the proper position. This permits corrections to be made for variation in temperature, barometer and humidity so that a constant *weight* of oxygen is supplied no matter what the conditions of the atmospheric air. Having determined that the blast furnace requires a definite volume of standard air (dry air at 60 deg. fahr. and 29 in. Hg), the

governor with corrected setting of the sliding weight will deliver the proper amount of actual air which would contain the same *weight* of oxygen as would be contained in the required quantity of standard air.

The amount of oxygen in dry air varies directly as the density of the air. The density of air is directly proportional to the barometric pressure and inversely proportional to the absolute temperature. Expressed symbolically, $\gamma \propto B/T$. As the float force is proportional to M^2/γ, a change in density γ with the governor set to maintain a constant weight M of air per second will cause the governor to change the speed of the compressor until a new weight M_1 is delivered, such that the new value of M_1^2/γ_1 is the same as the original value of M^2/γ. Expressed symbolically, for a given setting of the sliding weight, $M^2 \propto \gamma$, or $M \propto \sqrt{\gamma} \propto \sqrt{(B/T)}$. For moist air the barometer no longer represents the pressure of the air itself, for part of the barometric pressure is due to the vapor pressure in the air. This vapor pressure must therefore be subtracted from the observed barometric pressure in order to get the net air pressure to be used in computing the air density and hence the weight of oxygen per cu. ft. of air. For saturated air (a relative humidity of 100 per cent) the vapor pressure can be read directly from steam tables for the observed atmospheric temperature. If the air is not quite saturated, the relative humidity, or the percentage of the possible maximum of moisture in the air, can be determined in a number of ways; usually, from a dry- and wet-bulb thermometer arrangement. The vapor pressure for a given temperature is proportional to the relative humidity, and this must then be subtracted from the observed barometric pressure in computing the air density.

The graduated scale on the beam of the constant-volume governor was designed by taking a horizontal base line such as was shown in Figs. 6, 7 and 8, and shown schematically in Fig. 10 as AA', and placing thereon the proper calibration for standard air (dry, 60 deg. fahr., 29 in. Hg). The zero on this line gives the position of the sliding weight when the constant-volume governor beam is in equilibrium and no air is flowing. The point B (Fig. 10) represents the position of the sliding weight for 10,000 cu. ft. flow; and point C its position for 20,000 cu. ft. flow, etc. The distance AC is made equal to four times AB. Similarly the distance AD, where D represents the 30,000 cu. ft. point, is made equal to nine times AB. With respect to temperature, the graduations on AA' hold good so long as the prevailing atmospheric temperature is 520 deg. fahr. absolute. When the prevailing temperature is other than 520 deg. fahr. absolute, the relations of the distances AB, AC, AD to each other remain unchanged; but they must all be multiplied or foreshortened by the same ratio. This is accomplished in the following manner:

Referring to Fig. 10, let the line OAB' be perpendicular to the base line AA'; and let OA represent to some scale 520 deg. fahr. absolute, and OB' represent 2080 deg. fahr. absolute to the same scale, so that $OB' = 4\ OA$. Draw $B'C'$ parallel to AA' and CC' parallel to OB'. Also prolong the straight line OB until it intersects the line $B'C'$ in the point P (not shown). The triangles OAB and $OB'P$ being similar, $B'P : AB :: OB' : OA$; or $B'P = 4\ AB$. But $B'C' = AC = 4\ AB$. Therefore $B'P = B'C'$; or P coincides with C'. In other words, the intersection C' of the line CC' with $B'C'$ is a point on the straight line OB.

Now in actual operation when the governor is set to deliver 20,000 cu. ft. of standard air per minute for a temperature of 520 deg. fahr. and should the actual temperature be four times as high, or 2080 deg. fahr. absolute, the governor will, as explained before, with the same setting of the sliding weight, regulate for only 10,000 cu. ft. of standard air per minute, because the density of the air at 2080 deg. fahr. absolute is one-fourth of that at 520 deg. fahr. absolute. The pointer of the sliding weight must under those conditions then read 10,000 cu. ft. without the sliding weight itself being disturbed in any way. In the volume corrector this would be accomplished by pushing up the final pointer along a uniform temperature scale until it reads 2080 deg. fahr. absolute, because the pointer traveling upward would then, as proved above, just intersect the 10,000 cu. ft. line OBC'. It will be noticed that all the

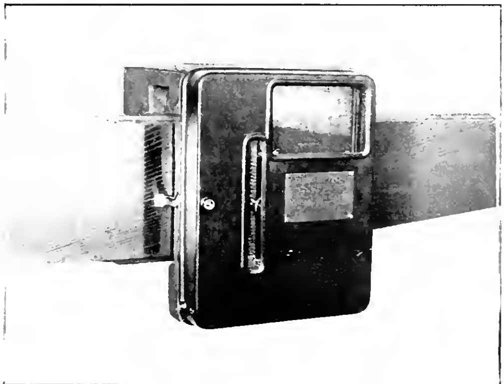

Fig. 7 Photographic View of the Volume Corrector
Front door of casing closed

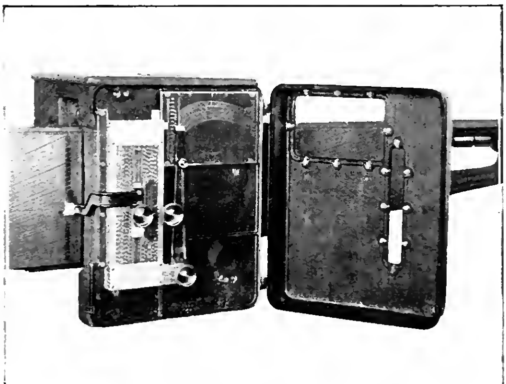

Fig. 8 Photographic View of Volume Corrector
Front door of casing opened

sloping lines representing definite volumes of air per minute meet at O. This would represent the point of absolute zero if the same temperature scale was carried down on the prolongation of the line AB. From the above it can be seen that if the volume corrector be made to carry a temperature scale with the same distances as employed in the engraving of the scale on the beam, and the main pointer P of the volume corrector be made to move vertically up and down the proper distance to this scale, the sliding weight can be set for any observed temperature of atmospheric air so as to deliver the proper volume of air containing the same weight of oxygen as is

contained in the previously calculated necessary volume of air of standard conditions.

Further consideration will show that as far as the density or the square of the volume is concerned, doubling the absolute temperature is equivalent to halving the barometer. In other words, any barometric change can be expressed by an equivalent temperature change. For instance, if 29 in. Hg is taken as the standard barometer and 60 deg. fahr. (520 deg. absolute) as the standard temperature, a change to 28 in. barometer, the temperature remaining at 60 deg. fahr., is equivalent to a change to a temperature of (29 × 520)/28 or 538.6 deg. fahr. absolute (78.6 deg. fahr.) with the barometer remaining at 29 in. Hg. The distance on the barometer scale from 29 in. to 28 in. must therefore equal the distance from 60 deg. fahr. to 78.6 deg. fahr. on the thermometer scale, whereas the correction necessary from 29 in. Hg to 25 in. Hg barometer is equivalent to a change to a temperature of (29 × 520)/25 or 603.2 deg. fahr. absolute (143.2 deg. fahr.) with the barometer remaining at 29 in. Hg. The distance on

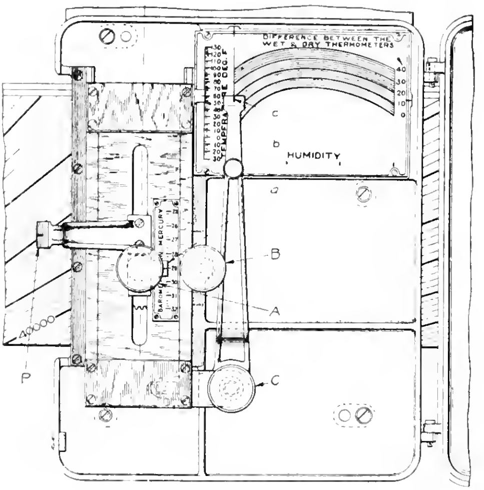

FIG. 9 VIEW OF VOLUME CORRECTOR SHOWING DETAILS

the barometer scale from 29 in. to 25 in. must therefore equal the distance from 60 deg. fahr. to 143.2 deg. fahr.

The barometric scale constructed on the above principle for the volume corrector is evidently a reverse and reciprocal (that is, non-uniform) scale. For constructional reasons, and chiefly to take care of humidity corrections explained later, it is desirable to have this scale uniform without affecting in any way the accuracy of the instrument. This is accomplished in the following manner:

Referring to Fig. 11, which gives a view of the volume corrector shown in Fig. 9 but with some of the front cover plate removed, *A*, *B* and *C* are the pins to which the milled heads *A*, *B* and *C* of Fig. 9 are attached. The main pointer in Fig. 9 is moved up and down in a vertical slot by means of pin *p* in Fig. 11. When the operator moves milled head *A* so that pointer *a* indicates the barometer reading, gearwheel *D* (Fig. 11) rotates about pin *A* because it is meshed into a rack *E* which remains stationary. Motion is given to pin *p* (which is held in a vertical slot) by the slot *S* in gearwheel *D*. This slot is in the form of a cam and so designed that pin *p*, and therefore the main pointer *P*, moves the proper distance vertically. The main pointer will move a less distance vertically when barometer pointer moves from 32 in. to 31 in. than it will when moving from 31 in. to 30 in., and less from 31 in. to 30 in. than it will from 30 in. to 29 in. Therefore, although the barometer scale over which pointer *A* moves has uniform divisions, the actual vertical distance through which the main pointer *P* moves is non-uniform and follows a reciprocal scale.

The setting of temperature is accomplished through milled head *B* which is attached to a plate movable vertically between

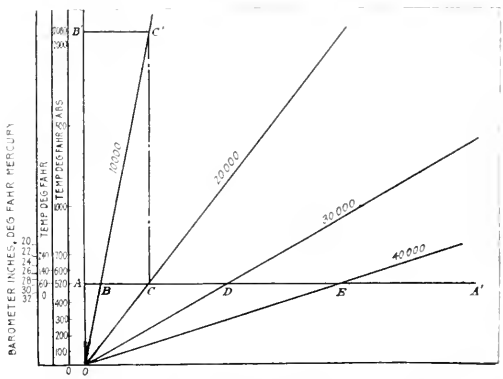

FIG. 10 DIAGRAM ILLUSTRATING CONSTRUCTION OF SCALES ON VOLUME CORRECTOR

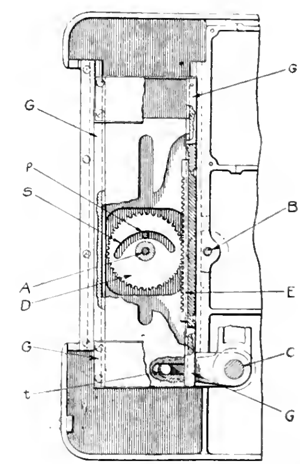

FIG. 11 SECTIONAL VIEW OF VOLUME CORRECTOR

gibs *GG* and which carries with it the rack *E*, gearwheel *D*, and pin *p* with main pointer *P*. Moving *B* up and down does not revolve gearwheel *D* at all (that is, does not disturb the barometer setting), but simply moves main pointer *P* over a temperature scale shown in Fig. 9. Pointer *b* is set opposite the proper temperature reading.

The corrections for humidity in the volume corrector are based upon the following considerations: The barometric-pressure reading as usually observed is equal to the sum of the air pressure plus the vapor pressure. If the air is

saturated, that is, if it contains all the water vapor it is capable of holding without precipitation at the particular temperature, the value of the vapor pressure at the given temperature can be ascertained experimentally or taken from the steam tables. If the degree of saturation or the relative humidity is, say, only 20 per cent or 50 per cent, then the vapor pressure as determined experimentally must be multiplied by 0.20 or 0.50 as the case may be.

The most usual method of ascertaining the relative humidity of the air is by means of a wet- and dry-bulb thermometer arrangement. In its simplest form it consists of two similar thermometers, the bulb of one of which is covered by a wet piece of sponge. If the air is fully saturated no evaporation into it can take place and the two thermometers record the same temperature. When the air is only partly saturated, the evaporation from the wet bulb lowers the thermometer reading; so that the difference in the readings of the wet and dry thermometers can be taken as a measure of the relative humidity of the air. For any combination of relative humidity and atmospheric temperature the vapor pressure is a definite quantity. This vapor pressure must be subtracted from the observed barometer reading in order to give the net or correct air pressure to be used on the barometer scale above described; since it is the density (and therefore the actual pressure) of the air alone that is of importance, and not the density of the mixture of air and water vapor.

It is important to note that the humidity correction in pounds per square inch or in inches of mercury is independent of the actual barometer reading, and depends only on the atmospheric temperature and on the difference between the wet- and dry-bulb thermometer readings (relative humidity). The humidity correction can therefore be made mechanically if the pointer P on the sliding weight is given an additional correction or movement which would be the equivalent amount of a certain subtraction of pressure on the barometric scale equal to the correction for the pressure due to vapor. It is for this reason that it is preferable to make the divisions on the barometric scale uniform, so that, for instance, a half-inch mercury correction would require the same movement no matter at what reading the barometer scale happened to be set. As will be shown later, the volume corrector accomplishes this; therefore, no matter where the barometer pointer a is set, the humidity correction moves the main pointer P on the sliding weight the proper amount. It will also be noticed that the humidity is a function of the atmospheric temperature, that is, when the temperature is high the water vapor in the saturated air is higher than when the temperature is low. In the volume corrector the setting of the temperature pointer b on the temperature scale automatically sets the humidity pointer c to the correct temperature also.

Referring to Fig. 9, the correction for humidity is made by loosening milled head C and swinging pointer c until it intersects or indicates the proper amount of difference in reading between the wet- and dry-bulb thermometer. The movement of the long arm carrying pointer c about the center of milled head C moves pin t attached to a plate carrying gearwheel D, but does not move rack E. Moving gearwheel D vertically up or down rotates D because E is stationary and thereby moves the main pointer P similarly, as heretofore described.

Accurate Constant-Volume Governing

The volume corrector therefore is an instrument which can be set by an operator at the existing barometer, temperature and humidity of the atmospheric air and when so set will permit the setting of the sliding weight on the scale beam in a position so that the constant-volume governor will hold or deliver the correct volume of air which would contain the same weight of oxygen as would be contained in a certain predetermined and desired volume of standard air.

This means that the blast-furnace operator, knowing the chemical compositions of the coke and iron ore and the amounts charged to the furnace in a stated period of time, can determine the exact volume of standard air (dry, 60 deg. fahr., 29 in. Hg) which will contain the proper amount of oxygen necessary for combustion of the coke and reduction of the iron ore in the blast furnace. He need not perform any mathematical calculations as to how much more or how much less air must be supplied when the atmospheric conditions are not those considered standard in order to be sure the blast furnace is receiving at all times its exact and necessary weight of oxygen.

The volume corrector needs resetting every time the operator notices any change in the barometer, temperature or difference between the wet- and dry-bulb thermometer reading in order to be sure of securing the most efficient regulation. The air conditions, however, do not vary rapidly and the practice of inserting in an engine-room log every half hour the steam pressure, r.p.m., vacuum and other information can easily be extended to include readings of the barometer and wet- and dry-bulb instrument. Even with the front cover of the volume corrector closed, transparent places are provided which will permit any one checking or observing these settings. The need of a volume corrector is apparent from the fact that it is possible to have a variation of weight of oxygen delivered to a furnace of 5 to 10 per cent ordinarily and in extreme cases as high as 20 per cent as a result of variations in atmospheric-air conditions, especially as between winter and summer. The gains in quality and quantity of output of a blast furnace obtained even by the former methods of constant-volume governing without volume corrections will be still further improved by the use of constant-volume governing with proper volume corrections.

As a result of representations received from the Advisory Council of the Committee of the Privy Council for Scientific and Industrial Research, and of public meetings held in Glasgow, a joint committee of the Institution of Engineers and Shipbuilders in Scotland, and the West of Scotland Iron and Steel Institute, have prepared a draft memorandum outlining the proposed constitution for a Scottish Engineering, Shipbuilding, and Metallurgical Research Association. The draft memorandum proposes that the objects of the new association should include the following: (1) To promote research and other scientific work in connection with the trades and industries included within the scope of the association; (2) to apply for and accept grants from the Government for the purposes of the association; (3) to establish, form and maintain museums, collections, libraries, etc., and to translate, compile, collect, publish, lend, sell any literature, statistics and information in connection with the trades or industries concerned; (4) to encourage discoveries and inventions in connection with these trades or industries; (5) to establish, promote, coöperate with, receive into union or combine with any other bodies, or persons engaged or interested in similar research work, either in Scotland or elsewhere; and all such subsidiary powers as may be necessary for carrying out the objects of the Association.

REVISION OF BOILER CODE

THE Council of the Society directed that a hearing be conducted in accordance with the recommendation in the Boiler Code that a meeting at which all interested parties may be heard be held at least once in two years to make such revisions as may be found desirable in the Code and to modify the Code as the state of the art advances. The first of these meetings was held at the Society's headquarters in New York, December 8 and 9, 1916.

The Council also directed that the proposed revisions in the Boiler Code be published in THE JOURNAL with the request that they be fully and freely discussed, so as to make it possible for any one to suggest changes before the Rules are brought to the final form and presented to the Council for approval. This has been done, and the revisions are presented below in the form finally proposed for submission to the Council, except as they may be modified by editing without change of sense. Discussions should be mailed to Mr. C. W. Obert, Secretary of the Boiler Code Committee, 29 West 39th Street, New York, N. Y., and they will be presented and acted on by the Boiler Code Committee.

Change letter to the Council to read as follows:

To the Council of THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

GENTLEMEN: Your Committee respectfully submits the following revised report on Rules for the construction of, and allowable working pressures on stationary boilers, this report forming a part of the task that has been assigned to it. Stationary boilers as here considered are land boilers and include portable and traction boilers. The Rules do not apply to boilers which are subject to federal inspection and control, such as marine boilers, boilers of steam locomotives and other self-propelled railroad apparatus.

The primary object of the Rules is to secure safe boilers. The interests of boiler users and manufacturers have been carefully considered and the requirements made such that they will not entail undue hardship by departing too widely from present practice.

The Code applies only in part to certain special forms of boilers such as those of the forced circulation or flash type. New matter has been added to state that the material for boilers of this class shall conform to the requirements of the Code, and that other requirements shall also be met except where they relate to special features of construction made necessary in boilers of this type, and to accessories that are manifestly not needed or used in connection with such boilers, such as water gages, water columns, and gage cocks.

In those states and municipalities which have adopted the Boiler Code, your Committee recommends that all requests for interpretations of the Boiler Code be referred to the state authorities having jurisdiction over such matters. In order to maintain uniformity of practice it is also suggested that the authorities having jurisdiction be requested to submit all inquiries where there is any question of doubt to the Boiler Code Committee. Where there is a question respecting the interpretation of the Code, or where constructions apparently are not covered by the Code, it will be most desirable to have the matter referred to the Boiler Code Committee. Unless this procedure is followed, the aim to obtain uniformity in the application of the Code will be defeated. The Boiler Code Committee desires to coöperate to the limit of its ability in assisting in the application of the Code, and will take pleasure in considering all matters where there is any question of doubt that may be brought before it by the various states and municipalities that adopt the Code.

The Committee does not pass on questions concerning specific designs of boilers or appurtenances thereto.

The specifications given in the Code are the same as or similar to those of the American Society for Testing Materials. The Specifications for Boiler Plate Steel published in the Code (Edition of 1914) were approved and recommended in their modified form, October 9, 1914, by The Association of American Steel Manufacturers, the American Boiler Manufacturers' Association, the National Tubular Boiler Manufacturers' Association, the National Association of Thresher Manufacturers and the representatives present of leading Water Tube Boiler Manufacturers, with whom the Boiler Code Committee was in conference on September 16, 1914, and by whom further modifications were afterwards offered.

The Specifications for Lapwelded and Seamless Boiler Tubes were approved by the Boiler Tube Manufacturers of America, September 25, 1914. Changes made in the specifications published in the original Code have been considered by sub-committees of the American Society for Testing Materials, of The Association of American Steel Manufacturers, and of the Boiler Code Committee in order that coöperation might be secured through these sub-committees making joint recommendations to their respective organizations.

Your Committee recommends that a hearing be held by the Boiler Code Committee at least once in four years at which all interested parties may be heard, in order that such revisions may be made as are found to be desirable, as the state of the art advances.

Yours truly,

JOHN A. STEVENS, *Chairman.*

Wm. H. Boehm, Boiler Insurance
Rolla C. Carpenter, Engineering Research
Frank H. Clark, Railroad Sub-Committee, THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS
Francis W. Dean, Consulting Engineers

PAGE 5

HEADING

Insert above heading of p. 5 the following:

A.S.M.E. Boiler Code

PAGE 7

HEADING

Insert above heading of p. 7 the following:

A.S.M.E. Boiler Code

PAGE 8

PAR. 9. MAKE THE FOLLOWING CHANGE IN PAR. 9:

In second line, omit "and" after the word "headers" and insert a comma.

ALSO ADD A SENTENCE AS FOLLOWS:

Malleable iron may be also used when the maximum allowable working pressure does not exceed 200 lb. per sq. in., and the form and size of the internal cross-section, perpendicular to the longest dimension of the box, shall be such that it will fall within a 7 in. by 7 in. rectangle.

PAR. 12. CHANGE PAR. 12 TO READ AS FOLLOWS:

12 Cast iron shall not be used for nozzles or flanges attached directly to the boiler at any pressure or temperature, nor for boiler and superheater mountings such as connecting pipes, fittings, valves and their bonnets, for steam temperatures of over 450 deg. fahr.

PAR. 13. CHANGE PAR. 13 TO READ AS FOLLOWS:

13 Water-leg and door-frame rings of vertical fire-tube boilers, and of locomotive and other type boilers, shall be of wrought iron or steel, or cast steel of Class A or Class B grade, as designated in the Specifications for Steel Castings. The OG or other flanged construction may be used as a substitute in any case.

PAR. 14. INSERT THE FOLLOWING AT THE BEGINNING OF PAR. 14:

In determining the maximum allowable working pressure.

PAGE 9

PAR. 19. CHANGE PAR. 19 TO READ AS FOLLOWS:

19 The minimum thickness of butt straps shall be as given in Table 1. Intermediate values shall be determined by interpolation. For plate thicknesses exceeding $1\frac{1}{4}$ in., the thickness of the butt straps shall be not less than two-thirds of the thickness of the plate.

TABLE 1. CHANGE VALUE FOR MINIMUM THICKNESS OF BUTT STRAPS FOR 1 IN. THICKNESS OF SHELL PLATES FROM $\frac{3}{4}$ IN. TO $\frac{11}{16}$ IN.

PAGE 10

PAR. 21. MODIFICATION OF THIS PARAGRAPH IS IN THE HANDS OF A SPECIAL SUB-COMMITTEE OF THE BOILER CODE, COMMITTEE ON TUBE SIZES.

PAGE 11

OMIT SUBHEADING UNDER CAPTION: SPECIFICATIONS FOR BOILER PLATE STEEL. ALSO OMIT 7-LINE FOOTNOTE AT BOTTOM OF PAGE.

PAR. 25. MAKE THE FOLLOWING CHANGE IN THE TABLE:

Omit last line of Table which reads as follows:

"Copper.................. Not over 0.05 per cent"

PAGE 12

PAR. 29. MAKE THE FOLLOWING CHANGES IN PAR. 29:

29 *Modifications in Elongation.* *a* For material over [illegible] in. in thickness, a deduction shall be made from the percentage of elongation in Par. 28*a* of four times the thickness in inches in excess of [illegible] in. to a minimum of 20 per cent.

b Strike out the words "or under" from the first line.

PAR. 30. CHANGE PAR. 30 TO READ AS FOLLOWS:

30*a* *Test Specimens.* Tension test specimens shall be taken longitudinally from the bottom of the finished rolled material, and bend test specimens shall be taken transversely from the middle of the top of the finished rolled material. The longitudinal test specimen shall be taken in the direction of the longitudinal axis of the ingot, and the transverse test specimen at right angles to that axis.[1]

b *Bend Test.* The bend test specimen shall bend cold through 180 deg. without cracking on the outside of the bent portion, as follows: For material 1 in. or under in thickness, around a pin the diameter of which is equal to the thickness of the specimen; and for material over 1 in. in thickness, around a pin the diameter of which is equal to twice the thickness of the specimen.

PAR. 31. CHANGE FIRST SECTION OF PAR. 31 TO READ AS FOLLOWS:

31 *Homogeneity Tests.* Homogeneity tests shall be made for fire-box steel on both the broken tension test specimen taken from the lower part of the plate, and on the bend test specimen taken transversely from the middle of the top of the plate. The tests made on the broken tension test specimen shall not show any single seam or cavity more than one-quarter inch long in either of the three fractures obtained in a test of homogeneity, which shall be made as follows:

INSERT A FOOT-NOTE TO READ AS FOLLOWS:

The requirements for the homogeneity tests of the bend test specimen taken transversely from the middle of the top of the plate will be determined by tests, and until such requirements are agreed on by the Boiler Code Committee and published by the A.S.M.E., no homogeneity tests need be made on material taken from the middle of the top of the plate.

PAGE 13

PAR. 33*a*. CHANGE PAR. 33*a* TO READ AS FOLLOWS:

33 *Number of Tests.* *a* One tension and one bend test shall be made from each plate as rolled.

OMIT SUB-HEADING UNDER CAPTION: SPECIFICATIONS FOR REFINED WROUGHT IRON BARS

PAGE 40

OMIT SUB-HEADING UNDER CAPTION: SPECIFICATIONS FOR LAPWELDED AND SEAMLESS BOILER TUBES

PAR. 164. MAKE THE FOLLOWING CHANGE IN PAR. 164*a*:

In the second line, insert a comma after the word "knobbled."

PAR. 167*a*. CHANGE PAR. 167*a* TO READ AS FOLLOWS:

167 *Flange Test.* *a* For tubes not more than 6 in. diameter a test specimen not less than 4 in. in length shall have a flange turned over at right angles to the body of the tube without cracking or showing any flaw. This flange as measured from the outside of the tube shall have a width of from 1/8 in. to 1/2 in., the width between these limits to be not less than 10 per cent of the outside diameter of the tube. For tubes more than 6 in. diameter the flange test is not required.

PAGE 41

PAR. 169. CHANGE PAR. 169 TO READ AS FOLLOWS:

169 *Hydrostatic Tests.* Tubes under 5 in. in diameter shall stand an internal hydrostatic pressure of 1000 lb. per sq. in. and tubes 5 in. in diameter or over, an internal hydrostatic pressure of 800 lb. per sq. in., provided that the fibre stress does not exceed 16,000 lb. per sq. in., in which case the test pressure shall be determined by the following formula:

$$P = \frac{32{,}000}{D} \times t$$

where t is the wall thickness in inches; D is the inside diameter in inches. Lapwelded tubes shall be struck near both ends, while under the test pressure, with a 2 lb. steel hand hammer, the blow to be equivalent to 2 lb. falling 2 ft.

PAGE 42

PAR. 174. CHANGE PAR. 174 TO READ AS FOLLOWS:

174 *Workmanship.* Finished tubes 3½ in. or under in outside diameter shall be circular within 0.02 in. and the mean outside diameter shall not vary more than 0.015 in. from the size ordered. For tubes over 3½ in. in outside diameter, these variations shall not exceed 0.5 per cent of the outside diameter. All tubes shall be carefully gaged with a B.W.G. gage and shall not be less than the gage specified. Tubes on which the standard slot gage, specified, will go on tightly at the thinnest point, will be accepted. The length shall not be less, but may be 0.125 in. more than that ordered.

PAR. 176. CHANGE PAR. 176 TO READ AS FOLLOWS:

176 *Marking.* The name or brand of the manufacturer, the material from which it is made, and the pressure in lb. per sq. in. at which it was tested, shall be legibly stenciled on each tube.

PAGE 44

PAR. 182. MODIFICATION OF THIS PARAGRAPH IS IN THE HANDS OF A SPECIAL SUB-COMMITTEE OF THE BOILER CODE COMMITTEE OF BACK PITCH

PAR. 183. ADD THE FOLLOWING WORDS TO THE END OF PAR. 183:

this distance to be measured from the centers of the rivet holes to the nearest edge.

PAR. 184. CHANGE PAR. 184 TO READ AS FOLLOWS:

184 *Circumferential Joints.* *a* The strength of circumferential joints of boilers, the heads of which are not stayed by tubes or through braces, shall be at least 50 per cent of that required for the longitudinal joints of the same structure.

b When 50 per cent or more of the load which would act on an unstayed solid head of the same diameter as the shell, is relieved by the effect of tubes or through stays, in consequence of the reduction of the area acted on by the pressure and the holding power of the tubes and stays, the strength of the circumferential joints in the shell shall be at least 35 per cent of that required for the longitudinal joints.

c In circumferential joints of horizontal return tubular boilers the shearing strength of the rivets shall be not less than 50 per cent of the full strength of the plate corresponding to the thickness at the joint.

PAGE 45

PAR. 186. CHANGE PAR. 186 TO READ AS FOLLOWS:

186 *Welded Joints.* The ultimate strength of a joint which has been properly welded by the forging process, shall be taken as 28,500 lb. per sq. in., with steel plates having a range in tensile strength of 47,000 to 55,000 lb. per sq. in. Autogenous welding may be used in boilers in cases where the strain is carried by other construction which conforms to the requirements of the Code and where the safety of the structure is not dependent upon the strength of the weld. Autogenous welding shall not be used in place of calking on girth joints.

PAR. 187. CHANGE PAR. 187 TO READ AS FOLLOWS:

187 *Riveted Longitudinal Joints.* The riveted longitudinal joints of a shell or drum which exceeds 36 in. in diameter, shall be of butt and double-strap construction. This rule does not apply to the portion of a boiler shell which is staybolted to the firebox sheet.

PAR. 190. CHANGE PAR. 190 TO READ AS FOLLOWS:

190 In horizontal return tubular boilers with lap joints no course shall be over 12 ft. long. With butt and double strap construction longitudinal joints of any length may be used, provided the tension test specimens are so cut from the plate that their lengthwise direction is parallel with circumferential seams of the boiler and the tests meet the standards prescribed in the specifications for boiler plate steel.

PAGE 46

PAR. 192. ADD NEW SECTION TO PAR. 192 AS FOLLOWS:

c The strength of those ligaments between the tube holes which are subjected to a longitudinal stress shall be at least one-half the required strength of those ligaments which come between the tube holes which are subjected to a circumferential stress.

PAGE 47

PAR. 193. MODIFICATION OF THIS PARAGRAPH IS IN THE HANDS OF A SPECIAL SUB-COMMITTEE OF THE BOILER CODE COMMITTEE ON DIAGONAL LIGAMENTS

PAGE 48

PAR. 194. REPLACE THE FIRST SECTION OF PAR. 194 BY THE FOLLOWING:

194 *Domes.* The longitudinal joint of a dome 24 in. or over in diameter shall be of butt and double-strap construction irrespective of pressure. When the maximum allowable working pressure exceeds 100 lb. per sq. in., the flange of a dome 24 in. or over in diameter shall be double riveted to the boiler shell.

PAGE 49

PAR. 195. ADD AFTER NOTATION FOLLOWING FORMULA:

Where two radii are used the longer shall be taken as the value of L in the formula.

CHANGE THE LAST SENTENCE OF THIS PARAGRAPH TO READ AS FOLLOWS:

When a dished head has a manhole opening, the thickness as found by these Rules shall be increased by not less than $1/8$ in. over that called for by the formula.

PAR. 198. CHANGE PAR. 198 TO READ AS FOLLOWS:

198 A manhole opening in a dished head shall be flanged to a depth of not less than three times the *required* thickuess of the head measured from the outside.

PAGE 50

PAR. 199. ADD TO THE LIST OF VALUES OF C THE FOLLOWING:

$C = 150$ for stays screwed through plates or made a taper fit and having the heads formed on the stays before installing them and not riveted over, said heads being made to have a true bearing on the plate and the diameter of the heads being not less than 1.3 times the diameter of the stays.

REVISE MATTER FOLLOWING LIST OF VALUES OF C TO MAKE IT READ AS FOLLOWS:

If flat boiler plates not less than $3/8$ in. thick are strengthened with doubling plates securely riveted thereto and having a thickness of not less than $2/3$ t, then the value of t in the formula shall be three-quarters of the combined thickness of the boiler plate and doubling plates but not more than one and one-half times the thickness of the boiler plate, and the values of C given above may also be increased 15 per cent.

When two sheets are connected by stays and but one of these sheets requires staying, the value of C is governed by the thickness of the sheet requiring staying.

Acceptable proportions for the ends of through stays are indicated in Fig. 12a.

PAR. 200. CHANGE PAR. 200 TO MAKE IT READ AS FOLLOWS:

200 *Staybolts.* The ends of screwed staybolts shall be riveted over or upset by equivalent process. The outside ends of solid staybolts, 8 in. and less in length, shall be drilled with a hole at least 3-16 in. diameter to a depth extending at least $1/2$ in. beyond the inside of the plates, or hollow staybolts may be used. On boilers having a grate area not exceeding 15 sq. ft., or the equivalent in gas or oil fired boilers, the drilling of staybolts is optional. Solid staybolts over 8 in. long, and flexible staybolts of either the jointed or ball and socket type, need not be drilled. Staybolts used in waterlegs of water-tube boilers shall be hollow or drilled at both ends, irrespective of their length.

PAR. 201. INSERT THE FOLLOWING SIDEHEAD IN THE FIRST LINE:

Structural Reinforcements.

ADD TO PAR. 201 THE FOLLOWING:

If the outstanding legs of the two members are fastened together so that they act as one member in resisting the bending action produced by the load on the rivets attaching the members to the head of the boiler, and provided that the spacing of these rivets attaching the members to the head is approximately uniform, the members may be computed as a single beam uniformly loaded and supported at the points where the through braces are attached.

PAGE 51

PAR. 202. INSERT THE FOLLOWING SIDEHEAD IN THE FIRST LINE:

Stays.

PAR. 203 CHANGE PAR. 203 TO READ AS FOLLOWS:

203*a* The maximum spacing between centers of rivets or between the edges of tube holes and the centers of rivets attaching the crowfeet of braces to the braced surface, shall be determined by the formula in Par. 199, using 135 for the value of C.

b The maximum distance between the edges of tube holes and the centers of other types of stays shall be determined by the formula in Par. 199, using the value of C given in Par. 199 which applies to the thickness of plate and type of stay used.

c The maximum spacing between the inner surface of the shell and lines parallel to the surface of the shell passing through the centers of the rivets attaching the crowfeet of braces to the head, shall be determined by the formula in Par. 199, using 175 for the value of C.

d The maximum distance between the inner surface of the shell and the centers of braces of other types shall be determined by the formula in Par. 199, using a value of C equal to 1.3 times that value of C in Par. 199 which applies to the thickness of plate and type of stay as therein specified.

e In applying these rules and those in Par. 199 to a head or plate having a manhole or reinforced opening, the spacing applies only to the plate around the opening and not across the opening.

UNDER TABLE 3 INSERT:

For the application of Pars. 205, 206 and 207, see Appendix (Par. . . .) (illustrations in Fig. 31).

PAR. 212. CHANGE PAR. 212 TO READ AS FOLLOWS:

212*a* The maximum allowable working pressure for any curved stayed surface subject to internal pressure shall be obtained by the two following methods, and the minimum value obtained shall be used:

First, the maximum allowable working pressure shall be computed without allowing for the holding power of the stays, due allowance being made for the weakening effect of the holes for the stays. To this pressure there shall be added the pressure secured by the formula for braced and stayed surfaces given in Par. 199 using 70 for the value of C.

Second, the maximum allowable working pressure shall be computed without allowing for the holding power of the stays, due allowance being made for the weakening effect of the hole for the stay. To this pressure there shall be added the pressure corresponding to the strength of the stays for the stresses given in Table 4, each stay being assumed to resist the steam pressure acting on the full area of the external surface supported by the stay.

b The maximum allowable working pressure for a stayed wrapper sheet of a locomotive type boiler shall be determined by the first method given above and by the method which follows and the minimum value obtained shall be used:

$$P = \frac{11{,}000tE}{R - \frac{s}{2\Sigma \sin \alpha}}$$

in which

α	Angle any crown stay makes with vertical axis of boiler
$\Sigma \sin \alpha$	Summated value of α for all crown stays considered in one transverse plane and on one side of vertical axis of boiler
s	Transverse spacing (in.) of crown stays in crown sheet
E	Minimum efficiency of wrapper sheet through joints or stay holes
t	Required thickness of wrapper sheet (in.)
R	Radius of wrapper sheet (in.)
P	Working pressure of boiler, lb. per sq. in.
11,000	Allowable stress, lb. per sq. in.

c An internal cylindrical furnace which requires staying shall be stayed as a flat surface as indicated in Table 3, except that the pitch may be increased to p_1 as provided in the following formula:

$$p_1 = p\sqrt{\frac{Pt}{PR - 2{,}000t}}$$

in which p, P, R, and t are the same as in Par. 199.

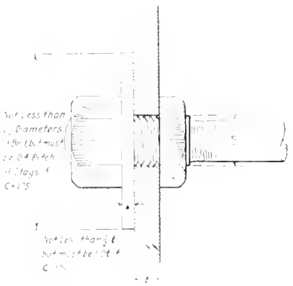

FIG. 12A ACCEPTABLE PROPORTIONS FOR ENDS OF THROUGH STAYS

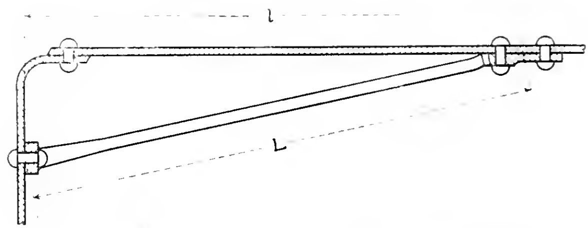

FIG. 15 MEASUREMENTS FOR DETERMINING STRESSES IN DIAGONAL STAYS

PAR. 214. CHANGE PAR. 214 TO MAKE IT READ AS FOLLOWS:

214 *Areas of Segments of Heads to be stayed.* The area of a segment of a head to be stayed shall be the area enclosed by lines drawn 2 in. from the tubes and a distance d from the shell as shown in Figs. 13 and 14. The value of d used shall be the larger of the following values but not less than 3 in.

(1) d = the outer radius of the flange, not exceeding 8 times the thickness of the head

(2) $d = \frac{5t}{\sqrt{P}}$

Where d = unstayed distance from shell in inches
t = thickness of head in sixteenths of an inch
P = maximum allowable working pressure in lb. per sq. in.

(NOTE. DIMENSIONS IN FIGS. 13 AND 14 NOW MARKED 3" TO BE CHANGED TO d).

PAR. 215. CHANGE PAR. 215 TO MAKE IT READ AS FOLLOWS:

215 When the heads of drums of water tube boilers are 30 in. or less in diameter and the tube plate is stiffened by flanged ribs or gussets, no stays need be used if a hydrostatic test to destruction of a boiler or unit section built in accordance with the construction, shows that the factor of safety is at least five.

PAR. 216. CHANGE PAR. 216 TO READ AS FOLLOWS:

216 Stays shall be used in the tube sheets of a fire-tube boiler if the distance between the edges of the tube holes exceeds the maximum pitch of staybolts for the corresponding plate thickness and pressure given in Table 3. That part of the tube sheet which comes between the tubes and the shell need not be stayed, if the nearest tangent common to two tube holes when measured on any radius of the tube sheet that intersects the tangent between the holes, does not exceed this maximum pitch by more than 3 in. The tube holes to which a common tangent may be drawn in applying this rule shall not be at a greater distance from edge to edge than the maximum pitch referred to.

PAGE 54

PAR. 218. INSERT IN FOURTH LINE BEFORE WORD "THICKNESS," THE WORD "REQUIRED."

ADD TO PAR. 218 THE FOLLOWING:

The distance in the clear between the bodies of the braces, or of the inside braces where more than two are used, shall not be less than 10 in. at any point.

PAR. 220. CHANGE PAR. 220 TO READ AS FOLLOWS:

220*a* The full pitch dimensions of the stays shall be employed in determining the area to be supported by a stay, and the area occupied by the stay, shall be deducted therefrom to obtain the net area. The product of the net area in square inches by the maximum allowable working pressure in lb. per sq. in., gives the load to be supported by the stay.

b Where stays come near bounding surfaces and special allowances are made for the spacing, the load to be carried by such stays shall be determined by neglecting the added area provided for by these special allowances. For example, if the minimum pitch by Table 3 would make a staybolt come 6 in. from the edge of the plate and a special allowance would make it come 7 in., the distance of 6 in. should be used in computing the load to be carried.

TABLE 4 MAXIMUM ALLOWABLE STRESSES FOR STAYS AND STAYBOLTS

Description of Stays	Stresses lb. per sq. in. For lengths between supports not exceeding 120 diameters	Stresses lb. per sq. in. For lengths between supports exceeding 120 diameters
a Unwelded or flexible stays less than twenty diameters long screwed through plates with ends riveted over	7,500	....
b Hollow steel stays less than 20 diameters long, screwed through plates with ends riveted over		.....
c Unwelded stays and unwelded portions of welded stays, except as specified in line *a* and line *e*	9,500	8,500
d Steel through stays exceeding 1½ in. diameter	10,400	9,000
e Welded portions of stays	6,000	6,000

c The maximum allowable stress per square inch at point of least net cross-sectional area of stays and staybolts shall be given in Table 4. In determining the net cross-sectional area of drilled or hollow staybolts, the cross-sectional area of the hole shall be deducted.

d The length of the stay between supports shall be measured from the inner faces of the stayed plates. The stresses are based on tension only. For computing stresses in diagonal stays, see Pars. 221 and 222.

TABLE 4. ADD TO TABLE 4 SO THAT IT WILL READ AS ABOVE:

PAGE 55

PAR. 221. REPLACE FIG. 15 BY REVISED CUT.

PAR. 223. CHANGE PAR. 223 TO READ AS FOLLOWS:

223 ***Design of Braces and Brace Connections.*** All rivet and pin holes shall conform to the requirements in Par. 253 and the pins shall be made a neat fit. To determine the sizes that shall be used proceed as follows:

1. Determine the "required cross-sectional area of the brace" by first computing the total load to be carried by the brace, and dividing the total load by the value of allowable stress for unwelded stays given in Table 4.
2. Design the body of the brace so that the cross-sectional area shall be at least equal to the "required cross-sectional area of the brace" for unwelded braces. Where the braces are welded, the cross-sectional area at the weld shall be at least as great as that computed for a stress of 6000 lb. per sq. in. (see Table 4).
3. Make the area of pins to resist double shear at least three-quarters of the "required cross-sectional area of the brace."
4. Make the combined cross-section of the eye at the side of the pin (in crowfoot braces) at least 25 per cent greater than the "required cross-sectional area of the brace."
5. Make the cross-sectional areas through the blades of diagonal braces where attached to the shell of the boiler at least equal to the required rivet section; that is, at least equal to one and one-quarter times the "required cross-sectional area of the brace."
6. Design each branch of a crowfoot to carry two-thirds the total load on the brace.
7. Make the net sectional areas through the sides of the crowfoot, tee irons, or similar fastenings at the rivet holes at least equal to the required rivet section, that is, at least equal to one and one-quarter times the "reqired cross-sectional area of the brace."
8. Make the combined cross-sectional area of the rivets at each end of the brace at least one and one-quarter times the "required cross-sectional area of the brace."

PAGE 58

PAR. 231. CHANGE PAR. 231 TO MAKE IT READ AS FOLLOWS:

231 *Maximum Allowable Working Pressure on Truncated Cones.* *a.* Upper combustion chambers of vertical submerged tubular boilers made in the shape of a frustum of a cone, when not over 38 in. diameter at the large end, may be used without stays if computed by the rule for plain cylindrical furnaces (Par. 239) making D in the formula equal to the diameter at the large end; provided that the longitudinal joint conforms to the requirements of Par. 239.

b. When over 38 in. in diameter at the large end, that portion which is over 30 in. in diameter shall be fully supported by staybolts or gussets to conform to the provisions for staying flat surfaces. In this case the top row of staybolts shall be at a point where the cone top is 30 in. or less in diameter.

In calculating the pressure permissible on the unstayed portion of the cone, the vertical distance between the horizontal planes passing through the centers of the rivets at the cone top, and through the center of the top row of staybolts shall be used as L in Par. 239, and D in that paragraph shall be the inside diameter at the center of the top row of staybolts.

PAGE 60

PAR. 234. UNDER "WHERE" CHANGE DERIVATION OF D TO READ:

D = least horizontal distance between tube centers on a horizontal row, in.

IMMEDIATELY BELOW THE DERIVATION OF LETTERS INSERT:

Where tubes are staggered the vertical distance between the center lines of tubes in adjacent rows must be not less than $\frac{1}{2}\sqrt{2dD + d^2}$

PAGE 61

PAR. 239. CHANGE FIRST SECTION OF PAR. 239 TO READ AS FOLLOWS:

239 *Plain Circular Furnaces.* Unstayed furnaces *more than 18 in. diameter* when riveted or of seamless construction, or such furnaces when lapwelded by the forging process, shall have walls not less than 5/16 in. thick. The maximum allowable working pressure for such furnaces shall be determined by one or the other of the following formulae:

MAKE DEFINITION OF L READ AS FOLLOWS:

L = total length of furnace between centers of head rivet seams (not length of a section), in.

INSERT AFTER THE FORMULA AND JUST PRECEDING THE EXAMPLE IN PAR. 239, THE FOLLOWING, ELIMINATING THE PRESENT SENTENCE:

Where the furnace has a riveted logitudinal joint, it may be of the lap type for inside diameters not exceeding 36 in. for furnaces 36 in. or less in height or length, and for inside diameters not exceeding 30 in., irrespective of the height or length. Otherwise butt and strap construction shall be used. The efficiency of the joint shall be greater than:

$$\frac{P \times D}{1250 \times T}$$

PAGE 64

PAR. 245. CHANGE PAR. 245 TO READ AS FOLLOWS:

245 *Cast-iron and Malleable Iron Headers.* The pressure allowed on a water-tube boiler shall not exceed 160 lb. per sq. in. when the tubes are secured to cast-iron headers, nor 200 lb. when the tubes are secured to malleable iron headers. The form and size of the internal cross section perpendicular to the longer axis of a cast-iron or malleable iron header at any point shall be such that it will fall within a 7 in. by 7 in. rectangle.

PAR. 246. CHANGE NUMBER OF PAR. 246 TO PAR. 246*a* AND CHANGE THE WORD "WITH" IN SECOND LINE TO "TO."

PAR. 247. CHANGE NUMBER OF PAR. 247 TO PAR. 246*b* AND REVISE IT TO READ AS FOLLOWS:

b A cast-iron header when tested to destruction, shall withstand a hydrostatic pressure of at least 1200 lb. per sq. in. and a malleable-iron header, 1500 lb. A hydrostatic test at 400 lb. per sq. in. for cast iron and 500 lb. per sq. in. for malleable iron shall be made on all new headers with tubes attached.

PAR. 247. INSERT A NEW PAR. 247 TO READ AS FOLLOWS:

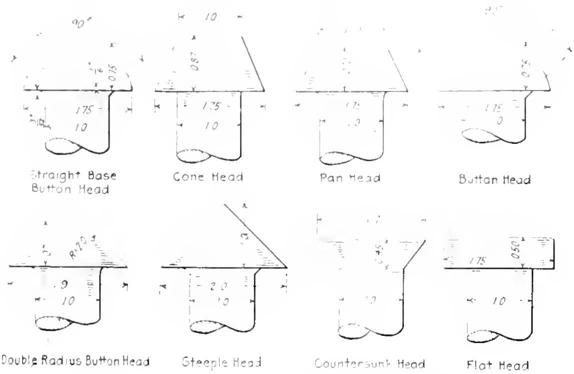
247 Where it is impossible to calculate with a reasonable degree of accuracy the strength of a boiler structure or any part thereof, a full sized sample shall be built by the manufacturer and tested to destruction in the presence of the Boiler Code Committee or one or more representatives of the Boiler Code Committee appointed to witness such test.

PAR. 250. CHANGE PAR. 250 TO READ AS FOLLOWS:

250 A fire-tube boiler shall have the ends of the tubes substantially rolled and beaded, or rolled and welded, at the firebox or combustion chamber end.

PAR. 251. CHANGE PAR. 251 TO READ AS FOLLOWS:

251 The ends of all tubes, suspension tubes and nipples shall be flared not less than $\frac{1}{8}$ in. over the diameter



Proportions may be larger or 1/10 smaller than those shown.
Fillets under heads may be used but are not required.

FIG. 17A ACCEPTABLE FORMS OF RIVET HEADS

of the tube hole on all water-tube boilers and superheaters, or they may be flared not less than $\frac{1}{8}$ in., rolled and beaded, or flared, rolled and welded.

PAGE 65

PAR. 253. CHANGE PAR. 253 TO READ AS FOLLOWS:

253 *Drilling of Holes.* All rivet holes and staybolt holes and holes in braces and lugs shall be drilled full size or they may be punched not to exceed $\frac{1}{4}$ in. less then full diameter for material over 5/16 in. in thickness, and $\frac{1}{8}$ in. less than full diameter for material not exceeding 5/16 in. in thickness, and then drilled or reamed to full diameter. Plates, butt straps, braces, heads and lugs shall be bolted in position for drilling or reaming all rivet holes in boiler plates except those used for the tack bolts required in assembling. Tack bolts for seams shall be not over 12 in. apart.

PAR. 254. CHANGE PAR. 254 TO READ AS FOLLOWS:

254 After drilling or reaming rivet holes the plates and butt straps shall be separated, the burrs and chips removed, the plates and butt straps reassembled metal to metal with barrel pins fitting the holes, and with tack bolts.

PAR. 255. ADD TO PAR. 255 THE FOLLOWING:

Forms of rivet heads that will be acceptable are shown in Fig. 17*a*.

PAR. 256. CHANGE PAR. 256 TO READ AS FOLLOWS:

256 Rivets shall be machine driven wherever possible with sufficient pressure to fill the rivet holes, and shall be allowed to cool and shrink under pressure. Barrel pins fitting the holes and tack bolts shall be used. The tack bolts shall be not over 12 in. apart, and a rivet shall be driven each side of each tack bolt before removing the tack bolt.

PAR. 257. CHANGE PAR. 257 TO READ AS FOLLOWS:

257 *Calking.* The calking edges of plates, butt straps and heads shall be beveled. Every portion of the sheared surfaces of the calking edges of plates, butt straps and heads shall be planed, milled or chipped to a depth of not less than $\frac{1}{8}$ in. calking shall be done with a round-nosed tool.

PAR. 258. CHANGE SIDEHEAD IN PAR. 258 TO READ AS FOLLOWS:

Manholes and Handholes.

ADD TO PAR. 258 THE FOLLOWING:

A handhole opening in a boiler, the greatest dimension of which exceeds 6 in., shall be reinforced in accordance with the rules for manholes.

PARS. 260-261

The Executive Committee of the Boiler Code Committee will report later respecting openings that need not be reinforced and on methods of reinforcing openings that need not come under the same rules as for manholes.

PAGE 67

PAR. 261. CHANGE THE TWO LINES OF PAR. 261 AT THE TOP OF PAGE 67 TO READ AS FOLLOWS:

l = length of center line of opening in shell in direction parallel to axis of shell plus the sum of the diameters of the rivet holes that come in or adjacent to the center line of the opening, in.

PAR. 266. CHANGE PAR. 266 TO READ AS FOLLOWS:

266 A vertical fire-tube boiler, except boilers of steam fire-engines, or boilers 24 in. or less in diameter, shall have not less than seven handholes, located as follows: Three in the shell at or about the line of the crown sheet; one in the shell at or about the water-line or opposite the fusible plug when used; three in the shell at the lower part of the waterleg. A vertical fire-tube boiler, submerged tube type, shall have two or more handholes in the shell, in line with the upper tube sheet. All boilers 24 in. or less in diameter shall have at least one opening for inspection and one opening in addition to the blow-off for washing out the boiler, these openings to be fitted with brass plugs.

PAGE 68

PAR. 268. CHANGE PAR. 268 TO READ AS FOLLOWS:

268 *Threaded Openings.* A pipe connection 1 in. in diameter or over shall have not less than the number of threads given in Table 7.

TABLE

If the thickness of the material in the boiler is not sufficient to give such number of threads, the opening shall be reinforced by a pressed steel, cast steel, or bronze composition flange, or plate, so as to provide the required number of threads.

When the maximum allowable working pressure exceeds 100 lb. per sq. in., a flanged nozzle shall be used for all pipe openings over 3 in. pipe size.

PAR. 269. CHANGE PAR. 269 TO READ AS FOLLOWS:

269 *Safety Valve Requirements.* Each boiler shall have two or more safety valves, except a boiler for which one safety valve having a relieving area of $\frac{1}{2}$ sq. in. or less, is required by the rules.

PAGE 69

PAR. 272. CHANGE PAR. 272 TO READ AS FOLLOWS:

272 Safety valves may be of the direct spring loaded pop type with seat and bearing surface of the disc inclined at any angle between 45 deg. and 90 deg. to the center line of the spindle. The valve shall be rated at a pressure 3 per cent in excess of that at which the valve is set to blow.

The method of computing the relieving area of the safety valves shall be as given in Par. 421 of the Appendix.

Safety valves may be used which give any opening up to the full discharge capacity of the area of the opening at the base of the valve, provided the movement of the valve is gradual so as not to induce lifting of the water in the boiler.

All safety valves shall be so constructed that no detrimental shocks are produced through the operation of the valve. Weighted lever safety valves shall not be used.

Par. 273. Change Par. 273 to read as follows:

273 Each safety valve shall be plainly marked by the manufacturer. The markings may be stamped on the body, cast on the body, or stamped or cast on a plate or plates riveted to the body, and shall contain the following:

a The name or identifying trademark of the manufacturer
b The nominal diameter
c The steam pressure at which it is set to blow
d Blow down, or difference between the opening and closing pressures
e The weight of steam discharged in pounds per hour at a pressure 3 per cent higher than that for which the valve is set to blow
f A.S.M.E. Std.

Par. 274. Change Par. 274 to read as follows:

274 The minimum allowable relieving capacity of the safety valve or valves required on a boiler shall be determined on the basis of 6 lb. of steam per hour per sq. ft. of boiler heating surface for water tube boilers. For all other types of power boilers with pressures above 100 lb., the minimum allowable relieving capacity shall be determined on the basis of 5 lb. of steam per hour per sq. ft. of boiler heating surface, and on the basis of 3 lb. with pressures at or below 100 lb. per sq. in. The heating surface shall be computed for that side of the boiler surface exposed to the products of combustion, exclusive of the superheating surface. In computing the heating surface for this purpose only the tubes, fireboxes, shells, tube sheets and the projected area of headers need be considered. The minimum number of safety valves required shall be determined on the basis of the minimum allowable relieving capacity and the relieving capacity marked on the valves by the manufacturer.

PAGES 70-71-72

Table 8. Transfer Table 8 to the Appendix after Par. 427 and renumber as Table 16.

PAGE 73

Par. 275*a*. Change Par. 275*a* to read as follows:

275 Safety valve capacity may be checked in any one of the three following ways, and if found insufficient, additional capacity shall be provided:

a By making an accumulation test; that is, by shutting off all other steam discharge outlets from the boiler and forcing the fires to the maximum. The safety valve equipment shall be sufficient to prevent an excess pressure beyond that specified in Par. 270.

PAGE 74

Par. 279. Add to the end of Par. 279 the following:

Where discharge pipes are used, the cross-sectional area at any point shall be at least equal to the combined areas of the discharge outlets of the valves discharging therethrough. Ample drainage shall be provided at or near each safety valve and where the water of condensation may collect.

Par. 282. Change Par. 282 to read as follows:

282 To insure the valve being free, each safety valve shall have a substantial lifting device by which the valve may be raised from its seat at least 1-16 in. when there is no pressure on the boiler.

Par. 283. Add to Par. 283 the following:

The seats and discs of safety valves shall be of non-ferrous material. The seat of a safety valve shall be fastened to the body of the valve in such a way that there is no possibility of the seat lifting.

Par. 284. Change Par. 284 to read as follows:

284 Springs used in safety valves shall not show a permanent set exceeding 1-16 in. ten minutes after being released from a cold compression test closing the spring solid. The spring shall be so constructed that the valve can lift from its seat at least 1-10 the diameter of the seat before the coils are closed or before there is other interference.

Par. 286. Change Par. 286 to read as follows:

286 The dimensions of flanges subjected to boiler pressue shall conform to the American Standard given in Tables 15 and 16 of the Appendix for the pressures therein specified, except that the face of the safety valve flange and the nozzle to which it is attached may be flat and without the raised face for pressures up to and including 250 lb. per sq. in. For higher pressures, the raised face shall be used.

Par. 287. Change Par. 287 to read as follows:

287 When the valve body is marked with the letters A.S.M.E. Std. as required by Par. 273, this shall be a guarantee by the manufacturer that the valve conforms to the details of construction herein specified.

Par. 288. Change Par. 288 to read as follows:

288 Every superheater shall have one or more safety valves near the outlet. The discharge capacity of the safety valve or valves on an attached superheater may be included in determining the number and size of the safety valves for the boiler, provided there are no intervening valves between the superheater safety valve and the boiler, and provided the discharge capacity of the safety valve or valves on the boiler, as distinct from the superheater, is at least 75 per cent. of the total valve capacity required.

PAGE 75

Par. 290. Change Par. 290 to read as follows:

290 Every boiler shall have proper outlet connections for the required safety valve or valves, independent of any other outside steam connection, the area of opening to be at least equal to the aggregate nominal area of all of the safety valves to be attached thereto.

An internal collecting pipe, splash plate or pan may be used, provided the total area for inlet of steam thereto is not less than one and one-half times the aggregate area of the attached safety valves. The holes in collecting pipes shall be at least 1/4-in. in diameter and the least dimension in any other form of opening for inlet of steam shall be 1/4-in.

Par. 291. Change Par. 291 to read as follows:

291 *Water Gage Glasses and Gage Cocks.* Each boiler shall have at least one water gage glass, the lowest visible part of which shall be not less than 2 in. above the lowest permissible water level. The lowest permissible water level for various classes of boilers shall be the location for the fusible plug as given in Par. 430 of the Appendix.

Par. 292. Change Par. 292 to read as follows:

292 No water glass connection shall be fitted with an automatic shut-off valve, except when the automatic shut-off valves are so constructed that the two connections to the water glass can be blown through separately and the steam connection cannot be entirely closed thereby. Where automatic water gages are applied they shall conform to the following requirements:

1. Check valves in upper and lower fittings must be of the non-ferrous ball type to avoid corrosion and the necessity for guides.

2. Ball check valves in upper and lower fittings must open by gravity, and the lower ball check valve must rise vertically to its seat.

3. The ball checks must not be smaller than 1/2-in. diameter, and the diameter of the circle of contact with

the seat must not be greater than $^2/_3$ of the diameter of the ball check valve. The annulus around the ball must not be less than $^1/_8$-in., and the travel movement from the normal resting place to the seat must not be less than $^1/_4$ in. The balls must be accessible for inspection.

4. The chambers in upper and lower fittings through which the balls pass on the way to their respective seats must be either square or hexagonal in shape.

5. The ball seat in the upper fitting must be a flat seat with either a square or hexagonal opening so that the stream passage can never be completely closed by this valve.

6. The shut-off valve in the upper fitting must have a projection which holds the ball at least $^1/_4$-in. away from its seat when the shut-off valve is closed.

7. The lower fitting must be provided with a positive means of rotating the ball. Means must also be provided for removal and inspection of lower ball check valve, while the boiler is under steam pressure.

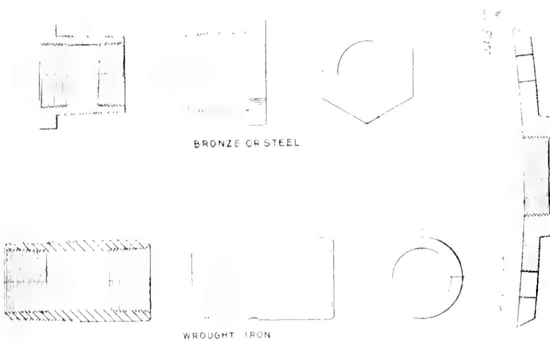


Fig. 18a Types of Boiler Flanges and Bushings

Par. 296. Add to the end of Par. 296 the following:

Where the use of a long pipe becomes necessary, a shut off valve or cock arranged so that it can be locked or sealed open may be used near the boiler. Such a pipe shall be of ample size and arranged so that it may be cleared by blowing out. Each boiler shall be provided with a $^1/_4$ in. pipe size valved connection for exclusive purpose of attaching a test gage.

PAGE 76

Par. 299. Change Par. 299 to read as follows:

299 *Nozzles and Fittings.* Flanged cast iron pipe fittings used for boiler parts, for pressures up to and including 160 lb. per sq. in., shall conform to the American Standard given in Tables 15 and 16 of the Appendix, except that the face of the flange of a safety valve as well as that of a safety valve nozzle, may be flat and without the raised face. For pressures above 160 lb. per sq. in., cast iron shall not be used for boiler pressure parts with exceptions specified in Pars. 9, 12 and 215. An allowable variation of 20 per cent from the flange thickness required by Tables 15 and 16 may be made for steel cast and forged steel fittings, leaving the drilling of bolt holes unchanged. For pressures above 250 lb. per sq. in., the flange thickness and the thickness of the bodies shall be increased to keep within the same deflection limits and to give at least the same factor of safety as the fittings specified in Tables 15 and 16. The flange of a safety valve may have a flat face for pressures up to and including 250 lb. per sq. in., and shall have a raised face at higher pressures; a safety valve nozzle may have a flat face for pressures up to and including 250 lb. per sq. in. and shall have a raised face at higher pressures. Tables 15 and 16 do not apply to flanges on the boiler side of steam nozzles or to flanges left by the manufacturer as part of the boiler, and do not apply to fittings designed as part of the boiler.

Par. 307. Change Par. 307 to read as follows:

307 *Blow-off Piping.* A surface blow-off shall not exceed $1^1/_2$ in. pipe size and the internal and external pipes, when used, shall form a continuous passage, but with clearance between their ends and arranged so that the removal of either will not disturb the other. A properly designed brass or steel bushing as shown in Fig. 18a or flanged connection, shall be used.

PAGE 77

Par. 311. Change Par. 311 to read as follows:

311 *a* On all boilers except those used for traction and portable purposes, when the maximum allowable working pressure exceeds 125 lb. per sq. in., each bottom blow-off pipe shall have two valves, or a valve and a cock, and such valves, or valve and cock, shall be extra heavy, except that on a boiler having multiple blow-off pipes, a single master valve may be placed on the common blow-off pipe from the boiler, in which case only one valve on each individual blow-off is required.

b All traction and portable boilers shall have a bottom blow-off valve; when the maximum allowable working pressure exceeds 125 lb. per sq. in., the blow-off valve shall be extra heavy.

Par. 314 Omit the last sentence so that Par. 314 reads as follows:

314 *Feed Piping.* The feed pipe of a boiler shall have an open end or ends inside of the boiler.

Par. 315. Change the last sentence of Par. 315 to read as follows:

The feed pipe shall be carried through the head or shell near the front end in the manner specified for a surface blow-off in Par. 307, and be securely fastened inside the shell above the tubes.

Add to Par. 315 the following:

In Fig. 18a is illustrated a standard form of flange for use on boiler shells for passing through piping such as feed, surface, blow-off connections, etc., and which permits of the pipes being screwed in solid from both sides in addition to the reinforcing of the opening in the shells.

In other types of boilers where both internal and external pipes making a continuous passage are employed, the boiler bushing or its equivalent shall be used.

Par. 317 Add to Par. 317 the following:

Wherever globe valves are used on feed piping, the inlet shall be under the disc of the valve.

PAGE 79

Par. 325. Change Par. 325 to read as follows:

325 Lugs or brackets, when used to support a boiler of any type, shall be properly fitted to the surfaces to which they are attached. The shearing and crushing stresses on the rivets used for attaching the lugs or brackets shall not exceed 8 per cent of the strength given in Pars. 15 and 16. For traction or portable boilers, studs with pipe threads may be used.

Par. 328. Change Par. 328 to read as follows:

328 A water-tube boiler shall have the firing doors, furnace inspection doors and clinker doors of the inward opening type, unless such doors are provided with substantial and effective latching or fastening devices to prevent them from being blown open by pressure on the furnace side.

PAR. 332. CHANGE PAR. 332 TO READ AS FOLLOWS:

332 After obtaining the stamp to be used when boilers are to be constructed to conform with the A.S.M.E. Boiler Code, it is understood that a state inspector, municipal inspector, or an inspector employed regularly by an insurance company which is authorized to do a boiler insurance business in the state in which the boiler is built and in the state in which it is to be used, is to be notified that an inspection is to be made and shall inspect such boilers during construction and after completion. At least two inspections shall be made, one before reaming rivet holes and one at the hydrostatic test. In stamping the boiler after completion, if built in compliance with the Code, the builder shall stamp the boiler in the presence of the inspector, after the hydrostatic test, with the A.S.M.E. Code stamp, the builder's name and the serial number of the manufacturer. A data sheet shall be filled out and signed by the manufacturer and the inspector. This data sheet together with the stamp on the boiler shall denote that it was constructed in accordance with the A.S.M.E. Boiler Code.

The name of the state in which the boiler is built shall be stamped under and about one-half inch below the symbol. The name or initials of the manufacturer shall be stamped below the name of the state, together with the serial number of the boiler, and not over one-half inch therefrom. (Samples of data sheets appear in the APPENDIX, after page 120.)

Stamps for the official symbol shown in Fig. 19 are obtainable from THE AMERICAN SOCIETY OF MECHANICAL ENGINEERS.

PAGE 80

REVISE FIG. 20 TO READ AS FOLLOWS:

PAGE 81

HEADING. MAKE HEADING OF P. 81 READ AS FOLLOWS:

A.S.M.E. Boiler Code

PART I—SECTION II

BOILERS USED EXCLUSIVELY FOR LOW PRESSURE STEAM AND HOT WATER HEATING AND BOILERS FOR HOT WATER SUPPLY[1]

PAR. 335. CHANGE CENTER HEAD ABOVE.

PAR. 335 FROM "BOILER MATERIALS" TO "GENERAL."

PAR. 336. INSERT ABOVE PAR. 336 THE FOLLOWING CENTER HEAD: "MATERIALS."

PAR. 339. CHANGE PAR. 339 TO READ AS FOLLOWS:

339 A boiler to be used exclusively for low pressure steam heating may be constructed either of cast iron, steel cast, or wrought iron or steel, or any combination of these, but in all cases the connecting rods and bolts shall be wrought iron or steel.

PAGE 82

PAR. 343. REVISE THE WORDING OF PAR. 343 AS FOLLOWS, AND ARRANGE IT AS A SINGLE PARAGRAPH:

343 In a *hot-water* boiler to be used exclusively for heating buildings or hot-water supply, when the diameter does not exceed 60 in. and the grate area does not exceed 10 sq. ft., or equivalent as defined in Pars. 359 and 360, longitudinal lap joints will be allowed. When the grate area exceeds 10 sq. ft., or equivalent as defined in Pars. 359 and 360, and the diameter of the boiler does not exceed 60 in., longitudinal lap joints will be allowed provided the maximum allowable working pressure does not exceed 50 lb. per sq. in.

[1] Domestic kitchen range boilers and their water backs, furnace heating coils and their appurtenances and domestic coil or pipe, gas or oil heaters, are not included under this Section.

PAR. 345. CHANGE PAR. 345 TO READ AS FOLLOWS:

345 A boiler used for low pressure steam heating or for hot water supply shall be provided with washout holes for the removal of any sediment that may accumulate therein. Steel shell boilers of the locomotive or vertical fire-tube type shall conform to the requirements of Pars. 265 and 266 for washout holes.

PAR. 347. IN FOURTH LINE OMIT THE FOLLOWING WORDS:

"Or any internal pipe in the boiler."

PAR. 354. CHANGE PAR. 354 TO READ AS FOLLOWS:

354*a*. No shut-off of any description shall be placed between the safety or water relief valves and boilers, nor on discharge pipes between them and the atmosphere.

b. No boiler for hot water supply shall be connected to a water supply pipe fitted with a check valve or pressure reducing valve.

PAGE 84

TABLE 9. TITLE OF TABLE 9 TO BE CHANGED TO READ AS FOLLOWS:

Allowable Sizes of Safety Valves for Steam Heating Boilers, of Water Relief Valves for Water Heating Boilers, and of Hot Water Supply Boilers.

PAR. 356. CHANGE PAR. 356 TO READ AS FOLLOWS:

356 Each safety valve used on a *steam* heating boiler shall have a substantial lifting device by which the valve may be raised from its seat at least 1/16 in. when there is no pressure on the boiler.

PAGE 85

PAR. 359. INSERT THE FOLLOWING CENTER HEAD ABOVE PAR. 359:

GRATE AREA

PAR. 359. CHANGE PAR. 359 TO READ AS FOLLOWS:

359 *Double Grate Down Draft Boilers.* In boilers of this type the grate area shall be taken as one and one-quarter times the area of the larger grate.

PAR. 361. CHANGE PAR. 361 TO READ AS FOLLOWS:

361 *Steam Gages.* Each *steam* boiler shall have a steam gage connected to the steam space or to the water column, or its steam connection, by means of a syphon or equivalent device of sufficient capacity to keep the gage tube filled with water and so arranged that the gage cannot be shut off from the boiler except by a cock placed near the gage and provided with a tee or lever handle, arranged to be parallel with the pipe in which it is located when the cock is open. Connections to gages shall be of brass, copper or bronze composition. The dial of a steam gage for a *steam* heating boiler shall be graduated to not less than 30 lb.

PAGE 86

PAR. 363. ADD TO PAR. 363 THE FOLLOWING:

Temperature Regulator. A temperature regulator shall be applied to *hot water* supply boilers which will prevent the water temperature from rising above 200 deg. fahr.

PAR. 365. CHANGE PAR. 365 TO READ AS FOLLOWS:

365 *Damper Regulators.* When a pressure damper regulator is used, it shall be connected to the steam space of the boiler.

PAGE 87

Par. 373. Change Par. 373 to read as follows:

373 *Hot-water* boilers for a maximum allowable working pressure not exceeding 30 lb. per sq. in., used exclusively for heating buildings or for hot-water supply, when constructed of cast iron, steel cast, or wrought iron or plate steel or any combination of these, shall be subjected to a shop test of 60 lb. per sq. in. hydrostatic pressure applied to the boiler or the section thereof.

Par. 374. Change Par. 374 to read as follows

374 A maximum allowable working pressure in excess of 30 lb. per sq. in. will be allowed on a hot-water boiler constructed of cast iron, steel cast, or wrought iron or plate steel or any combination of these, used exclusively for heating buildings or for hot-water supply, provided such boilers or their sections have been subjected to a shop hydrostatic test of two and one-half times the actual working pressure

Par. 377. Change Par. 377 to read as follows:

377 *Name.* All boilers referred to in this section shall be plainly and permanently marked with the manufacturer's name and the maximum allowable working pressure.

All heating boilers built according to these rules may be marked A.S.M.E. standard.

PAGE 89

Heading. Insert above heading of p. 89 the following:

A.S.M.E. Boiler Code

PAGE 90

Par. 384. Change Par. 384 to read as follows:

384 The shell or drum of a boiler in which a typical "lap seam crack" is discovered along a longitudinal riveted joint for either butt seam or lap joints shall be permanently discontinued for use under steam pressure. By "lap seam crack" is meant the typical crack frequently found in lap seams extending parallel to the longitudinal joint and located either between or adjacent to rivet holes.

PAGE 91

Par. 391*a*. Change Par. 391*a* to read as follows:

a By making an accumulation test, that is, by shutting off all other steam discharge outlets from the boiler and forcing the fires to the maximum. The safety valve equipment shall be sufficient to prevent an excess pressure beyond that specified in Par. 270.

Par. 392. Change Par. 392 to read as follows.

392 In case either of the methods outlined in sections *b* or *c* of Par. 391 is employed, the safety valve capacities shall be those given in Table 16.

PAGE 95—APPENDIX

Heading. Insert above heading of Page 95 the following:

A.S.M.E. Boiler Code

PAGE 93

Par. 402. Change Par. 402 to read as follows:

402 When the maximum allowable working pressure exceeds 125 lb. per sq. in., the blow-off pipe shall be extra heavy from boiler to valve or valves, and shall run full size without reducers or bushings. All fittings between the boiler and valve shall be steel or extra heavy fittings of bronze, brass, malleable iron or cast-iron. In case of replacement of pipe or fittings in the blow-off lines, as specified in this paragraph, they shall be installed in accordance with the rules for new installations. (See Pars. 307-313.)

Par. 403. Add to Par. 403 the following:

In case of replacement of pipe or fittings in the blow-off lines as specified in this paragraph, they shall be installed in accordance with the rules for new installations. (See Pars. 307-313.)

Par. 408. Change Par. 408 to Par. 408*a*.

Par. 409. Change Par. 409 to Par. 408*b* and insert a new Par. 409 as follows:

Where repairs are necessary which in any way affect the working pressure or safety of a boiler, a state inspector, municipal inspector, or an inspector employed regularly by an insurance company which is authorized to do a boiler insurance business in the state in which the boiler is used, shall be called for consultation and advice as to the best method of making such repairs; after such repairs are made they shall be subject to the approval of a state inspector, municipal inspector, or an inspector regularly employed by an insurance company which is authorized to do a boiler insurance business in the state in which the boiler is used.

PAGE 95

Heading. Insert above heading of p. 95 A.S.M.E. boiler code.

PAGE 103

Par. 417

Change first sentence of Par. 417 to read as follows:

417 Figs. 28 and 29 illustrate other joints that may be used in which eccentric stresses are avoided.

PAGE 107

Par. 421. Change Par. 421 to read as follows:

421 *Method of Computing Discharge Capacity.* The required discharge capacity of a safety valve or valves for a boiler may be based either on the heat units in the fuel consumed or on the amount of steam generated.

The number of heat units that each safety valve will handle, for valves of the ordinary types in which the discharge capacity is proportioned to the lift, may be obtained as follows:

$U = 161{,}000 \times P \times D \times L$ for Bevel Seats at 45 deg.
$U = 227{,}500 \times P \times D \times L$ for Flat Seats
$U = 72{,}500 \times P \times A$ for seats of any angle

The amount of steam that a valve will discharge may be found as follows:

$W = 110 \times P \times D \times L$ for Bevel Seats at 45 deg.
$W = 155 \times P \times D \times L$ for Flat Seats
$W = 50 \times P \times A$ for seats of any angle

where

U = Number of heat units per hour that a safety valve will handle, B.t.u.
W = Quantity of steam that a safety valve will handle per hour, lb.
P = Absolute boiler pressure = gage pressure + 14.7 lb. per sq. in.
D = Inside diameter of valve seat, in.
L = Vertical lift of valve disc, measured with 3 per cent excess pressure, in.
A = Relieving area in sq. in. = $3.1416 \times D \times L \times$ sine of seat angle.

Par. 422. Change Par. 422 to read as follows:

422 The maximum quantity of fuel C that can be burned per hour at the time of maximum forcing is determined by a test. The maximum number of heat units per hour, or $C \times H$ is then determined, using the values of H given in Par. 427. The weight of steam generated per hour is found by the formula:

$$W = \frac{C \times H \times 0.75}{1{,}100}$$

The sum of the safety valve capacities marked on the valves shall be equal to or greater than W.

PAGE 108

PAR. 423. REPLACE MATTER AFTER STATEMENT OF EXAMPLE BY THE FOLLOWING:

$$C \times H = 2150 \times 12{,}100 = 26{,}015{,}000$$
$$W = C \times H \times 0.75 \div 1100 = 17{,}740$$

A $3\frac{1}{2}$ in. bevel seated valve with 0.11 in. lift would discharge in heat units

$$U = 161{,}000 \times 239.7 \times 3\tfrac{1}{2} \times 0.11$$
$$= 14{,}858{,}000$$

and in weight of steam

$$W = 110 \times 239.7 \times 3\tfrac{1}{2} \times 0.11$$
$$= 10{,}150$$

From which it can be seen that either method indicates that two such valves will give the proper relieving capacity.

PAR. 424. REPLACE MATTER AFTER STATEMENT OF EXAMPLE BY THE FOLLOWING:

$$C \times H = 2000 \times 6400 = 12{,}800{,}000$$
$$W = C \times H \times 0.75 \div 1100 = 8730$$

A bevel seated $3\frac{1}{2}$ in. valve is marked by the manufacturer 0.11 in. lift and discharge capacity for 100 lb. pressure = 4840 lb.; hence two such valves would be required.

ALSO CHANGE HEADINGS IN TABLES FOLLOWING THIS SENTENCE TO READ AS FOLLOWS:

H = B.t.u. per lb.
and H = B.t.u. per cu. ft.

PAGE 111

TABLE 16

TABLE 16. THIS TABLE TO BE RENUMBERED. IN THE NOTES UNDER TABLE 16 ADD AFTER THE LAST SENTENCE THE FOLLOWING:

All extra heavy fittings and flanges to have a raised surface of 1/16 in. high inside of bolt holes for gaskets.

PAGE 113—APPENDIX

PAR. 428. ADD AT THE END OF PAR. 428:

and shall be renewed at least once each year.

PAR. 430. ADD THE FOLLOWING CLAUSE TO THE END OF PAR. 430:

r Fire Engine Boilers are not usually supplied with

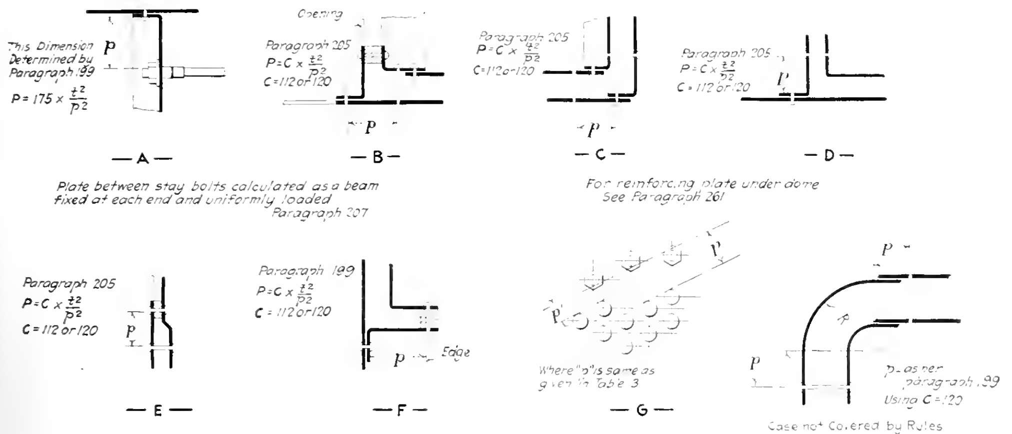

FIG. 31 DETAILS SHOWING APPLICATION OF PARS. 205, 206 AND 207 TO THE STAYING OF WET-BOTTOM BOILERS

PAR. 425. REPLACE MATTER AFTER STATEMENT OF EXAMPLE BY THE FOLLOWING:

$$C \times H = 1000 \times 18{,}500 = 18{,}500{,}000$$
$$W = C \times H \times 0.75 \div 1100 = 12{,}620$$

A bevel seated $2\frac{1}{2}$ in. valve is marked by the manufacturer 0.08 in. lift and discharge capacity for 275 lb. pressure = 6350 lb., hence two such valves would be required.

PAR. 426. REPLACE MATTER AFTER STATEMENT OF EXAMPLE BY THE FOLLOWING:

$$C \times H = 3000 \times 960 = 2{,}880{,}000$$
$$W = C \times H \times 0.75 \div 1100 = 1960$$

A bevel seated 2 in. valve is marked by the manufacturer 0.07 in. lift and discharge capacity for 150 lb. pressure = 2500 lb., hence one such valve would be required.

PAGE 109

PAR. 427. CHANGE FIRST SENTENCE OF PAR. 427 TO READ AS FOLLOWS:

427 For the purpose of checking the safety valve capacity as described in Par. 422, the following values of heats of combustion of various fuels may be used.

fusible plugs. Unless special provision is made to keep the water above the firebox crown sheet other than by the natural water level, the lowest permissible water level shall be at least 3 in. above the top of the firebox crown sheet.

Under Table 3 reference is made to Fig. 31 showing application of Pars. 205, 206 and 207.

RECOMMENDATIONS FOR REPAIRS WHEN MADE BY WELDING AND REINFORCING BY THE ELECTRIC, OXY-ACETYLENE, OR OTHER PROCESSES

From General Rules and Regulations Prescribed by the Board of Supervising Inspectors, U. S. Steamboat-Inspection Service

"All calking edges on internally fired boilers may be reinforced by these processes.

"Calking edges of the shells of externally fired boilers, above the fire line only, may be reinforced.

"Cracks extending from edge of lap to rivet, except on seams below the fire line in externally fired boilers, may be welded.

"Cracks not exceeding 30 inches in length in back connec-

tion sheets, wrapper sheets, bottoms of combustion chambers, heads, and other stayed surfaces may be repaired by welding.

"Where cracks are repaired by welding, holes shall be drilled entirely through the plate at each extreme end of the crack, except in small cracks from rivet to calking edge.

"Circumferential or lengthwise cracks not exceeding 16 inches in length in plain or corrugated furnaces may be welded.

"Where plates in back sheets of back connections, wrapper sheets of sides and bottoms of back connections of any boilers, side sheets and legs of furnaces and bottoms of furnaces of fire-box boilers, and other stayed surfaces are reduced in thickness not exceeding 40 per cent of the original thickness, they may be reinforced, such reinforcing not to exceed an area of 200 square inches in any one plate.

"When such reinforcing extends over stays and braces, such stays and braces shall come completely through the reinforcing so as to be plainly visible to the inspectors.

"When the corroded portion of stayed or riveted surfaces of the back sheets or wrapper sheets or bottoms of back connections of any boilers, or side sheets and bottom sheets of furnaces or legs of fire-box boilers exceeds 300 square inches, the same may be repaired by the removal of the corroded portion and the replacement thereof by a new piece of plate, the edges of the new plate being welded in position.

"Staybolts, braces, or rivets shall pass through the body of the new plate as before, the area of the new piece not to exceed 24 inches by 24 inches, or 30 inches, in any one direction, the welded edges to be V'd or beveled along the joint prior to welding.

"Where plates of shells and other parts of internally fired boilers subject to tensile strain are reduced in thickness by corrosion not to exceed 25 per cent of the original thickness, they may be reinforced, such reinforcing not to exceed an area of 200 square inches.

"Where calking edges and laps have been reinforced, local inspectors shall require the rivets to be cut out and redriven if they find by inspection that it is necessary.

"No welding shall be allowed in cracks in the shell plates or other plates subject to tensile strain.

"Cracks extending through rivet holes in single-riveted or double-riveted seams in stayed surfaces of back connections of any boilers or side sheets of legs or bottoms of fire-box boilers which are stayed surfaces may be welded up to a length of 6 feet exclusive of rivet holes.

"Where cracks extend through rivet holes in stayed surfaces, the piece extending from the rivet to the edge of the lap may be removed where convenient to do so, and the place where the piece has been removed may be replaced by being built up and reinforced by either of these processes.

"Where leaks develop around staybolts and the staybolts are otherwise intact, the nuts may be removed from the ends of the staybolts, and the staybolts may be welded into the shell by welding a beveled collar or ring aroung the staybolt. The width and depth of such collar shall equal one-half of the diameter of the staybolt. In all such cases of applying welding rings or collars around staybolts, the material shall be hammered while in a glowing state as it is applied.

"In all cases where metal is deposited on stayed surfaces, the operator shall hammer, when practicable, the deposited metal while it is in a glowing state.

. . . .

"Cracks in wrought-iron or wrought-steel headers, and cracks or sand holes in cast-steel, semisteel, ferrosteel, malleable-iron or cast-iron headers, manifolds, crosses, tees, and ells may be repaired by welding cracks or flowing metal into sand holes. Such repaired material other than headers and manifolds shall be subjected to a hydrostatic test of three and one-half times the working pressure after such repairs are made. Reinforcing by building up of any of the above-mentioned articles other than headers shall not be allowed.

"When crown-bar bolts have deteriorated or wasted away at top of combustion chamber under the crown bars, such deterioration not to exceed 25 per cent of the original diameter of the bolt, such bolts may be built up or reinforced by any process of autogenous welding.

"Where tube sheets of boilers have deteriorated not to exceed 25 per cent of their original thickness, or where cracks have developed in tube sheets, the same may be reinforced and repaired by any process of autogenous welding, and the beading on the end of tubes may be welded to the tube sheets by the same process."

CORRESPONDENCE

Contributions to the Correspondence Departments of The Journal by members of The American Society of Mechanical Engineers are solicited by the Publication Committee. Contributions particularly welcomed are suggestions on Society Affairs, discussions of papers published in The Journal, or brief articles of current interest to mechanical engineers.

The Logic of Inspection

To the Editor:

Referring to the paper on The Logic of Inspection, presented by Mr. A. L. De Leeuw at the Annual Meeting, I would say there are very few, if there are any, engineers who do not believe that inspection is the logical and final operation on any manufactured product. The question is, What relation should inspection have to the various machining operations; what form and type of gages should be used; and what manufacturing tolerances are to be permitted?

We will take a concrete example. Suppose it is necessary to manufacture a 3-in. American high-explosive shell. The conditions regarding the manufacture of this product are very clearly set forth in the Government specifications, and tolerances have also been established by the Ordnance Department. A complete outline of the proper methods of manufacture has also been given. The question for the manufacturer to decide is how he can best adapt his own equipment to the production of this particular product, what gages are necessary, and what are the most particular requirements which must be met.

It might be stated that the requirements for a high-explosive shell comprise several points, the more important ones being that the bore must be concentric with the external circumference within very definite limits, the shell prior to loading must be of a certain weight within definite limits, and the shape must conform to Government specifications.

Now, regarding the shape of a high-explosive shell, it might be stated that in order for it to follow the predetermined parabolic curve, the center of gravity of the shell must be in the right place. It is therefore evident that the shape of the shell must be such as to keep it in proper balance when in flight. The only parts of the shell that bear in the bore of the gun are that portion near the base of the ogive, and the rotating band. All other portions of the shell are free and do not contact with the bore. Hence, here are two points which must receive careful attention.

Regarding concentricity, as far as I know, no tolerances are given for this in the original U. S. specifications. The only complete specifications regarding tolerances and location of the center of gravity are the French, and they hold this one point to be more particular than any other. A shell which is not concentric, or, in other words, is out of balance, will not shoot accurately, and a shell in which the center of gravity is so placed

that it does not follow a predetermined curve will not shoot accurately. These questions which have to do with design are beyond the scope of the mechanical engineer and are up to the ballistic expert. The manufacturer, however, must meet the specifications as set down by these ballistic experts.

As an instance to show the importance of weight, it might be stated that when certain Canadian plants started to manufacture shells for the British Government they experienced great difficulty at first in producing shells which would pass the inspectors, owing to a misunderstanding regarding the requirements that had to be met. The shells were made within the desired tolerances for size as called for by the government specifications, but the weight of these shells was overlooked, and hence a large majority were rejected by the inspectors because of being short on the point of weight. It was found that when a shell was made to the minimum limits for diameter and length, it was below the minimum weight, and hence could not be accepted. Experience soon demonstrated to the Canadian manufacturers that the weight of the shell was just as important as any of the other requirements, and as a natural outcome of the difficulty, the shells were made to the tolerances called for by the government specifications, leaving the rear end of the shell longer than necessary. After the shell was completely machined, the base end was faced off until the desired weight was obtained. Points such as this proved to be of valuable assistance to the Canadian manufacturers in enabling them to meet their contracts.

While it is not my endeavor to discuss the subject fully, it is advisable, however, to state that gaging of the shell is no doubt the one operation that requires the most careful attention. Gages have been designed for shells that were not directly adapted to the work required of them, with the result that much work has been spoiled. One of the fundamental points regarding gaging is that the work should be located in the gage from the same point that it is located from when being machined, otherwise tolerances on the product cannot be set with any degree of certainty, and it is impossible to obtain interchangeable manufacture.

A point in connection with the paper presented by Mr. De Leeuw which was out of place, was his reference to the specification dealing with leather belting. This specification had nothing whatsoever to do with the inspection of leather belting, but what it did set forth was the process by which leather belting could be made in order to meet Government specifications, and as such would be of valuable assistance to any manufacturer engaged in this work who had not previously engaged in this particular line of manufacture.

The American Society of Mechanical Engineers can surely be of great assistance to our Government, but in order to do so it is necessary to get down to concrete cases rather than be satisfied with generalities. It is to be hoped that future papers presented before the Machine Shop Section of the A. S. M. E. will contain concrete and definite information on this interesting and important subject.

DOUGLAS T. HAMILTON.

Brooklyn, N. Y.

TO THE EDITOR:

In the first paragraph of his letter Mr. Douglas T. Hamilton says: "The question is, What relation should inspection have to the various machining operations; what form and type of gages should be used, and what manufacturing tolerances are to be permitted?" I fully realize that it was entirely out of the scope of the desired discussion to answer such questions as given above except in a very general way, and I attempted to bring out the necessity of careful consideration of such and other questions. I did not confine myself to the inspection of shells or ammunition because there is no essential difference between the rules which should govern the inspection of such materials and those for any other manufactured product.

That it is possible to give tolerances on the dimensions of a shell which conflict with the tolerances in regard to the weight of a shell shows conclusively that logic is required not merely to determine that there should be inspection, but also that specifications, limits, tolerances, etc., should be given in a logical manner.

Elsewhere Mr. Hamilton says: "Another point in connection with Mr. De Leeuw's paper, which appeared out of place, was his reference to the specification dealing with leather belting. This specification had nothing whatsoever to do with the inspection of leather belting, but what it did set forth was the process by which leather belting could be made in order to meet Government specifications, and as such would be of valuable assistance to any manufacturer engaged in this work who had not previously engaged in this particular line of manufacture." This last quotation shows quite clearly that Mr. Hamilton did not get the drift of what I said. The instance quoted in regard to specifications of leather belting were most decidedly taken from the specifications of users of leather belting; which means that belting not coming up to these specifications would be rejected by the user. I have copies of these specifications in my possession, and I would say that they were not written by the Government, but by some of the largest private concerns in this country. They were by no means information given by the user to some future belt maker, but instructions to an existing belt maker as to what he would have to furnish. The specifications were of such a nature that there was only one thing to do, and that was to take the word of the maker that he had followed the instructions, for the finished product would not show in any way that the specifications had been met. How Mr. Hamilton got the idea that these were Government specifications, and that they were made for the purpose of giving assistance to some future manufacturer, is more than I can tell.

Whether the papers presented before the Machine Shop Session of the A.S.M.E. at the last meeting were the papers most needed at the present time I do not care to discuss, but I feel that if the meeting had followed the lines of Mr. Hamilton's discussion, and had tried to consider in detail every feature of every piece of ordnance or ammunition which this Government may require, this meeting, starting Thursday afternoon, December 5, 1917, would probably have adjourned some Thursday afternoon in 1970! As to my share in the meeting, I merely tried to emphasize the necessity of logical inspection in order to make inspection not only profitable, but even possible.

A. L. DE LEEUW.

Plainfield, N. J.

Topographic surveys and mapping in relation to present military activities were discussed at a recent "patriotic" meeting of the American Institute of Mining Engineers by David White of the U. S. Geological Survey. There are 38 parties of topographers in the field, and the survey is now covering—on a scale of 1 mile to the inch—between 100,000 and 200,000 square miles per month. The survey has now one hundred men wearing the uniform of the United States.

SOCIETY AFFAIRS

A Record of the Current Activities of the Society, Its Members, Council, Committees, Sections and Student Branches; and an Account of Professional Affairs of Interest to the Membership

PROGRESS in the world has been through vicarious sacrifice, and the supreme benefit of this war, besides the attainment of opportunity for the self-determination of peoples great and small, is that of purification through the suffering caused by the war. It is essential that the suffering be for the good of others in order that one may benefit by the suffering.

One of the finest women I know, who has two sons at the front, and who has always, so far as one could observe, lived a life of service for others, recently told me that she is hoping that on the return of her boys she will be worthy to receive them.

We are constantly hearing of the failure to recognize the engineer in this war—that it is an engineering war; and President Taft, in his address before the Society at the Annual Meeting, said: "Now you engineers, all, constitute one of the two professions that are indispensable to the country in the carrying on of the struggle to which the people of the United States are about to devote themselves, yours and the medical profession; you as the constructors of all the material and all the equipment of which so much is needed now in modern warfare to make effective the work of our boys at the front, and the medical profession to furnish, so far as may be, the aid in restoring to the ranks those whom the fortunes of war disable."

Credit and recognition will be in the proportion that we unselfishly devote ourselves and make the sacrifices. It becomes increasingly difficult to receive with patience letters from members doubting the benefit that they obtain from the Society. It does not occur to them that membership in the Society is an opportunity to render greater service through an organization than could be rendered individually.

The Society is increasing its activities rapidly. The Presi-

THE SPRING MEETING AT WORCESTER

The following announcement regarding the convention to be held in Worcester, Mass., June 4 to 7, made by the Committee on Meetings and the Worcester Local Committee, evidences the intention of the committees to make this another war convention. Every member within reasonable distance of Worcester should make it his business to be present.

TENTATIVE PROGRAM

TUESDAY, JUNE 4

Afternoon: (Hotel Bancroft)
Registering of Members and Guests at Society Headquarters

Evening: (Hotel Bancroft)
Address of Welcome, followed by Reception and Dance

WEDNESDAY, JUNE 5

NEW ENGLAND DAY

Morning: (Worcester Polytechnic Institute)
Business Meeting
First New England Session, with opening address by Mr. Charles Washburn on the Industries of Worcester. Buffet lunch served at the Institute. During the morning and afternoon sessions it is proposed also to discuss the Textile Industry in Relation to the War; the Shipbuilding Industry; and the Manufacture of Small Arms and Gun Carriages, with reference to these industries as developed in New England

Afternoon: (Hotel Bancroft)
Second New England Session
General Session with technical papers
Industrial Safety and Workmen's Compensation Session

Evening: (Hotel Bancroft)
General War Session. The general theme of this

Evening: (Hotel Bancroft) Continued
evening session will be How the Engineering Societies Can Assist in the Procurement Program of the Government. Some major topics to be discussed are: Ordnance and Ships for the Navy Department; Munitions for the Army; Aircraft Material; Merchant Ships; Training of Labor, etc.

THURSDAY, JUNE 6

Morning: (Worcester Polytechnic Institute)
General Session with technical papers
Fuel Session
Public Relations Session

Afternoon: (Norton Company's Plant)
Luncheon
Inspection of the Norton Company's community housing and garden projects

Evening: (Worcester Country Club)
Dinner
Illustrated Lecture

FRIDAY, JUNE 7

Morning: Automobile Trip to Camp Devens, via Clinton Dam
Lunch at Camp Devens

Afternoon: Auto Trip to Concord, Lexington and return via the Wayside Inn
Afternoon tea at the Wayside Inn

[illegible] were [illegible] in Washington, to approve, [illegible] the applications by one of the Departments, of suggestions made by the Society at its Annual Meeting.

One of the problems of the war is that of developing the necessary skilled labor, and it was suggested by one of the boards in Washington that this could be accomplished by converting the schools of higher technical education into trade schools, and for a period of five months, commencing May 1, to absolutely stop all higher technical education. Our Council strenuously protested. We are pleased to report that the imminence of such a drastic action as shutting down the schools of higher technical education has, for the present, disappeared; and that the consideration of the whole subject is now in the hands of the Committee on Education and Special Training, the membership of which is made up from leading officers of the Army in its several bureaus, civilian representatives of the U. S. Bureau of Education, the engineering colleges, trade schools, corporation schools, and the Vocational Board; and a committee of this Society has been appointed, of which Prof. R. H. Fernald is chairman, consisting of Mr. F. A. Geier, Prof. Arthur L. Williston, Dean Herman Schneider, and Dr. C. R. Mann. It is the intention of this committee to assist the Government in the development of the nation's resources for the training of men without curtailing the steady flow of professional men. Recent addresses by the Secretaries of the Navy and of War have emphasized the necessity of maintaining at the highest rate the production of technically trained men, and they have appealed to the parents of the boys of the nation to send their sons to technical colleges.

Our Committee on Engineering Resources, of which Mr. George J. Foran is chairman, has lost, through the demands for personal service at Washington, Major J. H. Barr and Mr. A. D. Blake, and these vacancies have been filled by the appointment of Mr. Herman Greul and Mr. F. H. Colvin. The other members of the committee are Mr. Henry C. Meyer, Jr., and Prof. C. M. Allen, of Worcester. A most remarkable achievement has been made, and a special report on this will appear next month. This service is not only for the purpose of furnishing specialists for all demands of the Government, but to furnish specialists to the industries both during the period of the war and afterward.

The Committee on Gages, also a result of a suggestion of our Semi-Annual Meeting, has secured a substantial beginning of the movement to have departments of the Government have their gages certified in one place, namely, the Bureau of Standards, in distinction from having independent sources of authority with obvious possible differences, causing lack of interchangeability of completed parts.

The Committee on Fuel Conservation, of which Professor Breckenridge is chairman, has been very active, and, through Mr. David Moffat Myers, of the committee, who has, by virtue of the committee's activity, been invited by Dr. Garfield to be on his personal staff as technical adviser, is getting out a series of brochures on fuel conservation. Mr. F. R. Low, Editor of *Power*, and speaking for the McGraw-Hill Company, has tendered the patriotic services of members of the editorial staffs of the several publications of that company.

We have also furnished the Fuel Administrator, through Mr. Myers, with the names of our prominent members familiar with fuel economy in each of the states of the Union, and it is the Fuel Administrator's expectation to inform the state fuel administrators of the names of these experts, with the suggestion that the state fuel administrators avail themselves of technical advice.

It is evident from the way matters are managed throughout the United States, that the engineer is not yet the obvious man to do engineering work. By virtue of the fact that members of the other professions, particularly of the legal profession, have apparently made greater efforts to render public service, they are more frequently called to public office. Therefore, when and even before the invitation comes to any engineer to render service, it should be expected that it will be at personal sacrifice. Such sacrifice should be made as a means of advancing our country's cause, and the standing of one's profession.

There is one activity which the Society might well undertake: namely, that of conserving those industries which have been dislocated, and, in some cases, actually put out of business by the war—as a type, the jewelry industry. There is a vast industry, with numerous skilled workers, especially fitted for certain classes of work. There seems to be no agency yet developed in the Government for foreseeing such disaster and arranging in advance that the organizations of these so-called non-essential industries shall be held together by the placing in these industries of Government work and which can be performed with comparatively slight readjustment.

At the Spring Meeting in Cincinnati the convention voted that it was the duty of all patriotic citizens to exchange data so that there would be the freest opportunity for all manufacturers to undertake work. The committee appointed at that time has suffered through the loss of some of its members in active service in the war, and at the last Council meeting a new committee was appointed, and it is hoped that they will be able to take up in addition to the technical features of such a work the broader conservation of industries as a stabilizing element of the nation so essential while at war.

The Secretary could enumerate numerous undertakings which the Society could take up with advantage, and solicits the membership to offer their services to serve on committees and make the sacrifices of time and money to carry out this service for the profession and for their country.

CALVIN W. RICE,
Secretary.

Nominations for Officers of the Am.Soc.M.E.

FOR ELECTION IN DECEMBER 1918

The Constitution of the Society in C 47 provides among the Annual Committees:

> "A Nominating Committee appointed by the President."

It further provides in C 48:

A "Special Nominating Committee: Twenty or more persons entitled to vote may constitute themselves a Special Nominating Committee, with the same powers as the Annual Nominating Committee."

The procedure in the nominations for office is provided in the following By-Laws:

B 27 A Nominating Committee of five members, not members of the Council, shall be appointed before February first of each year by the President. The Secretary shall publish the names of this Committee in the March issue of THE JOURNAL together with a request to the voting membership of the Society that they recommend to the Committee the names of eligible persons for the elective offices to be filled at the next election. This Committee shall deliver to the Secretary in writing between the first and the fifteenth of June the names of its nominees for the various elective offices next falling vacant under the Constitution, together with the written con-

sent of each nominee. The names of the nominees for the various offices proposed by this Committee shall be published by the Secretary under the names of the Committee in the July issue of THE JOURNAL.

B 28 A special Nominating Committee, if organized, shall on or before October fifteenth, present to the Secretary the names of its nominees for the elective offices next falling vacant under the Constitution, together with the written consent of each nominee. The names of the nominees for the various offices proposed by this Committee shall be published by the Secretary under the names of this Committee in the November issue of THE JOURNAL.

There are to be elected in December next

A President to hold office for one year

Three Vice-Presidents to hold office for two years

Three Managers to hold office for three years

A Treasurer to hold office for one year

The President, Charles T. Main, has appointed the following Nominating Committee for these officers:

George R. Wadleigh, of St. Louis, Mo.

William P. Caine, of Ensley, Ala.

C. F. Hirshfeld, of Detroit, Mich.

L. P. Breckenridge, of New Haven, Conn.

Thomas E. Durban, of Erie, Pa.

These names were selected by the following Sections, grouped geographically, and accepted by the President:

GROUP 1 Minnesota, Los Angeles, St. Louis and San Francisco

GROUP 2 Atlanta, Baltimore, Birmingham, Cincinnati and New Orleans

GROUP 3 Chicago, Detroit, Indianapolis and Milwaukee

GROUP 4 Boston, Connecticut, New York and Worcester

GROUP 5 Buffalo, Erie, Philadelphia and Ontario

This Nominating Committee is to meet at the Spring Meeting of the Society in Worcester, Mass., June 4 to 7, and would be pleased to receive suggestions from the membership.

Under the terms of By-Laws B 27 and B 28 the voting membership are requested to send the Nominating Committee or Committees, in care of the Secretary, 29 West 39th Street, New York, N. Y., their recommendations of names for any or all of the elective offices to be filled at the next election.

These recommendations should be sent in early and not later than June 1.

Engineers in Government Service

THE engineering societies have during the past few months supplied to various Government departments, in response to their individual requests, several thousands of names of engineers from which men have been selected to fill a great variety of positions in uniformed and civilian service for the Army and Navy and other branches of the Government's activities in connection with the war, as well as for indirect service for manufacturers and contractors engaged in war work. This service is about to be turned over to the Engineering Council, which will hereafter conduct the work through its American Engineering Service Committee.

To meet the demands the American Engineering Service Committee will assemble in its offices in the Engineering Societies Building the extensive lists and detailed information collated by the societies. The contribution from our Society is the card index compiled by the Committee on Engineering Resources, Mr. George J. Foran, Chairman, from the Personal Classification Sheets sent in by the members.

The American Engineering Service Committee desires to take this opportunity of calling attention to the fact that if these lists are to be maintained in the most useful condition to the Government and to the Engineering Council, the committee should receive promptly information concerning each engineer who has *gone into any kind of Government service*, direct or indirect, so that a record may be made on his cards in the committee's office. Members of this Society to whom this request applies are urged to send at once, if they have not already done so, their names, present addresses and occupations in the Government service, with a brief statement as to whether or not they are available for other service. This notification should be made to the Secretary, Mr. Calvin W. Rice, who will forward the information to the American Engineering Service Committee.

Certification of Gages

THE following letter will interest those who coöperated in the steps inaugurated by the Society at its Spring Meeting in Cincinnati, May 1917, to bring about the certification of gages. These steps were reported in the January issue of THE JOURNAL under the heading: Public Meeting of Gage Committee. The negotiations of the Society with the Government in the consummation of this important work were of the most pleasant character, and the Society deems it a special privilege to have been of service in the matter.

NAVY DEPARTMENT

BUREAU OF CONSTRUCTION AND REPAIR

WASHINGTON, D. C.

TO THE COMMANDANTS AND INDUSTRIAL MANAGERS OF NAVY YARDS AND NAVAL STATIONS, SUPERINTENDING CONSTRUCTORS, ETC.

Subject: Standardization of Gages

1 The Bureau of Construction and Repair designates the Bureau of Standards of the Department of Commerce, Washington, D. C., as the place at which all master and reference gages and standards of measurements are to be certified. This is intended to include all such master and reference gages and standards of measurement as are used for the work coming under the cognizance of the Bureau, both in manufacturing and inspecting.

2 All master and reference gages and standards of measurement used by private manufacturers in carrying out contracts for the Bureau, where certification is called for by the contract, shall be certified by the Bureau of Standards.

3 Where contracts are entered into which require the certification of gages, the following clause should be included in the contract:

> The master and reference gages and standards of measurements, with which are to be compared the gages and measuring instruments used in carrying out this contract, are to be certified by the Bureau of Standards of the Department of Commerce, Washington, D. C.

4 The designation of the Bureau of Standards as indicated above, and the adoption of the clause to be included in contracts where applicable, have been made on the recommendation of the Joint Committee appointed by The American Society of Mechanical Engineers and the Society of Automotive Engineers, with the view of the standardization of practice of the various Departments and Bureaus of the Government.

TAYLOR.

The 1918 issue of the Year Book of the Society is now off the press and will be issued at an early date.

Appeal from Navy Department

THE Navy is still in urgent need of binoculars, field glasses, spy glasses and telescopes. The submarine has so changed naval warfare that more "Eyes" are needed on every ship, in order that a constant and efficient lookout may be maintained. Sextants and chronometers are also urgently required. Heretofore, the United States has been obliged to rely almost entirely upon foreign countries for its supply of such articles. These channels of supply are now closed, and as no stock is on hand in this country to meet the present emergency, it has become necessary to appeal to the patriotism of private owners, to furnish "Eyes for the Navy."

Several weeks ago an appeal was made through the daily press, resulting in the receipt of over 3000 glasses of various kinds, the great majority of which has proven satisfactory for naval use. This number, however, is wholly insufficient, and the Navy needs many thousands more. May I, therefore, ask your cooperation with the Navy, to impress upon your members by announcing the following salient features in connection with the Navy's call:

All articles should be securely tagged giving the name and address of the donor, and forwarded by mail or express to the Hon. Franklin D. Roosevelt, Assistant Secretary of the Navy, care of Naval Observatory, Washington, D. C., so that they may be acknowledged by him.

Articles not suitable for naval use will be returned to the sender. Those accepted will be keyed, so that the name and address of the donor will be permanently recorded at the Navy Department, and every effort will be made to return them, with added historic interest, at the termination of the war. It is, of course, impossible to guarantee them against damage or loss.

FRANKLIN D. ROOSEVELT,
Assistant Secretary of the Navy.

Navy Department, Washington, D. C.

AMONG THE LOCAL SECTIONS

SOME few months ago the Committee on Local Sections discussed ways and means for coördinating the work of the Sections with that of the Meetings and Publications Committees of the Society, with a view to developing the contributions from the Sections to the general meetings and to the publications. As the outcome the Sections Committee suggested to each Section the desirability of appointing sub-committees on papers and on research, to devote special attention to the securing of local papers for Sections which would be available for publication by the Society and to the collection of data regarding local research work in the educational institutions and the industries. To date nine Sections have responded by the appointment of these special sub-committees: Atlanta, Baltimore, Birmingham, Boston, Philadelphia, Los Angeles, New Orleans, St. Louis and San Francisco. As soon as all the Sections are heard from, the full personnel of these sub-committees will be published in THE JOURNAL.

In giving out this suggestion to the Executive Committees, the Committee on Sections realized, of course, that some Sections would probably not find it feasible to secure the results desired in just this way, in which case it left it is a matter for the Executive Committee itself to decide on what plan shall be followed. The main object desired, however, is that each Section shall contribute its share, through the general meetings and the publications of the parent Society, to the benefit of all the other Sections and of the membership generally. One of the mainstays of success of the Society is this idea of mutual service, and our organization is very fortunate in that we have a goodly number of members who derive genuine pleasure from giving a little more than they receive.

SECTION MEETINGS

BUFFALO

[illegible]. At a meeting of the Buffalo Engineering Society and the Buffalo Section of the Society of Automobile Engineers, C. C. Carpenter, Chief Chemist of the United States Light & Heat Co., of Niagara Falls, presented a paper on Electric Storage Batteries, in which he described the construction of the battery, the care it should receive, and the service to be expected of it. He demonstrated by means of diagrams the effect of extremely hot and cold weather on the efficiency of the battery.

February 13. At the fifth general meeting of the Engineering Society of Buffalo, J. E. Freeman, engineer of the Technical Division, Portland Cement Association, delivered an illustrated lecture on Concrete Boats. Mr. Freeman gave a general review of the progress in concrete-boat building from its earliest inception, described some of the interesting work under way at the present time, and discussed various problems entering into the application of reinforced concrete to such construction. He closed with an exhibition of motion pictures, showing concrete boats, both small and large.

February 19. Chairman F. E. Cardullo gave a talk on A Discussion of Manual and Technical Training.

E. B. NEIL,
Section Secretary.

BALTIMORE

January 10. At a joint meeting held under the auspices of the Baltimore Section, the Engineers' Club and the various associations of stationary engineers to discuss the subject of fuel saving, Charles H. Bromley, Mem.Am.Soc.M.E., delivered the main address on How to Get the Most Out of Coal. The speaker advocated the payment of a bonus as an inducement to firemen to do their best work and the employment of labor-union methods for engineers and firemen to enforce their demands.

Other addresses were made by prominent representatives from each of the associations.

January 29. Mr. Henry Adams, Mem.Am.Soc.M.E., presented a paper entitled Some Engineering Experiences, in which he discussed the development of heating and ventilating equipment, with particular reference to its application to public buildings. He traced the progress from the crude rule-of-thumb methods of the original builders of this equipment to the present.

A business meeting followed, at which a number of sub-committees were appointed. Among these was a committee to offer the services of the members of the Baltimore Section of the Society to the Fuel Administrator of Maryland, to assist in suggesting ways and means to improve the efficiency of burning coal.

A. G. CHRISTIE,
Section Secretary.

BOSTON

January 22. A reception-smoker was tendered to President Charles T. Main, preceded by a dinner at which many old-time friends and associates of Mr. Main were present. Short addresses were made by Professor Whipple, of the Boston Society of Civil Engineers, Mr. John R. Freeman, Past-President, Am.Soc.M.E., and Messrs. Desmond Fitzgerald, Lionel S. Marks, Dugald C. Jackson, H. S. Hale and Calvin W. Rice.

Mr. W. H. Balch, War Correspondent of the Boston *Evening Transcript*, gave a stirring address on Engineering the End of the War.

February 5. The Boston Section joined with the Boston A.I. E.E. Section at the Massachusetts Institute of Technology in a meeting at which a paper on The Modern Trend of Education was given by Prof. Walter I. Schlichter, of Columbia University. Among the prominent educators who discussed the paper were Professor Franklin, of Lehigh University; Professor Brozel, of Yale University, and Professor Clifford, of Massachusetts Institute of Technology. The special problems in training for the Army and Navy, as well as for the mercantile marine, munition factories and other industries directly concerned in the prosecution of the war, were covered. Reference was particularly made to the utilization of existing technical schools in New England for the production of a large number of trained men for this purpose.

W. G. STARKWEATHER,
Section Secretary.

CONNECTICUT SECTION

Hartford Branch

February 12. Chairman B. M. W. Hanson gave an interesting talk on The Functioning and Production of Automatic Fire Arms, in which he explained the composition and working qualities of the Vickers machine gun produced at the Colt's Patent Fire Arms Manufacturing Company. He described the method of insuring interchangeability of parts. He also described the method of ascertaining that the limits for tolerances were not so great as to interfere with the functioning of the gun, which method is understood to be new as far as gun manufacture is concerned. Three models are made, one accurately to maximum limits, one accurately to minimum limits and the third to mean dimensions. The parts of these three models are mixed together, and then picked out again indiscriminately to assemble a gun. This gun is tested in every conceivable manner, and it is easily determined whether the results for tolerance are too great in any particular case.

Mr. Hanson was assisted by Mr. Fred T. Moore, the ballistic expert of the Colt Company, who gave an interesting explanation of the functioning of the Vickers gun.

S. F. JETER,
Section Secretary.

CONNECTICUT SECTION

Meriden Branch

January 17. Professor L. P. Breckenridge, Mem.Am.Soc.M.E., delivered a talk on Coal Conservation. As a result of an invitation extended to the factory owners and the engineers and firemen of the town, there were over 250 persons present. It was a meeting which proved that the Branch could be of valuable service to the community.

February 14. Sixty persons attended the meeting on this date, at which Mr. C. E. Rigby, Engineer for the Blackstone Mutual Fire Insurance Company, gave an illustrated lecture on Fire Protection in Manufacturing Plants.

CHARLES N. FLAGG,
Section Secretary.

LOS ANGELES

February 7. Mr. L. D. Gilbert, Mem.Am.Soc.M.E., delivered an illustrated lecture on The Practical Side of Portland Cement Manufacture, in which he described fully the construction and operation of the South-Western Portland Cement Company's plant located at Victorville, Cal.

T. J. ROYER,
Section Secretary.

MILWAUKEE

January 16. Mr. Walter Alexander, Superintendent of Motive Power for the C. M. & St. P. Ry. Co., gave an illustrated lecture on Electric Locomotives on this railroad.

February 13. Mr. E. S. H. Baars, of the Vilter Manufacturing Co., gave an illustrated talk on Cold Accumulators and Their Application to the Refrigerating Industry.

An illustrated address on The Refrigerating Equipments at the United States Army Cantonments was given by Messrs. Alex H. Luedicke and Fred Goes, also of the Vilter Company.

FRED H. DORNER,
Section Secretary.

NEW ORLEANS

January 12. The A.S.M.E. Section participated in an enjoyable smoker held in connection with the Annual Meeting of the Louisiana Engineering Society.

February 11. By invitation, the New Orleans Section participated in the meeting of the Louisiana Engineering Society, at which a paper on Some Notes on Wireless Telegraphy was read by Prof. P. E. Lehde.

E. W. CARR,
Section Secretary.

ONTARIO

January 29. At a meeting held at Toronto, Mr. F. B. Ward, of the John Inglis Company, gave an address on The Influence of Munition Manufacture and Other War Work on Machine Shop Practice. Several prominent members of the Section took part in the discussion.

CHESTER B. HAMILTON, JR.
Section Secretary.

PHILADELPHIA

February 26. Mr. Carl G. Barth, Mem.Am.Soc.M.E., appeared in a somewhat novel rôle, with a paper on the Income Tax, in which, by a thorough mathematical analysis of the Federal Income Tax Law represented graphically in several ways, he clearly set forth the defects of this law. Mr. Barth showed conclusively that if the rates imposed on incomes up to about $10,000 and above $40,000 are at all fair, then the rates imposed between these two limits are decidedly too high, as recognized and partially corrected in the recent amendment offered by Senator Smoot. He also showed that an exemption for any income, however small, is a mathematical absurdity. Theoretically every income should be taxed, but if this is done consistently a tax too small to make it worth while to collect it is yielded. There must therefore be a natural exemption for incomes below a certain point, as provided by the recent legislation.

It is always a matter of interest to note the applications by engineers of some of their principles to the broader problems of life, and, strange to say, it is by such studies that the engineer often receives a greater public recognition. Taylor's work, for instance, is best known in its psychological aspects. Mr. Barth's discussion of the income tax calls to mind that Mr. Hugo Bilgram, another of our prominent Philadelphia engineers, and a man who is usually associated with machine construction, has devoted many years of study to problems of economics, especially causes of and cures for panics.

JOHN P. MUDD,
Section Secretary.

PROVIDENCE

January 2. Mr. Frederick J. Hoxie, Mem.Am.Soc.M.E., delivered an illustrated lecture on the Causes of Rot in Timber.

February 20. An illustrated lecture on Water Power Development in New England was given by Henry I. Harriman, of Chace & Harriman, Boston. Mr. Harriman was largely instrumental in the development of the Connecticut River Power Company and of the New England Power Company, and is therefore well qualified to discuss this subject. Some of the largest hydroelectric plants in the six states east of the Hudson and also in some of the western states were described fully, and the various types of construction used in developing and utilizing water power were illustrated.

Several other meetings were held during the month by the various sections of the Providence Engineering Society.

JAMES A. HALL,
Correspondent.

ST. LOUIS

February 8. Mr. C. B. Lord, Mem.Am.Soc.M.E., delivered a lecture on the Manufacture and Use of Ammunition as Adapted to Present-Day Warfare. Through the courtesy of the Wagner Electric & Manufacturing Company, he exhibited a number of samples of explosives and shells, and described the methods of

their manufacture, as well as their use in the present war. Mr. Lord's talk also covered fully the manufacture and use of large guns, submarines, torpedoes and depth bombs.

E. H. TENNEY,
Section Secretary.

Student Branch Meetings

BUCKNELL UNIVERSITY

February 4. Following a business meeting, Mr. Fred Bauman gave an interesting talk on The Efficiency Engineer.

H. R. PARS,
Branch Secretary.

LEHIGH UNIVERSITY

February 7. A paper on Recent Developments in Artillery was given by J. W. Hogg, '18, in which he described the French low-power and the German high-power guns.

Mr. Boyd E. Keifer, '18, presented a paper on Modern Milling Machine Cutters, in which he described the new form of milling cutter which has been found very successful by the Bethlehem Steel Company. Instead of using the old form with radial teeth the new type has underent teeth; the tooth profile does not pass through the center of the cutter but back of it. The old form pushes the metal down, while the new type actually cuts it. The new type removes 67 per cent more metal and runs 75 per cent faster than the old type.

N. DMYTROW, JR.,
Branch Secretary.

OHIO STATE UNIVERSITY

January 15. The following officers were elected: Paul Bucher, chairman; H. R. Ansel, vice-chairman; F. E. Smyser, secretary; C. L. Smith, treasurer, and A. A. Casey, sergeant-at-arms. Mr. R. L. Dickinson, Industrial Service Secretary of the Columbus Y.M.C.A., gave a talk on the work being done by the engineer and manufacturer among aliens in Columbus. The Secretary presented a report of the Conference of Student Branches at the Annual Meeting.

F. E. SMYSER,
Branch Secretary.

GEORGIA AGRICULTURAL COLLEGE

January 23. Following a short business meeting the following papers were presented: The Hydraulic Ram, by E. W. Dye; Impulse and Reaction Turbines, by George Carpenter; Hydraulic Engines, by Professor Graf; and Types of Rams, by Professor Goldman.

VEAL K. FORD,
Branch Secretary, pro tem.

PENNSYLVANIA STATE COLLEGE

January 22. The following officers for the second semester were elected: F. R. Hoffman, chairman; Mr. Smith, vice-chairman; H. C. Wright, secretary.

Following a short talk by Professor Wood, each member present was presented with a copy of the thesis by H. R. Hammond and C. W. Holmberg which was awarded the Student Prize at the Annual Meeting of the A.S.M.E.

The following resolutions were passed regarding the death of H. R. Hammond, one of the authors of the thesis.

WHEREAS, In the untimely death of H. R. Hammond of the class of 1916, we have lost an active and faithful member of our society, be it

RESOLVED, That we express our highest appreciation of his unselfish and active services in the interests of our society while in college, and especially to record the honor which has come to our local branch because of the work of merit which was recently presented by Messrs. Hammond and Holmberg and which won the coveted prize for the best paper submitted by members of the Student Branches throughout the country, and which was later read at the Annual Meeting of the A.S.M.E. Also be it resolved, as a further mark of our esteem for his excellent character, that these resolutions be spread upon the minutes of the society and a copy be sent to members of his immediate family.

HAROLD C. WRIGHT,
Branch Secretary.

PURDUE UNIVERSITY

January 16. Mr. J. E. Hannum, instructor in mechanical engineering, gave a talk on The Mechanical Features of the Submarine. The two types of undersea vessels, the submarine and the submersible or modern U-boat, were described and their design and construction explained by means of sketches.

CLAUDE S. KEGERREIS,
Branch Secretary.

STEVENS INSTITUTE OF TECHNOLOGY

February 7. Prof. R. M. Anderson, successor to Dr. Alexander C. Humphreys as Honorary Chairman of the Branch, gave an interesting talk on The Future of the Society. Following the talk the Inspection Trip Committee reported that trips had been arranged to visit the Cooper Hewitt and the Colgate Works.

The proposed new constitution for the Stevens Engineering Society was submitted to those present for consideration and will be considered at the next meeting.

LINCOLN V. AQUADRO,
Branch Secretary.

THROOP COLLEGE OF TECHNOLOGY

February 1. At a joint meeting of the Student Branches of the A.S.M.E. and A.I.E.E., Prof. H. Adams delivered a lecture on Engineering in China. Professor Adams lived in China for a number of years and was therefore well qualified to speak on the subject.

RETLA ALTER,
Branch Secretary.

TUFTS COLLEGE

January 23. Mr. M. W. Hogdon, '18, gave an illustrated talk on Aviation and Aeroplanes, in which he described the methods of training aviators in this country and in Europe. He also spoke of the tactics employed by skilled airmen in battling with a foe, the causes of accidents, and the great strides made in increasing the safety of flying.

CHRISTOPHER L. SMITH,
Branch Secretary.

UNIVERSITY OF CALIFORNIA

February 11. A business meeting was held, at which the following officers were elected: F. C. Holman, chairman; E. K. Schulze, vice-chairman; L. M. K. Boelter, secretary, and H. L. Reich, treasurer.

LLEWELLYN BOELTER,
Branch Secretary.

UNIVERSITY OF CINCINNATI

February 1. Mr. E. W. Roberts, a Cincinnati aeroplane expert, delivered an illustrated lecture on The History of Flight, describing in detail one of the early types of balloons and other flying contrivances. One of the first English aeroplanes (built by Hiram Maxim) the speaker assisted in building, and he told many interesting facts about its construction, comparing it with the more modern machines.

C. L. KOEHLER,
Branch Secretary.

UNIVERSITY OF COLORADO

February 7. At a meeting of the combined branches, an interesting talk was given on Explosives by Mr. Skinner, General Manager of the Western Chemical Works. A division of the R.O.T.C. has been organized at the University and practically every member of the Branch has joined.

H. O. CROFT,
Branch Secretary.

UNIVERSITY OF ILLINOIS

In the early part of the college year the Student Branch, representing the Mechanical Engineering Department, gave a very instructive Mechanical Engineering Show.

At the second meeting of the Branch, Mr. Godeke, instructor in mechanical engineering, delivered a lecture on Equipment of the Power Laboratory. Opportunities in connection with the Student Branch were discussed by Mr. Radebaugh.

The subject of the November meeting was Airplane Engines, the speaker being Capt. L. Simpson of the School of Military Aeronautics.

At the December Meeting, Mr. B. S. Day, instructor in the power laboratory, spoke on Our Laboratory, Old and New. The Branch also held a smoker during the month which was well attended.

J. J. Kalivoda,
Branch Secretary.

UNIVERSITY OF MISSOURI

January 15. A paper was presented by L. N. Thompson on Recent Developments in the Design of Aeroplane Engines.

J. W. Baldwin,
Branch Secretary.

UNIVERSITY OF NEBRASKA

February 5. The Diesel Engine was the subject of the meeting and was discussed in a paper by Mr. F. W. Rabe, who spent some time in Germany before the war and had inspected several of the Diesel factories. In addition to bringing out the advantages and disadvantages of the Diesel engine, Mr. Rabe also spoke about the life of the inventor and the many obstacles he encountered in selling his patents.

Professor Seaton brought out a fact of interest that the Germans have perfected a Diesel engine actually light enough to be of practical use as a prime mover for aeroplanes.

W. L. Millar,
Branch Secretary.

UNIVERSITY OF OKLAHOMA

January 15. At a joint meeting of the A.I.E.E. and A.S.M.E. Branches the following papers were presented: The Election, by Professor Tappen; Large Types of Steam Boilers, by Professor Helmrick—of especial interest since the speaker had recently returned from Detroit where the largest boiler of today is located; Some Large Power Plants in New York, by Dean Felgar; and Frequencies, by L. B. Holland.

Paul B. Stockwell,
Branch Secretary.

UNIVERSITY OF WASHINGTON

The university is coöperating with the Government by having a Reserve Officers' Training Corps in which underclassmen receive eight hours of training a week with upperclassmen as officers and members of the faculty as instructors, the latter being in the R.O.T.C. An A.U.S. Naval Training Station is located on the campus with an enrollment of about a thousand and a course for marine operating engineers under the direction of the U. S. Shipping Board is given by the mechanical engineering faculty to men from all over the West and Southwest. Over a thousand men from the University of Washington are now in the service, and a good share from the engineering school are now in various branches of the Engineering Corps and other branches of service.

January 17. The meeting was held to discuss plans for a smoker. It was also voted to procure a service flag for the Mechanical Engineering Department at the University.

February 6. Wooden Ship Building and Development, and the Use of the Semi-Diesel Engine in Wooden Ships was the subject on which Mr. R. M. Dyer, Mem.Am.Soc.M.E., gave a most interesting talk. The Diesel Engine was also discussed by Mr. J. M. Royal, Jun.Am.Soc.M.E.

Mr. Anderson, of The American Blower Company, made an address on the Value of a College Education.

H. B. Sallee,
Corresponding Secretary.

UNIVERSITY OF WISCONSIN

January 24. The following were elected officers for the second semester: George Moore, chairman; Glenn Warren, vice-chairman; W. Mantonya, secretary, and K. Seelback, treasurer. An amendment was made to the Student Branch Constitution whereby a fine would be imposed upon the members for absence from a meeting.

K. G. Shiels,
Branch Secretary.

VIRGINIA POLYTECHNIC INSTITUTE

January 24. The meeting was devoted entirely to business matters, including planning the conduct of future meetings and the election of C. H. Driskill as chairman, to succeed Mr. Kearsley.

E. W. Digges,
Branch Secretary.

WORCESTER POLYTECHNIC INSTITUTE

January 11. At the Joint Meeting of the Student Engineering Societies, held under the auspices of the Civil Engineering Society, S. G. Webb, engineer with the Gypsum Industry Association, gave an interesting and valuable talk on the Use of Gypsum in Building Construction. He first explained what gypsum was from the chemist's viewpoint, calling attention to its commonly used name in the arts of plaster of paris and in its use in agriculture under the name of plaster, and then described the sources from which it is procured, its manufacture and finally its use in the building trades. Interesting points brought out were the adaptability of this material to construction of all sorts, its great fire-resisting qualities, its low sound-transmitting quality and its use as a heat-insulating material.

February 6. The resignation of Chairman R. C. Lewis was accepted, owing to his enlistment in aviation work. Mr. Chenoweth Housum, Engineer for the Jefferies-Norton Company, gave a talk on Some Large Gas-Engine Installations, reviewing the merits of the two- and four-cycle types of gas engines. The fuels used in large gas engines such as natural gas, coke-oven gas, blast-furnace gas and producer gas were considered in detail and problems to be overcome in using these fuels were cited. The advantages gained by the use of gas engines over steam engines for blowing in steel mills and blast-furnace work were also touched upon.

H. P. Fairfield,
Branch Secretary.

The Association of Eleventh Engineers (Ry.) has been formed to promote the welfare of the 11th Engineers (Ry.), U. S. A.

This regiment is the one which was recruited entirely by the Military Engineering Committee of the Engineering Societies. The regiment was in the fighting at Cambrai, where it gained the prompt praise of both British and French generals, and earned the name of "The Fighting Engineers."

The Association will be glad to receive from engineers, contributions for carrying on its manifold aims and activities, all of which center to the underlying purpose of service to the men of the 11th Engineers. Mr. J. Waldo Smith, Mem.Am.Soc.M.E., is chairman of the Finance Committee and Mr. Robert Lynn Cox is treasurer, to whom contributions should be sent at the Metropolitan Life Building, No. 1 Madison Ave., New York City.

Sir John Wolfe Wolfe-Barry, one who, by his most varied ability, wide experience, sound judgment and untiring energy, represented the highest traditions of the engineering profession, died on January 22 in his eighty-second year. Sir John will perhaps best be remembered by the engineering societies in this country for his valuable work in connection with the British Engineering Standards Committee. This work inspired the standardization movement among the engineering societies here, which led to the establishment of the American Engineering Standards Committee. This committee now aspires to do the same valuable work for American engineering that the British committee has done for British practice.

Those members of the Society who are interested in this standards work would do well to refer to Sir John's lecture on The Standardization of Engineering Materials and Its Influence Upon the Prosperity of the Country, delivered as the James Forrest Lecture before the Institution of Civil Engineers in 1917, and published in London *Engineering*, vol. ciii, p. 432. His lecture contains a great mass of valuable and interesting information.

NINTH ROLL OF HONOR

MEMBERS of the Society can note with pride how our Roll of Honor is steadily lengthening—this in spite of the fact that the everyday work of a large number of the members is a patriotic service in itself. The call to arms appears to be irresistible and the response unhesitating:

ALEXANDER, W. P., Captain, Inspection Division, Ordnance Department, United States Army.

ALLEN, HENRY A., Colonel Commanding 108th Engineers, 33rd Division, Camp Logan, Houston, Tex.

ANDERSON, F. C., Captain, Engineers' Reserve Corps, Metuchen, N. J.

ATTERBURY, W. W., Brigadier-General, Director General of Transportation, American Expeditionary Forces, France.

BARTON, RAYMOND L., First Lieutenant, Ordnance Officers' Reserve Corps, United States Army.

BEEN, PAUL, Corporal, 9th Engineer Train, Courchesne Bridge, El Paso, Tex.

BERGES, ARTHUR H., Sergeant, First Battalion Headquarters, 23rd Engineers, American Expeditionary Forces, France.

BEVIN, SYDNEY, Captain, Ordnance Officers' Reserve Corps, Detached Service.

BLUMENFELD, R., Lieutenant, Ordnance Officers' Reserve Corps, Production Section, Carriage Division, Washington, D. C.

BORNHORST, A. H., First Lieutenant, Signal Officers' Reserve Corps.

BOOTHMAN, DALE M., First Lieutenant, Ordnance Officers' Reserve Corps, Engineering Bureau, Trench Warfare Branch, Washington, D. C.

BORDEN, JOHN M., Second Lieutenant, Ordnance Officers' Reserve Corps.

BREEDLOVE, L. B., First Lieutenant, Ordnance Officers' Reserve Corps, United States Army.

BRYAN, MARCUS K., Lieutenant, Ordnance Officers' Reserve Corps.

CHURCH, F. O., First Lieutenant, Company B, 26th Engineers, American Expeditionary Forces, France.

CLARKE, LEON L., American Expeditionary Forces, France.

COOLEY, M. E., Lieutenant Commander, Michigan Naval Brigade, Ann Arbor, Mich.

COOPER, HUGH L., Major, Engineer Officers' Reserve Corps, American Expeditionary Forces, France.

CORY, HARRY THOMAS, Major, Engineer Officers' Reserve Corps (unassigned).

CROSBY, W. W., Lieutenant-Colonel, 104th Engineers, Camp McClellan, Ala.

CULLEN, JAMES W., Signal Corps, United States Army.

DAVIES, T. R., First Lieutenant, Ordnance Officers' Reserve Corps, Carriage Division, Field Artillery Section, Ordnance Department, United States Army.

DAVIS, CALVIN E., Second Lieutenant, Aviation Section, Signal Officers' Reserve Corps.

DUFFY, FRANK J., Major, 103rd Regiment of Engineers, United States Army.

DUVENECK, FRANCIS B., Master Signal Electrician, 322nd Field Signal Battalion, United States Army.

EHRHARDT, JOHN J., Captain, Ordnance Department, United States Army.

EYRE, THOMAS T., Captain Engineers, United States Reserve, Commanding Company E, 113th Engineers, Camp Shelby, Miss.

FLICKINGER, HARRISON W., First Lieutenant, Signal Officers' Reserve Corps, Aviation Section, United States Army.

FOGG, OSCAR H., Captain, Officers' Reserve Corps, United States Army.

FORTNEY, C. P., Captain, Engineers, United States Reserve, Washington, D. C.

FULLER, FLOID M., Lieutenant, Reserve Force, United States Navy.

GARRETT, SEYMOUR S., Captain, Engineer Officers' Reserve Corps (Unattached), American Expeditionary Forces, France.

GATLEY, W. A., First Lieutenant, Ordnance Officers' Reserve Corps, Rock Island Arsenal, Ill.

GIEBEL, ROBERT L., Second Lieutenant, Ordnance Officers' Reserve Corps.

GRAVES, RALPH L., Captain, Field Artillery Section, Carriage Division, Ordnance Department, Ordnance Officers' Reserve Corps, United States Army.

HALL, ROLAND B., JR., Captain, Engineer Officers' Reserve Corps, France.

HAWES, ALEXANDER G., Captain, Ordnance Officers' Reserve Corps, United States Army.

HAYES, WILLIAM PARSONS, Lieutenant, Fleet Naval Reserve, assigned to U. S. S. Niagara.

HILL, REUBEN, Major, Ordnance Officers' Reserve Corps, Office of Chief of Ordnance, Washington, D. C.

HIRSHFELD, CLARENCE F., Major, Ordnance Officers' Reserve Corps, United States Army.

HOFFMAN, ROSCOE C., Captain, Ordnance Officers' Reserve Corps, Motor Equipment Section, Carriage Division, Washington, D. C.

HUNTER, HERBERT C., First Lieutenant, Trench Warfare Branch, Engineering Bureau, Ordnance Officers' Reserve Corps.

LEWIS, GOODRICH Q., Ensign, United States Naval Reserve Force.

LISKOW, B. H., Captain Engineers, United States Reserve.

LOCKARD, JAMES P., Second Lieutenant, 328th Field Artillery, Officers' Reserve Corps, Camp Custer, Battle Creek, Mich.

LORING, ERNEST J., Captain, Ordnance Officers' Reserve Corps, Design Section, Trench Warfare Branch, Gun Division.

LYNE, LEWIS F., JR., First Lieutenant, Ordnance Officers' Reserve Corps, Inspector of Ordnance.

MACARDELL, WESLEY E., Department of Engineers, U. S. Military Academy, West Point, N. Y.

MACEWAN, THOMAS S., Aviation Section, Signal Enlisted Reserve Corps.

MARDAGA, LOUIS, Ensign, United States Naval Reserve Force.

MARTIN, ELMER C., Engineer Officers' Training Camp, 7th Company, Camp Lee, Petersburg, Va.

MAURY, DABNEY H., Major, Engineer Officers' Reserve Corps, Office Cantonment Constructor, Washington, D. C.

MAXFIELD, HOWARD H., Lieutenant, Colonel 19th U. S. Engineers, American Expeditionary Forces, France.

MINICH, HENRY D., First Lieutenant, Ordnance Department, United States Army.

O'CONNELL, JOHN J., Captain, Ordnance Officers' Reserve Corps, United States Army.

PARK, J. FRANK, JR., 12th Engineers, Railway, H. O. Detachment, American Expeditionary Forces, France.

PETERS, CLIFFORD H., Lieutenant, Ordnance Officers' Reserve Corps.

PICCARD, J. E., Captain, United States Army, Corozal, Canal Zone.

POHLE, R. F., First Lieutenant, Production Officer, Ordnance Officers' Reserve Corps.

PULLEN, ROYAL R., First Lieutenant, 364th Infantry, Reserve Corps, Camp Lewis, Wis.

RENTON, J. LEWIS, Captain, Company G, First Regiment Hawaiian Infantry, National Guard, Erva, Hawaii.

REUTER, FRANCIS J. G., First Lieutenant, 7th Coast, Engineer Reserve Officers' Training Camp, United States Reserve.

RIDER, JOSEPH B., 2nd, Company E, 10th Engineers (Forestry), American Expeditionary Forces, France.

RITTER, E. R., First Lieutenant, Ordnance Officers' Reserve Corps.

ROLAND, P. W., Naval Aviation Corps.

RUGG, DANIEL M., 307th Engineers, United States Army.

SAGE, DARROW, Lieutenant, N. M. Y., United States Navy, U. S. S. Missouri.

SANDERS, WALTER C., Lieutenant, Coast Artillery Reserve Corps, United States Army.

SEATON, ROY A., Captain, Ordnance Officers' Reserve Corps, United States Army.

SELLMAN, NILS T., Engineer, Coast Artillery National Guards, United States Army.

SEYBOLD, EUGENE, First Lieutenant, Ordnance Officers' Reserve Corps, Watervliet Arsenal, Watervliet, N. Y.

SHATTUCK, CHARLES H., First Lieutenant, Ordnance Reserve Corps, United States Reserve.

SHUSTER, M. M., Naval Aeronautic Branch, Naval Air Station, Pensacola, Fla.

SLOAN, BEN, Captain, Ordnance Officers' Reserve Corps, Inspector of Ordnance, United States Army.

STRAUSS, JEROME, Lieutenant, Inspector of Ordnance, Ordnance Department, United States Reserve.

SWINBURNE, JAMES G., First Lieutenant, Ordnance Officers' Reserve Corps, United States Army.

UNDERHILL, CHARLES R., Captain, Aviation Section, Signal Reserve Corps.

VEHSLAGE, HAROLD E., First Lieutenant, Procurement Division, Ordnance Department, United States Army.

VOGT, CLARENCE W., First Lieutenant, Ordnance Department, U. S. R., Frankford Arsenal.

WADSWORTH, GEORGE R., Major, Engineer Officers' Reserve Corps, United States Reserve.

WANDEL, CARLTON, First Lieutenant, Ordnance Department, American Expeditionary Forces, France.

WILFERT, GEORGE, Captain, Ordnance Officers' Reserve Corps, United States Army.

WILKINS, CHARLES N., Aviation Section, Signal Enlisted Reserve Corps.

WOODS, SAMUEL H., Captain, Engineering Section, Quartermaster Corps, United States Army.

PERSONALS

In these columns are inserted items concerning members of the Society and their professional activities. Members are always interested in the doings of their fellow-members, and the Society welcomes notes from members and concerning members for insertion in this section. All communications of personal notes should be addressed to the Secretary, and items should be received by March 16 in order to appear in the April issue.

CHANGES OF POSITION

Gilbert G. Weaver, formerly director of the Coöperative Industrial School, York, Pa., has assumed the duties of director of the Dayton Industrial Institute, Dayton, Ohio.

H. Hamilton Weber has left the lubricating division of the Texas Company in New York, and has joined the efficiency department of the Hyatt Roller Bearing Company, of Newark, N. J.

James A. Campbell has resigned his position with the Renfrew Manufacturing Company, Adams, Mass., as mechanical superintendent, and has taken a similar position with Lever Brothers, Cambridge, Mass.

Charles A. Haynes, until recently superintendent of the Mohegan Tube Works, Brooklyn, N. Y., has assumed the duties of production engineer with the British Ministry of Munitions in the United States.

James Brakes, Jr., has resigned his position as power plant inspector for the Western Electric Company, Chicago, Ill., to accept the position of draftsman for the Gamm Bernstein Motor Truck Company, Lima, Ohio.

Martin Newcomer, formerly production manager of the American Player Action Company, New York, has become affiliated with the U. S. Cartridge Company, Lowell, Mass., as engineer in charge of shell waterproofing.

John F. Guthrie, formerly associated with the Arnold Print Works, of North Adams, Mass., in the capacity of mechanical engineer, has accepted a similar position with The Abrasive Company, of Bridesburg, Philadelphia, Pa.

Carl T. Carlson has resigned his position with the Springfield Boiler and Manufacturing Company, of Springfield, Ill., as chief engineer, and has accepted the position of combustion engineer for the City of Gothenburg, Sweden.

Earl B. Morgan has resigned as safety engineer for the Norton Company to take the position of safety engineer with the Liberty Mutual Insurance Company, of Boston, Mass. Mr. Morgan will take up his new duties March 1.

Frederick W. Burger has left the employ of the Delphos Manufacturing Company, Delphos, Ohio, to accept the position of assistant to the superintendent of the experimental department of the International Harvester Corporation, Chicago, Ill.

Harold E. Smock has resigned his position as chief draftsman of the Cohoes Rolling Mill Company, Cohoes, N. Y., subsidiary concern of the Page-Hersey Iron, Tube and Lead Company, of Toronto, Canada, to enter the Ordnance Department at Washington, D. C.

Melvin B. Newcomb is no longer connected with the special engineering department of the Firestone Tire and Rubber Company, Akron, Ohio, having assumed the position of chief draftsman of the hydraulic department of the Wellman Seaver Morgan Company, Cleveland, Ohio.

John H. Romann, until recently works engineer with the American Steel Foundries, Indiana Harbor, Ind., has become associated with the export department of J. T. Ryerson and Son, Chicago, Ill. Mr. Romann will leave for Europe in July as representative of the Ryerson Company for the Latin countries of Europe.

Frederick A. Barnes, for nine years with George S. Rider and Company, consulting engineers, Cleveland, Ohio, and for the past year in charge of the office, has severed his connection with that firm and is at present in Washington, in the quartermaster-general's office, engaged in the design of standardized shops for repairing military trucks.

Oliver M. Davis has left the employ of Swift and Company, with whom he was connected for the past six years, giving up his position of general superintendent of oil mills, Columbia, S. C., to take up work in connection with the Government's program for the building of fabricated ships, with headquarters at the Whitehead and Kales Iron Works, Detroit, Mich.

ANNOUNCEMENTS

M. E. Gould has become associated with the Covert Gear Company, of Lockport, N. Y.

John Calder has been made vice-president and general manager of the Aero Marine Plane and Engine Company, Keyport, N. J.

John B. Matthews has become affiliated with the Moore and Scott Iron Works, Oakland, Cal., in the capacity of engineer.

Joseph Wilcox, Jr., has entered the service of the Fitchburg Grinding Machine Company, Fitchburg, Mass., in the capacity of chief draftsman.

Greetings have been received from the front from our member, **P. G. Welford**, of the Canadian Field Artillery, in the form of an attractive card issued by the Fourth Canadian Division.

Louis Mardaga has entered the naval service in the capacity of Ensign, U. S. N. R. F., and is at present located as assistant naval inspector of ordnance, Alloy Steel Forging Plant, Carnegie, Pa.

John C. Mahoney, formerly connected with the General Electric Company at Atlanta, Ga., as district turbine inspector, has become associated with the Schenectady office of the same company.

Carl G. Barth, consulting management engineer, of Philadelphia, has been given a special commission in the matter of extending costs investigation for the Watertown Arsenal, Watertown Mass.

F. J. Hull, who was associated with the Pangborn Corporation as engineer, about five years ago, and more recently in the employ of the Mott Sand-Blast Company, has returned to the Pangborn Corporation in the capacity of assistant engineer.

Fred V. Hadley has resigned as chief engineer of the American Incandescent Heat Company, Boston, Mass., and has opened an office in Boston, Mass., for general consulting work, specializing in heat-treatment engineering and industrial-furnace design.

Robert L. Hibbard has resigned his position as assistant manager and gas engineer of the Riter-Conley Company, Pittsburgh, Pa., with which firm he was connected for the past 15 years, and has opened engineering offices in the Jenkins Arcade Building, Pittsburgh, Pa.

Joseph Esherick, of Philadelphia, Pa., has become associated with the Baker-Dunbar-Allen Company, which, under Mr. Esherick's personal supervision, will represent the D. Connelly Boiler

[illegible] The [illegible]boro Company, and the [illegible] Instrument Company.

JOHN W. L. BENNETT, after eight years of service with the City of New York, first as deputy commissioner of water supply and later as consulting engineer, announces that he is now associated with Ernest P. Goodrich and A. Pearson Hoover, consulting engineers, with offices at 261 Broadway, New York.

CAPT. CLARENCE W. VOGT was commissioned a First Lieutenant Ordnance Department, U. S. R., June 11, 1917, and was ordered to the Frankford Arsenal at Philadelphia, Pa., August 1. He was promoted to the grade of Captain Ordnance, U. S. N. A. January 22, 1918, and is in charge of the artillery primer shops at the Frankford Arsenal.

CHARLES S. HAMNER and HOWARD P. QUICK, who have been associated for some time in engineering inspection and appraisal work in New York, have taken over the engineering and sales

C. S. FOLLER

management of the Parson Manufacturing Company's system of fuel-burning apparatus and ash ejectors for power plants, ships and factory heating plants, with offices at 165 Broadway, New York.

L. H. BERGMAN, until recently fuel engineer for the Midvale Steel Company, Philadelphia, Pa., and J. W. Lauren, formerly vice-president of the Reynolds Wire Company, Dixon, Ill., have incorporated the American Industrial Engineering Company with offices in the Monadnock Building, Chicago, Ill., and will specialize on wire-mill equipment, pulverized-fuel installations, furnace work and fuel economy.

APPOINTMENTS

WILLIAM PARSONS HAYES has been appointed a Lieutenant in the Fleet Naval Reserve and assigned to the *U. S. S. Niagara*.

DAVID H. RAY has been appointed director of the Laboratory, U. S. Signal Corps School National Army, at the College of the City of New York.

NECROLOGY

WILLIAM L. DIERMAN

William L. Dierman was born on May 19, 1868, in Ghent, Belgium. He was educated in the College of Toulouse, France, and the College of Richmond, in London, England. In 1887 he received the degree of C.E. from Ghent University and in 1888 the degree of E.E. from the Montefiore Institute, Liège, Belgium.

Upon the completion of his engineering course he became associated with the Société Générale Electrique and was located first in Paris and afterward in Lille, France. It was while with the Société that he had charge of the building of tramways in European Russia and the Caucasus.

He was next connected with the Société Eclairage et Transmissions Electriques a Longe Distance, where his duties at first [illegible]

In 1890 he was commissioned by the Belgian Government to make a report on the electric traction of the United States. In 1891 he was made supervising engineer of the electric-traction department of the Compagnie Internationale d'Electricité, Liège. He was the designer of the electric-traction system of the Liège and Herstal Street Railway and of many other minor systems. He was the supervisor of the installation of the electric system in Liège. From 1893 to 1901 he was general manager of the concern of Dierman & Co., Liège, which later became the Société des Applications de l'Electricité in Liège. In 1901 he located in Brussels, where he acted as consulting engineer for the Compagnie Générale de Construction, Paris, Ateliers Rateau Muysen-Malines, and Ateliers de Construction de Blanc Misseron, designing electrical and mechanical plants for these companies.

Since the war he has been purchasing manager in New York for the Eclairage Electrique of Paris. In this connection he directed the purchase of machine tools and machinery for new works in France. He was the Administrateur Delegue for Belgium of his concern. He also maintained a private office as consulting engineer in Brussels.

Mr. Dierman was a member of the Société des Ingénieurs Civils de France. He became a member of the Society in 1915. He died on December 25, 1916.

GEORGE LELAND FALES

George L. Fales was born on May 18, 1878, in Nashua, N. H., and was educated in the grammar and high schools there. His technical education he obtained through self-study.

For two years he was in charge of the power plant of the Bayley Hat Manufacturing Co., Newburyport, Mass. His next position was with the G. R. & I. St. Ry. Co., Georgetown, Mass., as chief engineer of its 1200-hp. power plant. In September 1899 he was made chief mechanical engineer of the Boston Almshouse and Hospitals, Boston, Mass. In 1904 he resigned to take the

W. L. DIERMAN

position of chief engineer and electrician with the Great Northern Portland Cement Co., Marlborough, Mich., where he had charge of the power plant and mill equipment of motors, air compressors, etc. The following year he became connected with the Hudson Portland Cement Co., Hudson, N. Y., as chief engineer and electrician, having charge of the power plant and electric equipment. In February 1906 he was made superintendent of the power department of the Tennessee Copper Co., Copperhill, Tenn., having charge of all power plants of the company, aggregating 10,000 hp. in steam, electric, compressed-air and refrigerating machinery. In 1916, after ten years with the Tennessee Copper Co., he resigned to take the position of chief engineer with the Raritan Copper Works, Perth Amboy, N. J., which position he was holding at the time of his death.

Mr. Fales was a master operating engineer, a member of the Institute of Operating Engineers, and a member also of the National Association of Stationary Engineers. He became an associate-member of the Society in 1914. He died on December 29, 1917.

CHARLES S. FOLLER

Charles S. Foller was born in Buffalo, N. Y., on May 9, 1876. He attended the public schools of that city, and upon being graduated from the high school went to Hobart College, Geneva, N. Y., for a year. He also took special work in Cornell University.

He served an apprenticeship of one year at the machinist's trade with the Lake Shore & Michigan Southern Railway. He was then employed in the drafting room of the Brooks Locomotive Works, Dunkirk, N. Y., afterward accepting a position with the Pittsburgh Locomotive Works as chief draftsman, shortly being advanced to superintendent of frame work in the shops. From 1897 to 1905 he was connected with the designing department of the American Locomotive Co., and at the close of that period was the principal designer of new locomotives of the company. For about a year he was engaged in designing steel cars with the Standard Steel Car Co., Pittsburgh, Pa. For the last twelve years Mr. Foller has been associated with the Union Spring & Manufacturing Co., Pittsburgh, Pa., first as mechanical engineer and then as western sales manager, in charge of the office in St. Louis, Mo. In the summer of 1913 he returned to the headquarters of the company at Pittsburgh as general manager of sales.

Mr. Foller was a member of the Engineers' Society of Western Pennsylvania and the American Society of Testing Materials. He became a member of our Society in 1906. He died in Pittsburgh on December 30, 1917.

EDWARD McKIM HAGAR

Edward M. Hagar was born on June 21, 1873, in Salem, Mass. He was graduated from the Massachusetts Institute of Technology in 1893 with the degree of M.E., and in 1894 received his M.M.E. from Cornell University.

The following year he was employed by the North and West Chicago Street Railroad in their electrical-engineering department. In 1895 he became manager of the Chicago office of the Southwark Foundry & Machine Company, and in 1898 founded the firm of E. M. Hagar & Co., western agents for a number of firms handling engines and machinery. In 1899 he was appointed manager of the cement department of the Illinois Steel Co. In 1904 Mr. Hagar became president of the Universal Portland Cement Co., a subsidiary of the U. S. Steel Corporation, and in 1916 president of the Wright-Martin Aircraft Corporation and the Simplex Automobile Co The following year he was elected president of the American International Steel Corporation.

Mr. Hagar was a member of the American Society of Civil Engineers and of many clubs. He joined our Society in 1895. He died on January 18, 1918.

O. ZELL HOWARD

O. Zell Howard was born in Raleigh, N. C., on December 6, 1876. He was graduated from Lehigh University with the class of 1896, and during the next year was employed in the shops of the Crawford Mfg. Co., Hagerstown, Md.

His drafting-room experience he obtained with the Newport News Shipbuilding and Dry Dock Co., where his work dealt with marine-engine and boiler drafting. His next position was with the Baltimore Smelting and Refining Company on general machine drafting. In 1900 he turned again to marine-engine and boiler drafting with the Maryland Steel Co., Sparrows Point, Md. For about a year he was connected with the Bureau of Construction and Repair, Navy Department, Washington, D. C., on auxiliary machinery, resigning to take the position of mechanical engineer with the American Carbide Lamp Co., Philadelphia, Pa. In 1902 he became an instructor in the department of marine engineering and naval construction in the United States Naval Academy, Annapolis, Md. He assisted the head of the department in preparing textbooks on naval engines and machinery and on mechanical processes. He also assisted in the laying out and the superintending of the erection of experimental turbines and boilers in the Naval Experiment Station at Annapolis, and in making tests on the machinery already erected. For the last three years he has been supervising engineer of the Diamond Match Co.

Mr. Howard was a member of the American Society of Civil Engineers, the American Institute of Electrical Engineers and the Society of Naval Architects and Marine Engineers. He became a member of our Society in 1908. He died on December 20, 1917.

CHARLES D. PARKER

Charles D. Parker was born in 1858 in Worcester, Mass. He was educated in the public schools of that city and later attended Worcester Polytechnic Institute, being graduated with the class of 1879.

His first position was with the Crompton Loom Works at Worcester, where he worked at patternmaking for about six months. For the next year and a half he was in the drafting room, and at that time took charge of the patternmaking and drafting departments.

For the last fifteen years he was mechanical expert of the A.

O. Zell Howard

Burlingame Co., Worcester, Mass., builders of steam engines and sawmill outfits.

Mr. Parker became a member of the Society in 1886. He died on December 7, 1917.

GERALD EDGAR TERWILLIGER

Gerald E. Terwilliger was born on January 9, 1888, in Newark, N. J. He received his early education in the Barringer School, Newark, and entered Stevens Institute of Technology in 1905, from which he was graduated in 1909.

For the next two years he studied law and in 1911 was admitted to the bar of New York State. He specialized in patent law, where his technical training made him very successful. In addition to his legal profession, Mr. Terwilliger was interested in literary work, writing for newspaper and magazine publications. He was the editor of the *Stevens Indicator*, an alumni publication of Stevens Institute.

He became a junior member of the Society in 1910. He died on December 9, 1917.

CANDIDATES FOR MEMBERSHIP

TO BE VOTED ON AFTER APRIL 10

BELOW is the list of candidates who have filed applications since the date of the last issue of THE JOURNAL. These are classified according to the grades for which their ages qualify them, and not with regard to professional qualifications, i.e., the ages of those under the first heading place them under either Member, Associate or Associate-Member, those in the next class under Associate or Associate-Member, those in the third class under Associate-Member or Junior, and those in the fourth under Junior grade only. Applications for change of grading are also posted. Total number of new applications, 134.

The Membership Committee, and in turn the Council, urge the members to scrutinize this list with care and advise the Secretary promptly of any objections to the candidates posted. Any correspondence in this regard is strictly confidential. Unless objection is made to any of the candidates by April 10, and providing satisfactory replies have been received from the required number of references, they will be balloted upon by the Council. Those elected will be notified about May 15.

NOTE. The Council desires to impress upon applicants for membership that under the present national conditions the procedure of election of members may be slower than under normal conditions.

NEW APPLICATIONS

FOR CONSIDERATION AS MEMBER, ASSOCIATE OR ASSOCIATE-MEMBER

California

LIGHT, ARTHUR H., Chief Engineer, American Beet Sugar Co., Oxnard

UDALL, PHILLYS A., Chief Inspector, Holt Manufacturing Co., Stockton

WADE, FRANKLIN S., Supt. of Operation, Southern Counties Gas Co. of Cal., Los Angeles

Connecticut

STYER, OLIVER S., Chief Inspector, Pratt & Cady Co., Inc., Hartford

District of Columbia

FRYER, ROSS L., Consulting Engineer, Washington

GILL, JOSEPH R., Mechanical Supt., U. S. Department of Agriculture, Washington

GOODWIN, PERCY F., Captain, Engineers, U. S. R., Washington

HEINE, GREGOR H., Instructor in M. E., Catholic University, Washington

MARTIN, HARRY T., Captain, Ordnance Reserve Corps, U. S. Army, Washington

Georgia

BUSSEY, HENSON E., District Engineer, General Electric Co., Atlanta

Illinois

ARNOLD, DOUGLASS L., Chief Engineer, International Harvester Corp., Chicago

BRIGGS, WALTER B., District Manager, Shepard Electric Crane & Hoist Co., Chicago

DERROM, DONALD L., Works Manager, Munitions Department, Winslow Bros. Co., Chicago

HENSCHEL, OTTOMAR H., Associate Editor Technical Publishing Co., Chicago

O'CONNOR, JEREMIAH J., Chief Engineer Fenger High School, Chicago

ROBINSON, WILLIAM A., Secretary and General Manager, Charter Gas Engine Co., Sterling

RULE, PERRIN, Superintendent, Iroquois Iron Co., South Chicago

SMITH, WILLIAM P., General Superintendent, The Frost Manufacturing Co., Galesburg

Indiana

SNYDER, LEWIS A., Consulting Engineer, Studebaker Corp., Indianapolis

Iowa

SAYRE, HERBERT A., Coal Operator, Treasurer, Eagle Coal & Mining Co., Des Moines

Kansas

GREENFIELD, BENJAMIN, Engineer, Steam Power Dept., Empire Gas & Fuel Co., El Dorado

Louisiana

COULETTE, JEFFERSON D., Construction Engineer and Plant Superintendent, Gulf Refining Co., and Gypsy Oil Co., Shreveport

Massachusetts

MERRILL, MELDON H., Vice-President, Tennessee Eastern Electric Co., Boston

SAWYER, HARRY S., Assistant Works Manager, Wiley & Russell Division, Greenfield Tap & Die Corp., Greenfield

SKENTELBERY, CHARLES, Marine Superintendent, New England Fuel and Transportation Co., Boston

WILDER, CARL D., Assistant to the Superintendent, Reed Prentice Co., Worcester

Michigan

ERICKSON, JOHN, Electrical and Mechanical Engineer, Engberg's Elec. & Mech. Wks., St. Joseph

LUND, MATTHEW, Vice President and General Manager, Valley City Machine Works, Grand Rapids

Missouri

KOHN, NATHAN, Owner of The R. K. Engineers, St. Louis

NUTTING, FRANK S., Testing Engineer, Busch Sulzer Bros. Diesel Engine Co., St. Louis

New Jersey

BALDWIN, CHARLES M., Assistant Inspector of Machinery, U. S. Navy, B. & W. Company, Bayonne

KERR, HOWARD J., Assistant to General Superintendent, Babcock & Wilcox Co., Bayonne

REESE, LAURITS A., Superintendent, Jobbing & Tool Service Division, Edison Phonograph Works, West Orange

VOLZ, PHILIP, Mechanical Engineer, Forstmann & Huffmann Co., Passaic

New York

ANTHONY, MARC O., Consulting Engineer, A. Kimball Co., New York

BATES, JOHN R., Vice President, Wonham Bates & Goode, Inc., New York

BROWNELL, LOUIS M., Industrial Engineer, C. E. Knoeppel & Co., New York

CRAMER, SIDNEY R., Cost Estimator, American Locomotive Co., New York

DE VOGE, JOHN D., Foreman of Planning Dept., Watervliet Arsenal, Watervliet

DILTS, FRANK B., President, Dilts Machine Works, Inc., Fulton

HUBER, FRED F., Designing Engineer, C. W. Hunt Co., Inc., West New Brighton

ILTIS, JOHN, Designer and Estimator, Guarantee Construction Co., New York

KENNARD, RALPH B., Chief Draftsman, Niagara, Lockport & Ontario Pr. Co., Lyons

KIP, HENRY E., Engineer, Union Carbide Co., Niagara Falls

NOWLAND, BENONI, Superintendent Brass Department, John Thomson Press Co., Long Island City

PROCHAZKA, GUSTAV Z., Scientific Hull Draftsman, Newburgh Shipyards, Inc., Newburgh

SPENCE, PETER C., Mechanical Engineer, Department of Labor, State of New York, New York

TOURNIER, EDWARD J., Chief draftsman, American Ore Reclamation Co., New York

ULMANN, AUGUST, JR., Construction Engineer, Walter Kidde & Co., Inc., New York

WHITE, ELISHA J., General Superintendent, Standard Shipbuilding Corp., Port Richmond, Staten Island

WHITE, JAMES A., Chief Engineer, Harrison Radiator Corp., Lockport

WILLSEA, LOUIS P., President and Treasurer, The Willsea Works, Rochester

North Carolina

CHRISTIAN, CHARLES W., Manager Heating Department, General Fire Extinguisher Co., Charlotte

Ohio

ARTHUR, HARRY G., Machine Designer, Firestone Tire & Rubber Co., Akron

GATES, ROBERT M., Engineer, Thew Automatic Shovel Co., Lorain

HUNTER, JOHN R., Engineer Production, Goodyear Tire & Rubber Co., Akron

LOGEMAN, WILLIAM F., Superintendent The Standard Elec. Tool Co., Cincinnati

MAY, JOHN T. L., Instructor in Mechanical Engineering, Ohio State University, Columbus

YAEGER, HARRY C., Chief M. E., The Dalton Adding Machine Co., Norwood

Pennsylvania

EBERT, GEORGE W., Assistant Superintendent, Pedrick Tool & Machine Co., Philadelphia

LANDRY, JAMES N., Superintendent of Production, Aerial Bomb Div., Marlin-Rockwell Corp., Philadelphia

LEONARD, DAVID E., Chief Inspector, Remington Arms Co., Eddystone

MAGEE, WILLIAM G., Assistant Superintendent, The Baldwin Locomotive Works, Eddystone

MOSES, FRED C., Designing Engineer, Bethlehem Steel Co., Bethlehem

ROBERTSON, WALTER M., Special Representative, Vice-President and General Manager's Dept., Pressed Steel Car Co., Pittsburgh
YINGLING, JOHN C., in Assistant Charge Engineering Department, Iron City Products Co., Pittsburgh

Texas

CLYNE, CECIL B., Sales Engineer, Mine & Smelter Supply Co., El Paso
INGLESH, H. O., Chief Engineer, Southwestern Portland Cement Co., El Paso

Virginia

FULLER, Raymond C., Marine Draftsman, Newport News Shipbuilding & Dry Dock Co., Newport News
VESTAL, FRANK J., Test Engineer, E. I. Du Pont de Nemours & Co., Hopewell Works, City Point

Canada

WEEKS, WILLIAM C., University Club, Vancouver, B. C.

Holland

VAN DIJK, J. W., Manager, Lindeteves Stokvis, New York, India and Holland, Amsterdam

Philippine Islands

ROESLER, BERNHARD K., General Manager of George Whalen & Co., Manila

South America

ONSALDO, PEDOR, Engineer, Chief Director, Compania Industrial de Electricidad, Buenos Aires, Argentina

FOR CONSIDERATION AS ASSOCIATE OR ASSOCIATE-MEMBER

California

PORTER, JAMES W., Assistant to Superintendent, Cowell Portland Cement Co., Cowell

Connecticut

GRAHAM, GEORGE A., Engineer, Naugatuck Chemical Co., Naugatuck

WHATMORE, ALBERT, Chief Assistant Engineer, The Olympia Oil & Cake Co., Ltd., Selby

FOR CONSIDERATION AS ASSOCIATE-MEMBER OR JUNIOR

Connecticut

BRENNAN, MICHAEL J., Checker of Tool Design, Colts Patent Firearms Mfg. Co., Hartford
HENRICKSEN, HARRY E., Mechanical Engineer, American Graphophone Co., Bridgeport
WOOD, HAROLD J., Draftsman, Remington Arms-U. M. C. Co., Bridgeport

Illinois

CAMERON, WILLIAM E., Maintenance Engineer, Sherwin-Williams Co., Plant No. 2, Kensington
MORGAN, EVERETTE K., General Superintendent, Rockford Drilling Machine Co., Rockford

Massachusetts

SIBLEY, EDWARD W., Mechanical Engineer, Aberthaw Construction Co., Boston

Michigan

SPREEN, CHARLES C., Assistant to Assistant General Manager, Dort Motor Car Co., Flint

New Jersey

CRARY, JAMES H., Inspector of Machinery, Bureau of Steam Engineering, U. S. Navy, and Babcock & Wilcox Co., Bayonne
PERRY, JESSE V., Assistant Superintendent, Spencer Kellogg & Sons, Inc., Shadyside

New York

BRICE, NORMAN E., Mechanical Engineer, The Permutit Co., New York
GARLAND, PHILIP, Mechanical Engineer, Technical Department, The Permutit Co., New York
JONES, WALTER H., Engineering Draftsman, New York Central Railroad Co., New York
MITCHILL, GEORGE L., Chief Inspector, Electric Bond & Share Co., New York

Oklahoma

COLLINS, SAMUEL W., Oil-Drilling Contractor in Oil Fields of Okla., Tulsa
MULLERGREN, ARTHUR L., Secretary and Treasurer, Electrical and Mechanical Engineer, Benham Engineering Co., Oklahoma City

Pennsylvania

TAYMAN, GEORGE S., Mechanical Engineer and Draftsman, Crucible Steel Co., Pittsburgh

FOR CONSIDERATION AS JUNIOR

Connecticut

PAUGH, CHARLES T., Assistant Chief Draftsman, Small Tools Department, Remington Arms & Ammunition Co., Bridgeport

District of Columbia

BOYLES, RALPH R., Draftsman, Ordnance Department, U. S. Naval Gun Factory
FLAD, ALBERT E., Mechanical Draftsman, Engineering Bureau, Ordnance Department
FORD, ARTHUR C., Mechanical Draftsman, U. S. Ordnance, Engineering Bureau
PARKHURST, DOUGLAS L., Mechanical Draftsman, Ordnance Department, War Department

Illinois

MAITRA, KRISHNA M., Special Apprentice, Chicago & North Western Railway, Chicago

Maryland

ADDISON, WALTER W., Chief Draftsman and Assistant to Chief Engineer, Baltimore Tube Co., Inc., Baltimore
MOORE, JOHN H., Production Department, Bartlett Hayward & Co., Baltimore

Massachusetts

KENDALL, GEORGE H., Head of Standards Division, Engineering Department, Norton Co., Worcester
LEVI, ELIJAH, Ship Draftsman, Boston Navy Yard, Hull Division, Boston
WINDLE, ARTHUR E., Cadet in Ground Officers' Training School, Aviation Section, Signal Corps at Massachusetts Institute of Technology, Boston

Michigan

SMITH, JOHN M., Draftsman, The Prescott Co., Menominee

Minnesota

GUNNARSON, CARL A., Assistant Superintendent, Department of Buildings and Grounds, University of Minnesota, Minneapolis
PALMER, LLOYD J., Chief Clerk, Chief Engineer's Office, Northern States Power Co., St. Paul

Missouri

LUBKE, ARTHUR F., Consulting Engineer, St. Louis

New Jersey

GAISSERT, HERMAN O., Mechanical Engineer, Keuffel & Esser Co., Hoboken

New York

BEROLZHEIMER, HENRY, Student in Chemical Engineering, Columbia University, New York
HILL, ERNEST K., Machinist, Thomas Morse Aircraft Corp., Ithaca
PETERSEN, CARL E., Assistant to General Superintendent, Morse Dry Dock & Repair Co., Brooklyn
POLDERMANS, DANIEL, JR., Assistant Secretary and Treasurer, Wonham, Bates & Goode, Inc., New York

Ohio

REHN, OTTO F., Special Apprentice, Buckeye Steel Castings Co., Columbus
HAMILTON, HARRY E., Efficiency Foreman Coke Plant, The Youngstown Sheet & Tube Co., Youngstown

Oklahoma

HIGLEY, Frank R., 1st Lieutenant, Ordnance Department, Infantry School of Arms, Fort Sill

Pennsylvania

LEBAIR, MOREAU S., Assistant to Purchasing Agent, Central Construction & Supply Co., Philadelphia
MURDOCK, ALEXANDER, JR., Engineer, D. L. Taylor Co., Inc., League Island Navy Yard, Philadelphia
TIETZEL, ALBERT M., Designer Coke-Plant Work, Cambria Steel Co., Johnstown
WOLFF, JOHN F., Engineer, The Schwarz Wheel Co., Frankford, Philadelphia

Rhode Island

SMITH, NORMAN H., Draftsman, Potter & Johnston Machine Co., Pawtucket

Virginia

DE KLYN, JOHN, Technical Assistant, National Advisory Committee for Aeronautics, Hampton

Canada

STILES, EDWIN M., Chief Draftsman, Consolidated Mining & Smelting Co., Trail, B. C.

EMPLOYMENT BULLETIN

THE SECRETARY considers it a special obligation and pleasant duty to make the office of the Society the medium for assisting members to secure positions, by putting them in touch with special opportunities for which their training and experience qualify them, and for helping anyone desiring engineering services. The Society acts only as a clearing house in these matters.

IN forwarding applications, stamps should be enclosed for transmittal to advertisers; applications of non-members should be accompanied by a letter of reference or introduction from a member, such reference letter to be filed with the Society. Copy for The Journal should be in by the twelfth of the month.

GOVERNMENT REQUESTS

MEN WANTED AT ONCE for Government work in Division of Trade Tests as a Committee on Classification of Personnel in the Army to engage in preparation of data and questions and also outline possible performance tests to be used in carrying out the work in the possible trade ability of men in the camps and cantonments, or some of the work in the new draft. Must be men, if possible, broadly familiar with wide variety of industries and competent to formulate or assist in formulating questions to be used in these matters, correspondence with or visits to individuals or camps nearby, from whom they can obtain original data, or confirmation and testing of data which has been prepared, and otherwise in assisting in the preparation of this material. Subsequently to probably be located in the various camps and cantonments to cooperate with the Army Personnel Officers in the application of data which have been prepared and obtained. 2584.

DRAFTSMEN for Bureau of Ordnance, Navy Department. Graduates in mechanical engineering from a technical school or college of recognized standing and who have had some drafting experience, or men who are competent designers of heavy machinery, engines or shop tools and have had a number of years' drafting room experience. Pay ranges from $4 to $6.88 a day, depending upon the qualifications of the draftsmen. 2585.

MEN for Inspection Division Ordnance Department, with both technical training and shop experience and who are beyond the draft age; those accepted will be commissioned. Also men within draft age who have the required qualifications and are not in the first class will be considered for commissions. 2586.

ONE HUNDRED CANDIDATES for commissions in Ordnance Officers' Reserve Corps required for Trench Warfare Section of Ordnance Department. Men over draft age, physically sound, of good character, with business experience, university training and technical skill particularly needed. Application form will be forwarded by the Society. 2588.

POSITIONS AVAILABLE

SALESMAN, preferably experienced on conveying machinery. Splendid opening with good future for right man. Please give full details of experience, age, salary expected, etc. Location Missouri. Record and applications confidential. 1186-C.

THE WESTERN ELECTRIC CO. has opportunities for physicists, engineers, designers and draftsmen for work of research, development and design related to problems of telephonic, telegraphic and radio-communication, which are matters of public importance. Both temporary and permanent positions are open. Apply by letter, not in person to F. B. Jewett, Chief Engineer, 463 West St., New York City. 2178-C.

MECHANICAL ENGINEER, technical graduate, with several years' experience along general and mechanical lines. One conversant with industrial machine design preferred. Permanent position with large corporation. State age, college, previous experience and salary desired. Location Cleveland. 2023-C.

MECHANICAL DRAFTSMAN. Young college graduate preferred. General industrial mechanical engineering work. Permanent position with large corporation. State age, college, experience if any, and salary desired. Location Cleveland. 2024-C.

SALES MANAGER. Engineer experienced in estimating and selling to hold responsible position in long-established engineering and contracting business of an incorporated company. Possible opportunity to become financially interested. Give age and experience in reply. 017-C.

METALLURGIST of good training and reasonable experience for work along lines of heat treatment, experimentation, machine grinding, tube and steel production and gas producers. Location Ohio. 023-C.

DRAFTSMAN, experienced in flour-mill, grain elevator, power-transmission, elevating and conveying machinery. Location Kansas. 024-C.

DRAFTSMAN - DESIGNER on electrical machinery, etc. Salary $1500 to $1800. Location Bayonne, N. J. 026-C.

ENGINEER AND DRAFTSMAN on designing of marine machinery in a large and long-established corporation. Location near New York. 028-C.

GENERAL SUPERINTENDENT for plant near New York with over 1200 employees. Applicant must have a technical training, a highly developed technique in widely different fields, a keen sense of justice, obvious ability to be a successful executive in a democratic organization, and a thorough appreciation of the importance of making deductions from facts alone. The man chosen for the position will be given opportunity to learn technique and establish himself in the confidence and esteem of the personnel. He will probably not be given full responsibility within a year. Department is one of very large organization and affords opportunity for advancement. 032-C.

MECHANICAL ENGINEER AND MASTER MECHANIC. American preferred, 30 to 50 years of age, for factory employing about 500 people. Well-equipped machine shop for repairs and manufacture of new machinery. Really capable man wanted who has sufficient training and experience to qualify him for his work. Must be a technical graduate, with thorough practical experience; able to handle men; sober, reliable and ambitious. Suitable salary and good future assured to right man. Reply by letter, stating experience and qualifications. Location, N. J. 033-C.

YOUNG MECHANICAL ENGINEER with three or four years' practical experience out of college, for chemical testing of boilers, fans, pumps, etc. Salary depends on man. Apply by letter. Location New York, with occasional trips in the East. 039-C.

DRAFTSMAN for New York office. Man over 30 years of age who is capable of developing suggested ideas in machine tools. Willing to pay $40 per week or more to man of more than average ability. 040-C.

DRAFTSMEN AND DESIGNERS for routine copper- and brass-mill work. Several men who are qualified to accept such a position. Long experience in a copper or brass mill not absolutely essential, but a good mechanical knowledge is. Location Elizabeth, N. J. 042-C.

YOUNG ENGINEER capable of handling boiler tests to determine the most economical operation under various grades of coal and under different station loadings. Should be familiar with boilers, stokers, methods of testing and the working up of the tests. Location Poughkeepsie, N. Y. 044-C.

ELECTRICAL OR MECHANICAL ENGINEERING GRADUATE in works-engineering division. Prefer man with experience along lines of industrial power-house and electrical engineering. Location Connecticut. 045-C.

APPRAISAL ENGINEERS who have the experience and are competent to make appraisal of equipment and machinery for by-product coke-oven plants, chemical plants, bituminous coal mines, etc. Prefer to engage competent parties in Milwaukee or Chicago. 047-C.

YOUNG EFFICIENCY ENGINEER with practical experience in time study, rate setting, piece, premium and bonus systems, as assistant to head of department. Must be able to supervise. Excellent opportunity. Give age, education, previous experience, salary desired, etc. Reply Efficiency Department, P. O. Box 400, Cleveland, Ohio. 052-C.

HIGH-GRADE TECHNICAL SALES ENGINEERS with personality, and experienced in gasoline trucks. Men who are producers, have made big money and who are able to stand prosperity. Experience must cover gasoline truck sales. References must be without question. 054-C.

ASSISTANT TO SUPERINTENDENT of mechanical department, a portion of the time as draftsman. Must be a technical graduate engineer with at least five years' experience in an industrial plant, preferably a glass-manufacturing concern. One having some experience in handling men and who has been successful in getting results in general plant construction, upkeep and maintenance, and also construction and maintenance of machinery, power plants and glass-house furnaces. Location New York State. 056-C.

DRAFTSMAN experienced in glass-house or steel-furnace design and construction; must have several years' experience. Location New York State. 057-C.

DRAFTSMAN experienced in general industrial plant, machinery repair and upkeep. Location New York State. 058-C.

DRAFTSMAN with at least six months' experience in mechanical designing for department of experimental engineering. Must have original ideas and initiative. Salary to start $1200. Location Connecticut. 059-C.

DETROIT SALES REPRESENTATIVE. Capable engineer to handle steam-heating specialties in Michigan. Salary, commission and expenses. State experience fully. 060-C.

ENGINEER skilled in the design of small steam turbines to design an efficient steam turbine of less than 10 hp. Temporary position. Location Pennsylvania. 064-C.

CHIEF ENGINEER to run plant of 2400 boiler hp. situated in New Jersey. Must have had practical experience with Corliss engines, condensing and auxiliary apparatus and methods of securing economical boiler operation. Must be able to control help. Mechanical experience necessary, technical experience desirable. 065-C.

BOILER-ROOM EFFICIENCY MAN. Young man who has tact, a pleasing personality and the perseverance to get the desired results. Should have a general knowledge of power plants and their operation and, if possible, actual experience in the operation of a power plant. Salary commensurate with ability to produce results. Location Rhode Island. 066-C.

HIGH-GRADE MECHANICAL ENGINEERS of construction experience for work on powder and explosive plants for U. S. Government. Apply, stating age, nationality, experience, references and salary desired. Location Delaware. 067-C.

SALES ENGINEER, between 25 and 30, for condenser and cooling plants. State experience, salary expected, and give references. Location Pennsylvania. 072-C.

SALESMAN experienced in high-class Diesel or semi-Diesel fuel-oil engines. Unusual opportunity on a salary and commission basis in desirable territory, covering a superior line of engines. State age, education, experience, etc. Location Illinois. 073-C.

SALES ENGINEER, high-class man, experienced in sale of Diesel or semi-Diesel fuel-oil engines; man of strong personality, capable of organizing and superintending agencies. A very attractive opportunity. Give, in confidence, age, education and experience. Location Illinois. 074-C.

ASSISTANT AND FOLLOW-UP MAN on operation of shell shop. Should be systematic and painstaking and have a general knowledge of mechanical drawings to readily identify parts and keep account of work in the shop. Location New Jersey. 075-C.

GENERAL FOREMAN for factory employing 100 men. Must be competent executive and experienced in manufacture of three-jaw independent chucks. Location Chicago, Ill. 076-C.

MECHANICAL ENGINEER with executive ability, experienced as experimental engineer on woodworking machinery. Salary depends on man. Location Middle West. 077-C.

SUPERINTENDENT in machine shop employing about 100 men. Technically trained man who has had actual experience as superintendent of a machine shop. Product is hand elevating trucks for use in factory transportation. Location Massachusetts. 080-C.

TOOL DRAFTSMEN for engineering department of concern. Brooklyn. Pay to start is $35 a week, with promotion; 48 hours a week. 081-C.

DESIGNER experienced on hydraulic presses and pumps. State experience and past connections. Location Illinois. 082-C.

MECHANICAL DRAFTSMAN for permanent position. Working conditions and prospects good. Location Minnesota. 083-C.

TOOL DESIGNER. High-grade man experienced on heavy automatic screw-machine tools. Must be capable of standardizing tools and records. Write, giving full details as to experience, references and salary expected. 085-C.

SUPERINTENDENT for boiler shop combined with heavy tank and plate works, also making light tank work, stacks, breechings, etc. Desire man of executive ability, organizer and one who can handle foremen and men for highest efficiency. State experience and salary expected, also when available. Location Middle West. 086-C.

DRAFTSMAN who is an experienced designer of railway cars, to design draft gear, journal boxes, etc., and make engineering calculations relative to same. Rate of pay in accordance with the ability of the man and general rate prevailing for such services at the present time. Wanted for a permanent position. Location New York State. 087-C.

STAFF OF 100 BIG MEN wanted by large industrial plant in Alabama engaged in important Government work. Superintendents, assistants, foremen and chief operators are needed. Chemical, electrical, electrochemical, gas, liquid air, refrigerating and mechanical engineers, all with operating experience; college men with technical training, and familiar with cement, power, refrigerating, chemical, sugar-refining and electric plants; operators experienced on mining and milling machinery, crushers, conveyors, compressors, furnaces, kilns, ovens. Competent men will be trained in the processes, paid good salaries during instruction, and given an attractive contract as soon as qualified. State age, nationality and experience. 088-C.

MEN AVAILABLE

SUPERVISING FUEL-EFFICIENCY AND WATER-SOFTENING ENGINEER. Member, under 40, with technical education and 18 years' experience in the construction and operation of steam plants, the handling of all classes of men, the testing and chemical treatment of waters, and in the burning and testing of gas, oil and all grades of anthracite and bituminous coals. Knows how to obtain results. Position must carry full authority and pay not less than $4000. C-54.

CHIEF ENGINEER OR MASTER MECHANIC with thorough technical and practical experience covering construction, operation and upkeep of steel plant. Specialty metallurgical work, heating and melting furnaces. C-55.

SAFETY ENGINEER with six years' thorough technical and practical experience in this capacity with large steel works in Pennsylvania. C-56.

ELECTRICAL ENGINEERING GRADUATE with five years' mechanical experience in design of oil-well tools and machinery including gas engines, compressors, pumping jacks, etc.; also experienced in design of machinery for manufacturing 6-in. shells. Student of Alexander Hamilton Institute. Prefers Government work, but will consider anything paying over $125 per month. C-57.

EXECUTIVE MANAGER. An executive of ability and aggressiveness, a mechanical, technical graduate, at present employed, desires to connect with a manufacturer whose business may need systematizing and building up as to organization and production. Has had a varied experience in different branches of manufacturing, operating industrial plants along lines of scientific management, and is fully conversant with modern methods of manufacturing and marketing products. Only interested in a permanent position offering good possibilities for improvement. C-58.

MECHANICAL ENGINEER, Member, technical graduate with over 20 years' shop and mill experience wishes to locate with large New England concern in executive capacity. An important opening only considered. Now employed. C-59.

MECHANICAL ENGINEER experienced in the design of power plants, industrial plants, heating, ventilating, etc. Has held executive positions and had charge of men. Desires responsible position. C-60.

AVAILABLE FOR GOVERNMENT SERVICE MARCH 1—INDUSTRIAL AND PRODUCTION ENGINEER with 17 years' manufacturing experience in metal-working trades. At present chief of production at plant employing 2600. Practical man, with exceptional experience, who desires to enter Government service. C-61.

STEAM ENGINEER wants position with large power or industrial company; six years' technical training in electrical and mechanical engineering, five years' experience in steam power work; familiar with all types of steam and electrical equipment. Associate member, A. S. M. E. Can furnish the best references. Will be available March 1. C-62.

MECHANICAL-ELECTRICAL ENGINEER, Columbia graduate, at present employed as manager of a very large concern, desires position as sales manager or superintendent. Experienced in internal-combustion engines and foundry and machine-shop practice, gas producers, power installations and marine power plants. Unusual business and technical training. Fully conversant with French, Italian and Spanish. Minimum salary to start $4000. C-63.

MECHANICAL-ELECTRICAL ENGINEER, Cornell graduate, age 32, married, desires executive position in the production or manufacturing department of a progressive concern where initiative and tact, coupled with past training and experience, will be of maximum value toward further advancement; experienced in machine-tool operation, design of labor-saving devices and special and automatic metal-working machinery; systematizing, production engineering, etc.; first-class references as to character and ability. Available on two weeks' notice. C-64.

INSTRUCTOR OR ASSISTANT PROFESSOR OF MECHANICAL ENGINEERING. Technical graduate with shop, drafting-room and teaching experience; can also handle military instruction. Services available at end of present semester. Location preferred Eastern or Middle Western States. C-65.

MANUFACTURING ENGINEER, 33, married, desires permanent responsible position. Thorough, mechanical and efficient production experience with fine machines and sheet metal goods. Present duties deal with labor-saving devices, estimates, investigations, rate and bonus layouts, instructions, etc. Salary $2500. C-66.

MECHANICAL OR WORKS ENGINEER. Technical graduate, age 30, married. Good organizer and executive, experienced in design, construction and maintenance of paper mills and metal-manufacturing plants, etc.; in management of shop, yard, office and drafting room forces. Location Eastern States preferred. C-67.

POWER PLANT ENGINEER with 26 years' experience. Can build and operate. C-68.

MECHANICAL ENGINEER AND SUPERINTENDENT. American, with 14 years' practical and theoretical experience. Specialist in steam, air, gas, oil and water engineering specialties; machine-tools, fixtures and shop equipment; shop maintenance, efficiency, engineering testing and production engineering. Executive who can go into shop and do things. Successfully held positions involving above. At present employed. Salary $3000. C-69.

MECHANICAL ENGINEER desires executive position in organization where small or medium-sized work is manufactured. Fourteen years' practical experience as tool and die maker, tool and automatic-machine designer and chief designer. At present assistant works manager in one of the best tool-manufacturing concerns in the country. Present salary $2500 plus bonus. C-70.

MECHANICAL ENGINEER OR ENGINEER OF CONSTRUCTION. Junior member, age 27, University of Pennsylvania graduate, married, class 4-A Federal draft. Engaged in gas, by-product coke, benzol recovery and power plants, erection and operation. Desires permanent position with growing concern where merit is appreciated. At present employed. Best of references. Salary to start $175. C-71.

CHIEF DRAFTSMAN OR PRODUCTION ENGINEER. Eleven years' experience in general engineering, charge of design of internal-combustion engines, railway cars and equipment, furnaces, plant layouts, installation of machinery, automatic machinery, jigs and tools, production, efficiency and routing. At present in charge of technical and mechanical problems in consulting capacity. Position must be permanent. Location New York City or vicinity. Salary $2200 to $2500. C-72.

INSTRUCTOR OR ASSISTANT PROFESSOR OF INDUSTRIAL ENGINEERING. Junior member, age 26, married, M. E. from prominent Eastern university, is looking for a change where he will have charge of the shopwork and teach subjects in industrial engineering. Has had general mechanical experience and since graduation studied and worked under a pioneer in the teaching of scientific management. For three years has taught shopwork under applied methods of shop management, had charge of the machine shop and taught time study, cost accounting, etc. Would assume new duties about September 1, but is desirous of starting correspondence now with those interested. Prefers to locate in the East. Minimum salary $1600. C-73.

ASSISTANT TO EXECUTIVE OR EXPERIMENTAL ENGINEER. Stevens M. E. graduate, 28, married, finishing present engagement some time in March. Three years' successful experience in executive and experimental work in natural gas, two years in power-plant operation. Possesses energy, initiative, self-confidence and unusual mathematical ability. Desirous of securing a position with large industrial or engineering concern. Position must be permanent and offer a future. Initial salary not a primary consideration. C-74.

DESIGNING ENGINEER, CHIEF DRAFTSMAN OR MECHANICAL EXECUTIVE, age 36, technically qualified; practical and supervising experience and competent to design, develop and standardize mechanical products, particularly machines involving complex mechanism and covering a range of sizes, or to organize or direct a department for such work. Specialized knowledge of design and production of a leading line of high-grade textile machinery and accessories, also valuable experience on steam and hydraulic appliances. Prefers connection with growing concern whose expansion calls for establishment of mechanical-development department, handling problems of product and equipment. Salary $3500. C-75.

EXECUTIVE OR ASSISTANT SUPERINTENDENT, American, technically educated, age 36. Practical mechanic, familiar with design of special machinery, tool, jigs, fixtures, etc., for manufacturing duplicate parts on interchangeable system. Twelve years in drafting room, part of time as chief draftsman; six years' shop experience, one as foreman. Salary $2500. Location preferred Eastern States. C-76.

MECHANICAL ENGINEER, Associate-member, age 34, with 12 years of broad experience in designing and construction of various automatic and special machinery. Practical man with executive ability and thoroughly versed in modern methods of interchangeable manufacturing. At present connected with a large corporation, but desires permanent position with prospects for future advancement. Salary $3000. C-77.

MECHANICAL AND MARINE ENGINEER, age 40, with 15 years' experience in the design and construction of ships and power equipment, engines, boilers and auxiliaries; also experienced along general engineering lines and electricity. Thoroughly competent to handle men and take charge of the design and construction of merchant ships and machinery. Good reasons for wanting to make change. C-78.

MECHANICAL ENGINEER with 10 years' experience in building and tool valuations and field engineering along the lines of mill and power buildings. Now open for engagement. Location Chicago or vicinity. C-79.

SALES ENGINEER. Member, age 34, experienced in the manufacture and selling of iron and steel, wishes position with high-class firm as production or sales engineer. At present employed. C-80.

PLANT ENGINEER. Member, age 39, with 12 years' experience in plant upkeep, designing new buildings and equipment, labor-saving and material-handling devices, repairs to machinery or equipment, power, light, heat and plumbing. At present and for past five years with large metal-working plant. Record of experience and references to those interested. C-81.

TECHNICAL GRADUATE (1904), member A.S.M.E., now employed as mechanical engineer and managing two steam-turbine plants, desires executive position with large manufacturer or public-utility company. Experienced in design, construction and maintenance of high-tension sub-stations, steam plants, piping, buildings, steam and electrical equipments. Best references. Locality Eastern States preferred. C-82.

ENGINEERING SURVEY

A Review of Engineering Progress and Attainment in Mechanical Engineering and Related Fields, Including a Digest of Current Technical Periodicals and Selected Titles of Engineering Articles

Saving Fuel Through Operating Economies in Electric Street Railways

THE Electric Railway War Board has recently made public the report made last December by a committee appointed to investigate the fuel savings possible on the street railways in Washington, D. C.

The report covers partly conditions peculiar to the city of Washington, but also touches upon subjects of general interest to electric street railways.

The report shows that the present system of car stopping at every corner (in some cases because of local regulations, even when there are no passengers to take on or discharge) involves a considerable delay in the operation of the cars and a material increase in the consumption of the coal. The committee recommends, therefore, the use of the skid-stop plan, or stopping at alternate corners, as well as the elimination of stopping at rapid-transit corners and other minor delays in operation.

Another recommendation covers the elimination of the present system of running an unnecessary number of cars to the far end of lines where there is not enough traffic. It is believed that for the Washington railways the elimination of unnecessary mileage would save approximately 3200 tons of coal per year.

Still another recommendation covers the generation of the entire power load for the two lines operating in the city at the most efficient plant of one of these companies. It has been found that because of various existing conditions one plant is able to operate with 1.9 lb. of coal per kw-hr., while the other two plants consume 2.6 lb. and 4.1 lb., respectively. Making suitable allowance for losses in transmission, the saving in coal from shutting down these two latter plants is estimated at 9700 tons per year.

A suggestion which might apply to a good many cities besides Washington, of course with proper modifications to meet local conditions, refers to staggering office hours of Government employees. It seems that there are nearly 50,000 Government-department employees who are dismissed each day at 4.30 p.m. This requires a material increase in the number of cars after 4 p.m., which can in a general way be attributed to the necessity for carrying department employees. Most of these additional cars, it is to be noted, make only two round trips.

If the office hours were staggered so as to begin at 15-min. intervals from 8.30 a.m. to 9.15 a.m. and to close correspondingly from 4.00 p.m. to 4.45 p.m., considerable relief would be obtained in street congestion and a saving effected in coal. It is estimated that on such a basis the rush-hour cars could make three trips instead of two, which would cut down the number of additional cars required for this purpose by a third.

It is interesting to note that while the total consumption of coal on the Washington street railways amounted to about 12,760 tons per month, the recommended savings would reduce this consumption by 25,790 tons per year. (*Electric Railway Journal*, vol. 51, no. 6, February 9, 1918, pp. 267-270)

Reorganization of the Quartermaster General's Office

Reorganization of the staff of the Quartermaster General was completed by Gen. George W. Goethals, Honorary Member Am.Soc.M.E., on January 26, and in addition to a general rearrangement of the administrative boards, it includes the storage and traffic service for the general staff.

In the general scheme of the new organization there are three service bureaus, but the Storage and Traffic Organization, comprising four operative divisions, is largest by an additional bureau called the Distribution Priorities Bureau. The function of this service will be to advise the Director of Storage and Traffic with respect to all matters of priority and distribution and to secure data on which to base the apportionment of the use of storage, transportation and embarkation facilities among the various operating divisions.

The three other bureaus embodied in the new organization are as follows:

The General Administrative Bureau has control of the preparation of data and orders for executive action, verification and approval of estimates and supervision of general administrative procedure in the various offices of the Quartermaster's Corps. It also includes an Information and Statistics Section and a Contract Supervision Section.

The second bureau is the Quartermaster's Supply Control Bureau, which comprises a Requirement Branch, a Distribution Branch (for both domestic and overseas troops), and an Administrative Branch.

The third is the Professional and Planning Staff, which supervises and orders all matters relating to office service, administrative methods, operating methods, industrial research, industrial relations and kindred matters for several operating bureaus.

In the reorganization of the immediate staff of the Quartermaster General several operating divisions have been created, each having its own Procurement Branch and Production Branch.

The above information is taken from the *Engineering News-Record* of Feb. 7, 1918, vol. 80, no. 6, pp. 248-250. The article has two charts, of which the second gives the personnel of the chief division of the Quartermaster's Corps.

U. S. Plans to Use Surplus Northwest Water Power in War

The Government is preparing to use the surplus water power of the Northwest for war industries.

A survey will be the first step. It was ordered last December by the power committee of the Council of National Defense. C. O. Frisbie, of Chicago, president of the Wood Products Co. at Cornell, Wis., and head of the Chippewa Valley Operative Association, was selected for the task, and will begin at once.

The power committee has asked for the following information:

How much power is developed from Government and private dams in Minnesota and Wisconsin?

How much additional power can be obtained by improvement of the present facilities?

How much surplus over the present needs of industries and municipalities can be produced?

How much can the present users of power curtail their consumption?

How much of their supply will present users be willing to divert for Government purposes?

It is believed that the survey will disclose thousands of horsepower readily convertible to industrial users. Chippewa Falls and International Falls are the two points from which most is expected, but a close study will be made of the entire field.

The hope is to obtain coöperation of local industries and municipalities in getting much needed power for new war plants. Failing in this, the Government will not hesitate to commandeer the output, as was done at Niagara Falls last week by President Wilson.

The coal shortage makes it imperative the Government turn more to the use of water power. New factories, especially chemical plants, must be built, and the only hope of operating these at capacity and meeting the other fuel needs of the country is to utilize natural power.

Until Mr. Frisbie has completed his work and made his recommendations to the power committee there will probably be no decision in the disposal of surplus power from the high dam at the Twin Cities. (Minneapolis *Morning Tribune*, December 31, 1917, p. 1)

New Gun Plant of the Tacony Ordnance Corporation

The Tacony Ordnance Corporation is rapidly completing extensive and modern facilities for the production of large-caliber, rough-machined gun forgings. The plant, which will cover approximately 22 acres at Tacony, Philadelphia, will be completed about March 1, 1918. Present plans call for the following buildings: open-hearth and stock yard, forge, heat-treatment, machine-shop, chemical, physical and microscopic laboratory, storehouse, dispensary and administration building.

The open-hearth, which will have a capacity of from 700 to 800 tons of ordnance ingots per week, will operate two 40-ton acid, oil-burning furnaces, with 3½-ton charging machine, cranes, oil-storage tanks, etc. A 2000-ton and a 1000-ton steam-hydraulic forging press, with heating furnaces, etc., will furnish ample forging capacity. In the heat-treatment department there will be three vertical quenching and three car-bottom furnaces with necessary pyrometric control and dipping cranes. The machine shop will house about 50 machine tools, including a number of 48-in. and 36-in. turning and boring lathes, shapers, planers, etc. A small but complete toolroom will be maintained.

The new plant will be devoted exclusively to the production of rough machine forgings for howitzers and guns for the United States Army. About 500 to 600 employees will be required to operate the plant at capacity. J. B. Warren, secretary and manager of the Tacony Steel Co., is president of the Tacony Ordnance Corporation, and George Satterthwaite, formerly general superintendent of the Midvale Steel Co., is vice-president and general manager. (*The Iron Age*, vol. 101, no. 2, January 10, 1918, p. 175)

Softened and Asphalted Paper for Wrapping

A practical substitute for burlap to be used for baling and wrapping purposes was recently put on the market by the Cleveland-Akron Bag Company, Cleveland. Burlap substitutes are now of interest, as available supplies of burlap have had to be diverted for use to such purposes only as cannot be filled by other materials.

Machinery and machinery parts, electric motors and dynamos are wrapped for shipping in burlap; for coils of wire and auto tires narrow strips of burlap are used. Burlap is put to hundreds of such purposes which can, and to save burlap for more essential uses should, be performed by other practical substitutes.

The new substitute, "Saxolin," is made of two pieces of heavy paper combined with an asphalt material, making a waterproof combination. In the manufacturing of this product it is softened and made pliable so that the folding qualities of the paper are retained.

In tensile strength it is said to test equal to burlap used for a like purpose. There are four different weights corresponding to different grades and weights of burlap.

"Saxolin" cannot fill all the purposes of burlap, but in the range that it can supply, it will aid to place the available supply of burlap in the channels most needed. (*Journal of Commerce*, January 3, 1918, p. 17)

Pulverized Coal for Central Railroad of Brazil

The Central Railroad of Brazil recently inaugurated a series of experiments with its new coal-pulverizing plant at Barra do Pirahy, which caused considerable interest and favorable comment in engineering circles, according to the *Commerce Reports*. The plant was furnished by an American firm and installed by one of its engineers. The pulverizer is described as being similar in construction to a cement plant. The coal, freed of its moisture, goes into a hopper and is pulverized so that 80 per cent of it can pass through a 200-mesh screen. It is then passed to the locomotive by means of a conveyor screw and blast, thus bringing the ignitable powder to the mouth of the locomotive furnace, at which point combustion takes place. The first set of experiments were with American coal and were an unqualified success. The experiments were then continued with a mixture and finally with Brazilian coal from the Jacuhy district, until now somewhat problematically useful—"problematically useful" because it is a coal that does not burn economically in the usual lump form. It was, however, believed that, once pulverized, this coal would give good results and would prove to be adaptable to the needs of the railroads. The experiment, as reported, was an unqualified success and was hailed as an auspicious event that represents the solution of one of the most vital national problems in Brazil. (*Power*, vol. 46, no. 24, December 11, 1917, p. 793)

French Method of Tinning Cast-Iron Vessels

A method for tinning cast-iron pots and other utensils for domestic use is offered from a French source, *La Chronique Industrielle*. For household utensils only pure tin should be employed and not tin and lead, as the latter forms poisonous salts with the acids of food products. To insure adhesion of the tin the iron should be treated to remove the carbon, or otherwise it should be polished by mechanical means To remove the carbon, the iron is coated with a layer or oxide of iron or manganese, or else the iron is enclosed in a box with

the oxide and maintained at a high temperature to burn out the carbon. After four to six hours the iron is sufficiently decarbonized to permit the adhesion of the tin. After this procedure the iron is cleaned with dilute sulphuric acid to which is added a small amount of blue vitriol. The iron is then immersed in molten tin, or, if the interior of the vessel is to be coated, molten tin with a little sal ammoniac is vigorously rubbed over the surface. It is preferable to heat the iron before applying the tin. This must be done with care, otherwise the surface will be oxidized and impair the adhesion of the tin (*Mechanical World*, vol. 62, no. 1616, December 21, 1917, p. 337)

Society of Automotive Engineers

At the monthly meeting of the Minneapolis Section held in connection with the Twin City Automobile Show the important problem of burning kerosene in tractor engines was discussed. Professor Mowry of the State Agricultural College took the stand that the increased use of kerosene and heavier fuels is more dependent on engine designers than on carburetor or manifold makers. He quoted figures from tests made at his university on kerosene fuel with hot-spot manifolds. The tests were made with a four-cylinder L-head engine with a removable head and the duration of the test was 1 hr. Water temperatures ranged from 190 to 212 deg.

The tests were made with several types of manifolds and vaporizers and the dilution of the crankcase oil due to the admixture of kerosene in the crankcase varied from 0.1 to 0.7 lb. In some manifold tests it was even impossible to run the engine the full hour, because after about half an hour it stopped through preignition.

W. G. Clark, engineer of the Wilcox, Bennett Carburetor Company, who has just returned from a three months' investigation trip among tractor farmers from Texas to Montana, declared that the situation so far as burning kerosene in tractors is concerned is very serious, due to tractor makers selling tractors that are supposed to burn kerosene satisfactorily, but which fail to do it in the service of the farmers. He claimed that the hot-spot manifold is not a solution of the kerosene problem, because it increases the temperature of the mixture too much and cuts down the volumetric efficiency of the engine so that from a quarter to three-tenths of the engine power is lost.

E. R. Greer, engineer of the Emerson-Brantingham Company, expressed the opinion that the hot-spot manifold to accomplish its object must have some form of heat control. Consideration must be given to the speed of travel of the mixture in the manifold as well as the temperature of the manifold. When there are high gas speeds with open throttle, less heat is needed, but when the throttle is closed, heat must be added to prevent loading up. (Based on the report published in *Automotive Industries*, vol. 38, no. 7, February 14, 1918, p. 380.)

Hydroelectric Development

At the meeting of a special committee of the United States Chamber of Commerce on January 14, 1918, a statement was submitted on behalf of the Engineering Council by Calvert Townley, touching upon the subject of hydroelectric development generally and as a means of replacing steam power plants.

There are two fundamental causes which have militated against the substitution of hydroelectric for steam-electric power. One is economic and permanent, the other is statutory and therefore subject to modification.

The economic reason is the high cost of development due to natural conditions. Hydroelectric plants usually carry much heavier fixed charges than steam-electric plants, partly because in a water development a large share of the initial cost is consumed by expenditures for riparian rights, the dam and other hydraulic installations, transmission, right of way, towers, etc. A further share of the greater first cost of hydroelectric plants is due to the fact that, unlike the steam plant, the hydroelectric plant at the start must largely be built with a view to the future and not the actual market, and therefore for years has to carry excessive overhead. As a result, the projectors of the hydroelectric enterprise must often rely for success on a subsequent increase in their market, and the possibility of an incorrect forecast of the extent of such increase and of the time when it may come, imposes a serious business hazard against water and in favor of steam.

Another element in favor of steam is, that with the growing advancement of the art, both the first cost of machinery per unit of power and the cost of operation in the case of steam prime movers tend to decrease, and there is nothing to indicate that the limit of improvement in the design of steam prime movers has been reached or is even in sight. Further, where fuel oil is available, the Diesel or internal-combustion engine is also coming forward as a competitor of water power.

In fact, many sites which fifteen years ago might have been developed to sell energy in successful competition with steam at its then cost, could not now be so developed. On a concrete example, the report shows that the cost of fuel per unit of installed capacity in a steam-electric plant of average good design may be taken at \$11.50 per year. Under the usual conditions this would mean that a hydroelectric plant would be superior to or at least equal to this steam plant provided the hydroelectric investment per kilowatt capacity exceeded that of the steam plant by not more than \$100. As a matter of fact, many hydroelectric developments exceed this limit considerably, in which case they can be commercially successful only if either they are located in sections where coal is more than normally high, or are operating under more than usually favorable conditions, for example, with a plant factor in excess of the usual 35 per cent.

The conclusion which the report emphasizes is that while under certain conditions water power may commercially compete with steam, the view that it can under all conditions produce power at the lower cost than steam is quite a mistaken one.

The report proceeds to discuss certain legal obstacles in the way of water-power development in the United States, and shows, for example, that the discretionary right given to the Secretary of the Interior to revoke permits for the use of public land necessary for water-power developments, operates against the flow of private capital into such projects.

While the Engineering Council does not consider itself as expert in legal matters, the report points out that after a hydroelectric enterprise has been successfully established it is to everybody's interest that it should continue without interruption and all legal obstacles in the way of its operation should be as far as possible eliminated.

The report further expresses the belief that the benefits afforded the communities served by cheap power and the nation by the conservation of coal are far more valuable than the question of restricting returns to capital. The present emergency has shown how important the substitution of water power for steam power might be in releasing to other uses

the extensive transportation facilities now engaged in carrying coal as well as the corresponding volume of labor now occupied in mining this coal, and in converting it into motive power.

Engineers Control War Industries

Germany had prepared for a six months' war. Her supplies, her armies, her transportation system were all tuned for this period. For the general staff had figured the campaign with such precision that any greater extension of preparation would be a waste of national effort. Only one man in the empire felt that the chance of plans miscarrying was of sufficient importance to provide against. This man, an engineer high in the counsel of the Allgemeine Elektricitäts Gesellschaft, felt that to enter into a project as subject to failure as a military campaign, without a plan whereby every resource of the nation might be concentrated on the effort, was suicidal. But he had to wait for the stalemate of December to obtain the opportunity of putting the whole of the industrial resources of the country on a planning and progress chart basis.

This sidelight on the military situation in Europe at the beginning of 1915 is neither invention nor rumor. It is fact, well vouched for by men of undoubted reliability. Therefore, it should be welcome news to the engineers of America to know that a start in the proper direction has already been made in this country. The Office of the Chief of Ordnance has had for some time a planning division in certain of its own shops, and is now extending this most important work to all the factories making supplies for the office. The Progress Section of the Control Bureau, functioning as a division of the Ordnance office, keeps its mind on the progress of all war orders within its jurisdiction. Under Major Sanford E. Thompson, Mem. Am. Soc.M.E., a corps of men keep in touch with the promises and performances of manufacturers, determine wherein lies the cause of delays and what steps must be taken to keep production up to the schedule of requirements which have been determined as necessary to our full and successful participation in the war.—*Engineering News-Record*, February 14, 1918.

This Month's Abstracts

Special attention is called to a remarkable investigation on measurement of torsional stresses abstracted in the section Mechanics.

As yet we have no means of measuring torsional stresses directly. In members of very simple cross section, for example, circular, we can determine the torsion mathematically with considerable precision, but this is not feasible in the case of members of complicated cross-section, such as, for example, aeroplane struts. Nevertheless, this is a case where measurement of torsion is especially important, as aeroplane members must be both of ample strength to meet possible peak loads, and also of minimum weight—two conditions which require considerable knowledge of the properties of materials used and stresses to which these materials are subjected.

Griffith and Taylor have solved this problem by the so-called soap-film method described in the abstract. It is of interest to note in this connection that the properties of soap films and soap bubbles have recently been investigated in several respects, and there is gradually being built up what one might perhaps call "soap-bubble engineering," in the better sense of the term.

The Pittsburgh Testing Laboratory, Pittsburgh, Pa., is now engaged on a five-year test of coarse aggregates in concrete. The results obtained in the first six months are reported in the section Engineering Materials.

In the same section will be found a discussion of the different rates of loading as affecting the compressive strength of concrete.

In the section Hydraulic Engineering is described the equipment of the White River plant, containing two very large Francis turbines operating under a net head of 440 ft. The most interesting feature of this installation is its system of regulation and protection.

The section Internal-Combustion Engineering contains descriptions of several interesting devices.

The Chapman Engineering Company has developed a gas producer with a floating agitator, so arranged as to continuously stir up the entire surface of the fire bed in the producer.

From an English publication is reproduced a discussion of the time required for exhaust pressure in a two-stroke-cycle engine to fall from its initial value to the atmospheric level. A formula is given which makes it possible to determine the position of the piston for any crank angle.

In an abstract published in THE JOURNAL in January 1914 were described the general features of the Kromhout oil engine. In the present issue a unit is described developing as high as 350 hp. and having some interesting features of governing.

G. E. Stoltz, in an abstract in the section Mechanics, discusses the design of flywheels for rolling mills and shows how a comparatively small flywheel properly located may increase the monthly output of a mill by approximately 10 per cent.

The automatic control and measurement of high temperatures is exhaustively discussed by Richard P. Brown in a paper before the Steel Treating Research Society. Among other things are described instruments for the various temperature measurements and automatic temperature control.

In the section Munitions, particular attention is called to the bibliography on gages and gage making for munition plants, prepared by the Library of the United Engineering Societies. No attempt has been made at making an exhaustive bibliography, the aim being mainly to give a list of papers and articles of particular value to American manufacturers.

A new system of locomotive feedwater heating is described in the section Railroad Engineering. One interesting feature of the heater consists of the agitators contained in each of the tubes, so arranged as to bring each particle of water in contact with the hot tubes and to absorb all the heat possible from the exhaust steam on the outside of the tubes. It appears that the higher the velocity of the cold water passing through the tubes, the more violent the agitation and the greater the amount of heat absorbed by the water.

From British publications an abstract is made of a report submitted to the North-East Coast Institution of Engineers and Shipbuilders on various methods of producing high vacuum.

Soon after the beginning of the war various conditions combined in preventing copies of German technical periodicals from reaching this country. In particular, copies of the *Journal of the German Society of Engineers* ceased to come about the middle of 1915. Arrangements are now being made to secure the back issues, and there is good reason to believe that the Society will have them ere long. In that case some arrangement will be made to make the valuable information contained therein available to the membership of the Society.

REVIEW OF ENGINEERING PERIODICALS

Acoustics

The Doppler Effect, A. E. Watson and G. H. Makey. *Flight*, No. 469 (no. 51, vol. 9), December 20, 1917, pp 1335-1338, 4 figs. Discussion of the Doppler effect and its application to the location of flying machines in the air. According to the Doppler principle, the pitch of a note as heard differs from the true pitch of the note as emitted by the source of the sound in accordance with one or both of the factors, namely, relative movement between the source and the medium of oscillations, and relative movement between the observer and the medium. In the present article is examined only the case in which there is relative movement between the source and the medium. This applies particularly to the case of the observer being stationary in the air or on the ground while the note is coming from an aeroplane moving through the air.

Engineering Materials

Tests of Slag Concrete. A series of tests for the purpose of comparing slag, gravel and stone as the coarse aggregates for concrete is being carried on by the Pittsburgh Testing Laboratory, Pittsburgh, Pa., it being the intention to extend the tests over a period of five years. The tests made up to the end of the first six months have now been made public.

The fine aggregate is sand from the Ohio River, while the coarse aggregates cover nine varieties of slag gathered from plants in various parts of the country, two kinds of gravel, two kinds of limestone, a trap rock and a crushed granite. The proportions were determined by establishing the leanest mixture which would produce a dense concrete when using the coarse aggregate having the highest percentage of voids and then using the mixture for all the materials. This led to the use of proportions of one part cement, two parts sand and four parts of the coarse aggregate. The specimens were kept in molds for 48 hr. and were then stored in damp sand for 35 days, after which followed storage in air. Four short pieces of reinforcing steel were imbedded in each of two cylinders from every batch for the determination of the corrosive tendencies. The results shown in Table 1 were obtained. (*Railway Age*, vol. 64, no. 3, January 18, 1918, pp. 165-166, *e*)

Fire Tests of Building Columns, Noeman F. Kimball. *The Armour Engineer*, vol. 10, no. 2, January 1918, pp. 107-116, 2 figs. Description of tests carried out at the Underwriters Laboratories in Chicago for the purpose of determining the ultimate fire resistance of large building columns and the fire-resistive value of various kinds of column protection. No actual results of the tests are reported.

[illegible] CEMENT [illegible] PLASTICS. *Engineering*, vol. [illegible], January 18, 1918, pp. 71-73. To be continued.

[illegible] APPLICATION OF LOAD ON COMPRESSIVE STRENGTH [illegible], D. A. Abrams. A discussion of the different [illegible] loading as affecting the results obtained from pre[illegible] of concrete.

[illegible] the conclusions at which the writer arrives is that for [illegible] mixes (1:5 and 1:3) tested at the age of 28 days, the strength when loaded at 0.15 in. per min. is 14 to 20 per cent higher than when loaded at 0.006 in. per min.

If part of the load is applied at a fast speed and the remainder at a slow speed, the ultimate strength of the concrete is not changed, even though as much as 88 per cent of the total load is applied at the fast speed.

Knowing the approximate strength of the specimen, it will greatly expedite the work of testing and involve no sacrifice in accuracy, if we apply, say, 50 to 75 per cent of the ultimate load at a fast speed before changing to the slow speed.

A machine speed which gives a shortening of the test piece of 0.01 to 0.02 in. per min. per ft. of the length is recommended as a standard rate for compression tests of concrete.

The results show that the mean error of a group of tests

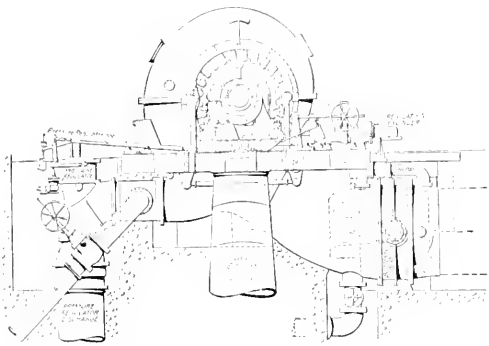

FIG. 1 25,000-HP. FRANCIS TURBINE

made on the same day is considerably lower than that of a set of tests made on different days; while the mean error of the daily average compressive strengths is generally much higher than that of the average tests made on different days. (*Engineering and Cement World*, vol. 12, no. 2, January 15, 1918, pp. 33-36, 2 figs., 4 tables)

GERMAN-MADE BOILER TUBES. When the former German liner *President Grant*, now *U. S. S. President Grant*, was being put through preliminary tests after the necessary repairs, it was found that her boiler tubes were defective. Samples of the tubes taken out were tested at the New York Navy Yard by Prof. William Campbell, who, by the way, did not know where the tubes were obtained.

Standard tests and microphotographs were made, and it was found that the German tubes were even poorer than such American tubes as have been previously rejected by the Navy. Mottling was found, presumably due to segregation of phosphorus, as well as abnormally coarse grain. Phosphorus contents of 0.263 were found, while the sulphur was about the same as in American tubes, or 0.018. Excessive brittleness was also discovered. (*Iron Trade Review*, vol. 62, no. 4, January 24, 1918, p. 271, *e*)

Hydraulic Engineering

LARGEST HIGH-HEAD FRANCIS TURBINE, Arnold Pfau, Mem. Am.Soc.M.E. Description of the hydroelectric equipment installed in the White River plant of the Puget Sound Traction Light and Power Company near Sumner, Washington. This plant contains two 18,000-hp. Francis turbines operating under a net head of 440 ft., which have developed over 44,000 hp. without any detriment to their efficiency.

In order to prevent excessive variations in speed and voltage of the power system it was necessary to use a very sensitive governor to quickly control the gates of the turbine. The sudden change in the flow of water through the pipe lines and tunnel would cause pressure variations which would not only impair the regulation, but might accelerate to such an extent as to wreck the whole plant.

The following methods of precaution are used:

1 A surge receiver at the end of the tunnel for the purpose of preventing surges set up by the tunnel from materially affecting the pressure in the pipe lines and vice versa.

2 Pressure regulators so combined with the turbines that they permit of a sudden release of the water, which is brought to a stop when the governor closes the gates of the turbines quickly.

3 Air-cushioned tanks which supply hydraulic energy to the turbines when the demand of load is so sudden that the water cannot accelerate in the pipe line sufficiently fast to prevent a serious drop in pressure.

The proper combination of these devices, together with a liberal flywheel effect of the revolving parts of the generators, is said to have made it possible to attain a high accuracy of speed regulation.

The pressure regulator details are shown in Fig. 1. The regulator is directly connected to a branch pipe provided on the lower portion of the spiral casing. It consists of an elbow

with the circular disk valve opening and discharging water downwardly through the plain steel pipe into the tail race. The disk valve is connected to a piston subjected to water pressure controlled by a regulating valve, which in turn is relay operated from a direct connection to the turbine gates. The oil dashpot is so inserted into this connection that the motion of the turbine gates is transmitted to the regulating valve only when the governor closes the former quickly, the slow motion only being completely absorbed in the dashpot. Thus the discharge of the turbine can be quickly switched over from the turbine to the pressure regulator, and there reduced slowly in accordance with the setting of the bypass in the oil dashpot determining the rate of the closing motion.

The governor is installed on a special stand containing the flyballs and the relay of the governing device. The oil pressure is obtained from a central oil-pressure system located in the basement of the plant and is produced in the pumps of a rotary-gear type. The governor has a capacity of about 50,000 ft-lb., and is capable of moving the turbine gates over their full stroke in one second.

In a test the full load of 20,000 hp. was thrown off suddenly, causing the governor to close the gates quickly. The speed did not rise more than 12 per cent above normal, and the maximum pressure rise in the pipe line above normal did not exceed 5.5 per cent as against a guaranteed pressure rise of 15 per cent and a speed rise of 18 per cent. (*Power*, vol. 47, no. 6, February 5, 1918, pp. 174-177, 6 figs., *d*)

Internal-Combustion Engineering

Gas Producer with Floating Agitator. In a gas producer recently developed by the Chapman Engineering Company, of Mount Vernon, Ohio, a floating agitator is provided to stir up the fuel bed. The purpose of this device is to prevent the formation of clinkers by destroying blowholes and hot spots in the fuel bed.

It is claimed also that the agitator eliminates hand poking, as well as increases the capacity of the producer and the quality of the gas because of the frequent stirring of the entire surface of the firebed.

The agitator, Fig. 2, is built of heavy seamless tubing, the cross-arms being provided with stirring fingers of high-carbon steel. Cooling water is carried to the end of each finger by an inner tube. If desired, steam can be used for blowing on the fingers. The agitator passes through the fuel bed at the rate of five revolutions per hour. Motor drive is employed, the power being transmitted to a worm and wormwheel running into it.

The vertical or oating movement of the agitator resembles, on a large scale, the combined movement of a Yankee screw-driver. The vertical shaft of the agitator has a spiral driving head, with two large, screwlike spiral flanges that engage in sliding contact with two lugs projecting inwardly from the driving-wheel hub. Under ordinary conditions the wheel with the agitator revolve together, but if an obstruction is encountered, or the agitator becomes submerged too deeply in the surface of the firebed, it automatically screws up at once to a point where the forces are again in balance. Census of Internal-Combustion Engines. The *National Gas Engine Association Bulletin* has just made public data on the 1914 census of internal-combustion engines.

From this census it appears that in 1914 there were 809 establishments which reported the manufacture of engines, of which 243 made steam engines, 549 made internal-combustion engines and 52 made waterwheels, motors and turbines.

As regards internal-combustion engines, the great bulk of the engines produced were rated at having less than 50 hp. and less than 2 per cent as having more than 50 hp. More than nine-tenths of these engines had less than 10 hp. (*N. G. E. A. Bulletin,* vol. 3, no. 7, February 1918, pp. 2-4, *s*)

The Armour Institute of Technology Internal Combustion Engine Engineering Laboratory, Daniel Roesch. *The Armour Engineer,* vol. 10, no. 2, January 1918, pp. 102-106, 6 figs. Description of the new unit-type laboratory at the Armour Institute of Technology.

The Escape of Exhaust Gas in Two-Stroke-Cycle Engines, Guy B. Petter. In a two-stroke-cycle engine it is necessary to know the time required for the exhaust pressure to fall from its initial value to the atmospheric. Engines of the type referred to have inlet and exhaust ports in the cylinder wall which are uncovered by the piston toward the end of its outward stroke. The exhaust ports are given a "lead" so that the exhaust may get away by the time that the air ports open.

The velocity of escape of exhaust gas through the exhaust ports is affected with many uncertainties, and especially with the contraction of the gas by cooling. As, however, we wish

to establish a formula for purposes of comparison only, we assume that the fall of pressure is due entirely to the escape of gas through the exhaust ports at constant velocity.

Let v = constant velocity, in. per sec.
p = pressure (absolute) at the instant t (in seconds) reckoned from the moment of exhaust opening, lb. per sq. in.
V = capacity of cylinder and cylinder head above piston when the exhaust ports begin to open, cu. in.
A = area of exhaust ports open at the instant t, sq. in.
b = total width of exhaust ports, in.
m = engine speed, deg. per sec.
a = crank throw, in.
c = connecting rod length, in.
e = line joining crankshaft center to gudgeon pin, in.

Values with the suffix o are for initial conditions when the exhaust ports begin to open, and valves with the suffix f are for final conditions when atmospheric pressure is reached. It

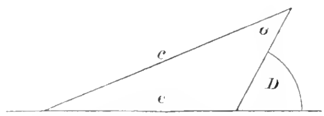

FIG. 3 EXHAUST PORT OPENING DIAGRAM

will be noted that p_f is atmospheric pressure in absolute units.

The total quantity of gas escaping is

$$\frac{p_o - p_f}{p_f} V$$

The quantity of gas escaping in a small interval $\triangle t$ at the instant t is

$$\frac{p}{p_f} vA \triangle t$$

and

$$\frac{p_o - p_f}{p_f} V = \int_{t_o}^{t_f} \frac{p}{p_f} vA\,dt \ldots\ldots\ldots\ldots [1]$$

Assuming from the evidence of the indicator card that the fall of pressure is directly proportional to the time, we write

$$p = p_o - \frac{(p_o - p_f)t}{t_f} \ldots\ldots\ldots\ldots\ldots [2]$$

Also, we may write with sufficient accuracy

$$A = \frac{A_f}{t_f} t \ldots\ldots\ldots\ldots\ldots\ldots\ldots [3]$$

Then we shall have

$$\frac{p_o - p_f}{p_f} V = \int_{t_o}^{t} \frac{p_o t_f - (p_o - p_f)t}{p_f t_f} v \frac{A_f}{t_f} t\,dt \ldots [4]$$

Integrating and applying the limits, we have

$$\frac{p_o - p_f}{p_f} V = vA_f \left[\frac{p_o}{p_f t_f} \cdot \frac{t_f^2}{2} - \frac{p_o - p_f}{p_f t_f^2} \cdot \frac{t_f^3}{3} \right] \ldots [5]$$

or

$$V = \frac{vA_f t_f (p_o + 2p_f)}{6(p_o - p_f)}$$

Consider the triangle in Fig. 3, formed by the crank a, the connecting rod c and the line e from the crankshaft center to the gudgeon pin. Neglecting the obliquity of the connecting rod, the depth of the exhaust-port opening at the instant t is $a(\cos D - \cos D_o)$ where D is the angle of the crank before dead-center position at the instant t, and D_o is the angle at the instant of exhaust-port opening.

Then

$$D_o = D - mt, \text{ or } D = D_o - mt \ldots\ldots\ldots [6]$$

And

$$A_f = ab\left\{\cos(D_o - mt_f) - \cos D_o\right\} \ldots\ldots [7]$$

Therefore

$$V = vabt_f \frac{p_o + 2p_f}{6(p_o - p_f)} \left\{\cos(D_o - mt_f) - \cos D_o\right\} .. [8]$$

From [8] we can compute v if t_f is known or t_f if v is known. The solution for t_f is best found graphically from the intersection of the curves

$$y = \frac{6(p_o - p_f)V}{vabt_f(p_o + 2p_f)} \ldots\ldots\ldots\ldots [9]$$

and

$$y = \cos(D_o - mt_f) - \cos D_o \ldots\ldots\ldots [10]$$

It is not to be supposed that these results will be physically correct, but they will serve for purposes of comparison. A mean value of v under ordinary working conditions can be obtained with the indicator card of any well-designed engine, taking t_f from the card and v from [8]. For the Petter crude-oil engine it is found to be in the region of 1650 ft. per sec. With this value of v it is easy to determine from Equation [8] suitable values for the width and lead of the exhaust ports. The relation

$$e^2 = c^2 - a^2 - 2ae \cos D$$

enables the position of the piston to be found for any crank angle D. (*Engineering*, vol. 105, no. 2714, January 4, 1918, p. 7)

350-B.HP. KROMHOUT MARINE ENGINE. Description of the largest Kromhout marine-type engine yet built. The general principles of construction of these engines were described in THE JOURNAL (January 1914, p. 022).

This engine, built in Amsterdam, Holland, operates on the two-stroke cycle, having four cylinders of 16¾-in. bore by 18¾-in. stroke, and develops its full power at about 240 r.p.m.

Starting and reversing of the engine is effected by means of compressed air. Referring to Fig. 4, the camshaft E is carried on the front of the engine, two cams being fitted for each cylinder to operate the air-starting and reversing valves. In addition, the camshaft has four cams for operating the four feed pumps. This camshaft is operated by the handwheel A by means of which a shaft can be moved in a fore-and-aft direction with the engine either stationary or running, the cams being so arranged that the movement of the shaft with the engine stationary admits compressed air for starting to the cylinder in the best position for commencing the rotation of the engine in the required direction, that is, to go ahead or astern. The engine has no dead center, but will start from any position, either ahead or astern. Air is admitted to the requisite cylinder through the valves G, the jackets of which are water-cooled, and immediately above each valve is mounted a small horizontal cone valve for indicating purposes.

The stroke of the fuel feed pumps and consequently the revolutions of the engine are regulated by the hand wheel D with the shaft operated by this lever being also connected to the governor F, so that the strokes of the fuel feed pumps are adjusted as required by the governor in the event of the load being suddenly taken off for any reason. The hand-wheel D operates a friction clutch used for disconnecting the propeller shaft from the engine when the signal "stop" is telegraphed down from the navigating bridge. The governor

then automatically comes into action and reduces the stroke of the fuel feed pump as necessary, so that the engine runs at about 100 r.p.m., at which speed the cylinder vaporizers remain at the proper temperature to keep the engine running and in definite time.

The governor *F* has several functions. It controls the revolutions per minute of the engine in two ways: first, as described, by reducing the pump stroke. At the same time, however, it throttles the scavenging in order to maintain the required temperature in the combustion chamber. It has also one particular advantage and that is, when the engine at sea is running at normal full speed of 200 r.p.m. and the propeller heaves out of the water, the governor at once prevents any tendency to racing.

The handwheel *J* enables the engineer to adjust the quantity of scavenging air in relation to the engine speed. There are also manual means for regulating the quantity of circulating water per cylinder, safety valves being provided to prevent any damage to the pumps should all four control valves be closed down inadvertently at the same time.

A special receptacle for methylated spirit is provided for the preliminary heating of the lamps: namely, a deep cup with a long handle which can be conveniently filled without danger of spilling, put into position and lit up without any chance of the spirit overflowing if the ship is rolling heavily.

The vaporizing arrangements are such that blow lamps are required for starting purposes only. Once the engine is running it will continue to do so at any revolutions between 100 and 240 for any length of time, and will pick up the full load immediately, even after running at the lowest number of revolutions for several hours. This is achieved simply by the fact that the quantity of scavenging air is always proportionate to the revolutions per minute. The engine requires no water injection.

An auxiliary set is supplied with each unit to drive the air compressor and possibly also the dynamo and bilge and ballast pumps. It is usually constructed on the same principle as the main engine, but without the reversing gear. (*The Engineer*, vol. 125, no. 3237, January 11, 1918, pp. 36-37, 3 figs., *d*)

Mechanics

Flywheel Design for Rolling Mills, G. E. Stoltz. The intermittent character of the rolling-mill load makes it necessary to have adequate flywheel capacity to equalize the power requirements and avoid heavy momentary overloads on the driving unit. The use of a proper flywheel effect permits, in certain cases, the installation of driving and generating equipment designed to carry a load of practically a constant character. Better overall economy is obtained, although the friction loss of the flywheel is added.

The writer discusses in brief the theory of flywheels.

The location of the flywheel is of importance. Logically, the flywheel should be placed as near the load as possible, but in some applications, such as sheet mills, this is not feasible as the mill speed is too slow. To properly equalize

the load on an 8-stand mill with the flywheel operating on the mill shaft at 30 r.p.m., a flywheel of 350 tons weight would be required. This is not practical, and on engine-driven mills, even with a comparatively large engine but a moderate-sized wheel, the engine does not fully compensate for lack of flywheel capacity, with the result that the speed drops considerably when peak loads are obtained. With electric drive the motor is usually operating at about 240 r.p.m. and a herringbone-gear unit is provided to obtain the proper mill speed. The flywheel capacity is usually obtained by placing the flywheel at each end of the pinion shaft. By doing this the total weight of the wheels would be 30 tons to provide the same flywheel effect as would be obtained if a 350-ton wheel were placed on the mill shaft. This has the disadvantage of transmitting all the peaks through the gears, but is the practical solution for this type of drive. Where sheet-mill engines have been replaced by motors with adequate flywheel effect, the monthly output may be increased approximately 10 per cent, which is due to the elimination of periods when the mill is slowed down sufficiently to interfere with its operation.

The conditions in the case of a blooming mill were investigated. The mill was of the three-high type, 28-in., operating at 70 r.p.m. Among other things, the writer calls attention

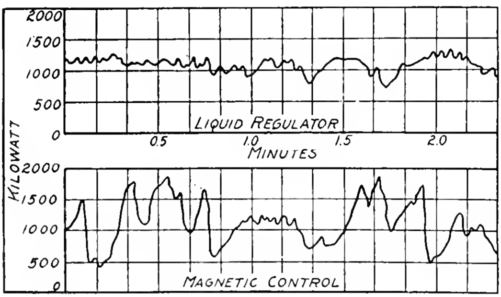

Fig. 5 Comparative Wattmeter Curves on Sheet Mill

to the fact that it is important to take under consideration the type of control used, as some utilize the flywheel effect to a better advantage than others.

From this point of view Fig. 5 is of interest. It refers to a sheet mill and shows the kilowatt input with notching in relays which regulates the amount of grid resistance of the secondary circuit of the motor, while the other curve is taken with the liquid slip regulator in the secondary circuit. The flywheel effect is the same, but the regulator does not come into action until the motor is fully loaded. With grid resistance in the secondary of the motor the flywheel and motor slow down in direct proportion to the load and when full load on the motor is obtained, the flywheel may be operating at 15 per cent slip and any further peak load cannot be absorbed by the flywheel to the same extent as when at its full speed. (*Iron Trade Review*, vol. 62, no. 1, January 24, 1918, pp. 272-274, 3 figs., *pe*)

Solution of Problems of Torsion by the Use of Soap Films, A. A. Griffith and G. I. Taylor. The equations which represent the torsion of an elastic bar of any uniform cross-section are of exactly the same form as those which represent the displacement of a soap film due to a slight pressure acting on its surface, the film being stretched over a hole in a flat plate of the same shape as the cross-section of the bar. Hence, by making appropriate measurements of soap films it may be possible to find the stresses and torsional stiffness of a twisted bar or shaft of any cross-section whatsoever.

Torsional problems are of great importance in aeronautical calculations. Propeller blades, spars, struts, etc., are subject to torsion, and at the same time have to be made of complex sections. It is therefore important to know the torsional stress occurring in them, so as to be able to use the minimum of material. The writers have developed a very simple experimental method for solving these problems.

A hole is cut in a thin plate of the section required to be investigated and a circular hole of a predetermined diameter is cut alongside it. The plate is placed in a box and soap films are stretched across the holes. The films are blown out slightly by reducing the air pressure on one side of them. By making suitable measurements of the shape of the resulting film surfaces it is possible to find the stresses in a bar of the given section in terms of the stresses in a circular bar of the same diameter as the circular hole when the two bars are twisted through the same angle per unit of length. By means of other measurements it is equally easy to find the ratio of the torques which must be applied to the two parts in order to produce the same twist in both.

In order to apply this method, apparatus is required with which three kinds of measurements can be made:

1 Measurements of the inclination of the film to the plane of the plate at any point for the determination of stresses. Optical reflection apparatus is used, the image of an electric-lamp filament being used in the film in such a way that the reflection ray is coincident with the incident ray, so that their common direction gives the inclination of the normal to the surface of the film.

2 Determination of the contour lines of the film. For mapping these lines a steel needle point, moistened with soap solution, is arranged to move about over the plate, its distance therefrom being adjustable by means of a micrometer screw. The point is made to approach the film until the distortion of the image in the latter shows that contact has occurred. This method of mapping contours is referred to here as the "spherometer" method.

3 Comparison of the displaced volumes of the test film and circular standard for finding the corresponding torque ratio. This is done by blowing the films up by running a known volume of water, or preferably soap solution, into the apparatus from a pipette.

The apparatus consists, therefore, of this spherometer for mapping the contour lines and the auto-collimator for determining the inclination of the film, this determination being usually confined to the determination of inclinations at given points on the boundary which are marked by scratches on the plate. For stress measurements the auto-collimator method is better than the contour-line method since it gives the inclination directly, whereas in the other case the inclination can only be found by a graphical determination.

Investigation of torsion problems by the soap-film method was checked by experiments of wooden beams of the same section. In one of these experiments a walnut plank was shaped so that its section was exactly the same as the hole in one of the test planes which represented a section in a propeller blade of fineness ratio 10.55, having its thickest part about one-third of the way from the leading edge. The value of the modulus of rigidity N was found by performing a torsion test on this plank, using the expression for the torque given by a soap-film experiment on the plate which was used in shaping the plank. N was found to be 0.1355×10^6 lb. per

sq. in. Five circular holes were then cut in the plank and their rigidities were measured. The mean value of N found in this way was 0.1387×10^6, or a difference of only 2.3 per cent.

When contour lines have been mapped the torque may be found from them by integration. If the graphical work is carefully done the value found in this way is rather more accurate than the one obtained by the volumetric method. Contours may also be used to find stresses by differentiation, that is, by measuring the distance apart of the neighboring contour lines: but here the comparison is decidedly in favor of the direct process, owing to the difficulties inseparable from graphical differentiation. The contour map is nevertheless a very useful means of showing the general nature of the stress distribution throughout the section in a clear and compact manner. The highly stressed parts show many lines bunched together, while few traverse the regions of low stress, and the direction of the resultant stress is shown by that of the contours at every point of the section. Furthermore, the map solves the torsion problem, not only for the boundary, but also for every section having the same shape as a contour line.

With the aid of simple apparatus of this kind the truth of theorems such as those contained in the following list may be readily demonstrated.

a The stress distribution—and therefore the torque—for any section is independent of the axis of twist. This is easily seen, since the shape of the soap film is completely determined by the boundary and the value of $4S/p$. Hence the torque on a number of bars clamped together at their ends may be found by adding the separate torques which would be necessary to twist each through the same angle. This, as in other cases, applies to torque only. It will be realized that in practice there will be bending stresses which must be taken account of in the usual way.

b Any addition of material to a section must increase the torque, and vice versa, so long as the distribution of material in the original section is unaltered.

c Any cut made in a section, whether it decreases the area or not, must decrease the torque.

d The stress at any point of the boundary of a section is never less than the boundary stress in a circular bar under the same twist, and whose radius is equal to that of the circle inscribed in the section which touches the boundary at the point in question.

More generally, if one section lie entirely inside another so as to touch it at two or more points, the stresses in the inner figure are less than those in the outer one at the points of contact; if the two figures are approximately congruent in the neighborhood of the points of contact, the difference between the stresses is small. The maximum stress in a section is not greater than $2aNr$, where a is the radius of the largest inscribed circle, unless the boundary is concave, that is, reëntrant.

e If a concave part of the boundary approximates to a sharp corner, the stress at this point may be very high, and if the curvature is infinite when the stress is also theoretically infinite, whatever be the situation of the corner with respect to the rest of the section. Actually, of course, if the material is ductile, we can only deduce that the stresses at such a corner are above the elastic limit.

f It is a consequence of (*e*) that it does not necessarily follow that the making of a cut in a section will reduce its strength, whether material is removed or not. As an example of this, one may quote the case of an angle iron in which the internal corner is quite sharp. It is well known in practice that this will often fracture. It may be strengthened, however, by reducing the section, planing out a semicircular groove at the root of the angle iron.

g There can be no discontinuous changes of stress anywhere in a section, excepting only those parts of the boundary where the curvature is infinite—concave or convex sharp corners.

h The maximum stress occurs at or near one of the points of contact of the largest inscribed circle, and not, in general, at the point of the boundary nearest the centroid, as has been hitherto assumed. An exception may occur, if, at some other part of the boundary, the curvature is—algebraically—considerably less; that is, the boundary is more concave than it is at this point.

i If a section which is long compared with its greatest thickness be bent so that its area and the length of its median line are unchanged, its torque will not be greatly changed thereby. For instance, the torsional stiffness of a metal plate is practically unaltered by folding or rolling it up into the form of an L or a split tube. Soap-film experiments show, in fact, that there is a diminution of less than 5 per cent when the inner radius of the boundary is not less than the thickness at the bend.

j The "unstressed fiber," which is situated at the point corresponding with the maximum ordinate of the soap film, is near the center of the largest circle which can be inscribed in the section.

In general, the inscribed circle has a maximum value wherever it touches the boundary at more than two points, and there is usually an unstressed fiber near the center of each of these circles. Between each pair of maximum ordinates on the soap film, however, there is a "minamax" point, which is near the center of the corresponding minimum inscribed circle. This fiber in the bar is also unstressed.

k The "lines of shearing stress" round the unstressed fibers of the first sort are initially ellipses, and round those of the second sort hyperbolas, from which shapes they gradually approximate to that of the boundary. Notions of this sort are useful in practice, because it is possible, with their help, to sketch in the general nature of the lines of shearing stress for any section.

The rest of the paper is devoted to the discussion of approximate formulæ for torques and stresses, and concludes with a mathematical appendix. Those who desire to follow the matter further will do well to refer to the original. (*Engineer*, vol. 124, no. 3234, December 21, 1917, pp. 546-547, 2 figs., eA)

Measurements

THE AUTOMATIC CONTROL AND MEASUREMENT OF HIGH TEMPERATURES, Richard P. Brown. From his experience in this country the writer claims that for industrial service an

instrument actuated by the expansion of nitrogen gas is the most satisfactory for temperature measurement up to 800 deg. fahr.

This instrument consists of a bulb of copper which is inserted in the heat and is connected by capillary tubing to an indicating or recording gage containing a helical expansive spring. The expansion of the gas in the bulb exerts a pressure in the capillary tubing which is conveyed to the spring in the instrument and the pointer attached directly to this spring moves across the scale or chart.

The writer discusses other instruments, such as thermoelectric pyrometers for use in measuring moderate temperatures where the measuring instrument must be placed at a considerable distance, or for measuring temperatures above the range of the gas-expansion instrument.

The writer has developed a new instrument which he calls the Brown heat meter and which is claimed to give greater precision in temperature measurements than is secured with the high resistance millivoltmeter.

In this instrument, in addition to the standard high-resistance millivoltmeter, is used an ordinary dry cell about $1\frac{1}{4}$ in. in diameter by $2\frac{1}{2}$ in. long, and a suitable rheostat to reduce the voltage of the dry cell from approximately $1\frac{1}{2}$ volts to a range from 0 to 60 millivolts, the voltage produced as a maximum by the thermocouples. In the operations adjustments are first made to insure that the voltage developed by the thermocouple is equal to the reduced voltage of the dry cell. Then the voltage of the thermocouple is cut out and the voltage of the dry-cell circuit read by direct deflection, which eliminates the line resistance entirely, just as a potentiometer gives a deflection indicating the actual temperature developed by the thermocouple at the moment of reading the instrument. It does not, however, indicate the fluctuation in temperature of the thermocouple, since it is the voltage from the dry cell that is being read. It is possible, however, to get this reading by connecting the thermocouple to the meter of the dry-cell circuit and noting whether the indications are the same.

The writer also discusses in detail automatic temperature control and the design of a temperature-signaling pyrometer, which latter is an instrument which will automatically signal by lights whether the temperature is too high, correct, or too low in any particular furnace. (*Proceedings of the Steel Treating Research Society*, vol. 1, no. 5, December 1917, pp. 32-35.)

Munitions

Shell Making by Improved Machine and Methods. Description of a method developed in a small machine shop to manufacture shells. A company in Ohio undertook the manufacture of shells for the Belgian army. The orders soon outgrew the capacity of the plant and a small shop was leased in Buffalo. In this latter plant the company manufactured shells of the French type having a longer taper and designed according to metric measurements. This required the improvisation of special machinery. One of the most interesting problems was connected with the process of nosing these French-type shells. The usual process of placing the shell forging centered and rough-machined vertically face down under a hammer or press and swedging it under a die could not be applied in manufacture under French specifications because of the thinness of the metal.

To meet this difficulty R. J. Wehland developed a machine for applying the force perpendicularly to instead of along the axis of the curve. This machine consists essentially of a steam hammer with two dies and a movable carriage which feeds the shell between the dies and rotates it between strokes of the hammer. The lower die is rigid. The upper one is impelled against the shell with a 1-in. stroke at the rate of 125 times per minute.

The shell base is held in the block on the carriage or feeding machine. Rotation is induced by a compressed-air motor working through a small pinion to the large gear which rotates the clamping device by which the shell is held. This rotation is at a constant rate, the entire carriage being moved forward by means of a large handwheel until the nosing attains the form desired.

The hammering is perpendicular to the long axis of the shell, and the only force delivered along the axis of the shell is that forward movement on the table by which the carriage is moved forward by the handwheel when the shell is fed into the dies.

This nosing machine may be used in connection with a forging press, as well as with the steam hammer. (*The Iron Trade Review*, vol. 62, no. 6, February 7, 1918, p. 373, 1 fig., *d*)

Gages and Gage Making for Munition Plants. (Prepared by the Library of the Engineering Societies.)

1913.—Inspection Gages for Remington Gun Parts, 1913. (*Amer. Mach.*, vol. 38, pp. 763-768.) Discusses the life of gages; describes counterbore gage, milling inspection gage and contour gage.

1915.—Machining Shrapnel Shells, 1915. (*Machinery*, vol. 21, pp. 638-639.) Detailed description of gages for British and American shrapnel shells.

1915.—Standardization of B. A. Screws, 1915. (*Mech. Engr.*, vol. 36, pp. 75-76.) Provisional conclusions reached by the Small Screws Sub-Committee of the Engineering Standards Committee, enabling the National Physical Laboratory to issue a list of dimensions which may be of service at the present juncture to persons using the screws and assist in obtaining interchangeable work.

1916.—Abbott, P. W., What's the Matter with Our Methods of Threading? 1916. (*Amer. Mach.*, vol. 44, pp. 173-175.) A study of the various elements entering into the production of good screw threads both internal and external; relates to accuracy in munition and other work.

1916.—Anderson, John R., Adjustable Limit Gage for Munition Parts, 1916. (*Amer. Mach.*, vol. 45, p. 339.) Illustrated description of a "bridge gage."

1916.—Baker, Donald, Manufacturing Parts of Type 80 Time Fuses, 1916. (*Machinery*, vol. 23, p. 297.) Gives details of gages used in testing and manufacturing fuse parts.

1916.—Bogart, F. H., Deceptive Working Limits on Munitions, 1916. (*Amer. Mach.*, vol. 45, pp. 1021-1023.) Analysis of working limits on various parts.

1916.—Booth, W. H., Limit Gage System in Principle and Practice, 1916. (*Mech. Engr.*, vol. 37, pp. 109-112.) Deals with design and materials of limit and screw gages; article written because the widespread interest in munitions has brought the question of limit-gage systems very much to the front.

1916.—Bogart, F. H., Production Gages, 1916. (*Amer. Mach.*, vol. 45, p. 1106.) Discusses their application to munition work.

1916.—Booth, W. H., Limit Gage Principles and Practical Applications, 1916. (*Canadian Machinery*, vol. 15, pp. 285-286, 343, 417-418.) On limit gages for various services, materials, designs, etc.; states that it is of interest in relation to munition work.

1916.—Colvin, Fred H., Caps and Base Plugs for Time Fuse. 1916. (*Amer. Mach.*, vol. 45, pp. 467-471.) Illustrated details of gages used.

1916.—Colvin, Fred H., Making Adapters for British Detonating Fuse. 1916. (*Amer. Mach.*, vol. 44, pp. 239-241.) Illustrated details of gages used for the adapters.

1916.—Colvin, Fred H., Making Copper Rifling Rings, 1916. (*Amer. Mach.*, vol. 44, pp. 678-679.) Shows a simple device for gaging ring used on the base of a shell to make it follow the rifling grooves in a gun.

1916.—Colvin, Fred H., Making Five Million Primers for Cartridge Cases, 1916. (*Amer. Mach.*, vol. 44, pp. 309-315.) Shows illustrated details of gages used.

1916.—Colvin, Fred H., Making the British Time Fuse Mark 80-44, 1916. (*Amer. Mach.*, vol. 45, pp. 367-374, 421-425.) Describes and illustrates tools and gages for making time fuses.

1916.—Colvin, Fred H., Making the Small Parts of the British Time Fuse, 1916. (*Amer. Mach.*, vool. 45, pp. 549-553.) Gages used for different parts of the fuse are shown.

1916.—Colvin, Fred H., Making Top and Bottom Rings for Time Fuses. 1916. (*Amer. Mach.*, vol. 45, p. 513.) Describes a variety of special gages for fuse work.

1916.—Colvin, Fred H., Manufacturing British 8-in. Shells in 4½ Hours, 1916. (*Amer. Mach.*, vol. 44, pp. 749-754, 807-813.) Illustrated details of gages used.

1916.—Colvin, Fred H., Manufacturing 120-mm. Serbian Shells. 1916. (*Amer. Mach.*, vol. 44, pp. 397-403, 453-458.) Details of the gages used, and of turning shells by power to try the gages.

1916.—Darling, H. M., Adjustable Limit Gage for Munitions Parts, 1916. (*Amer. Mach.*, vol. 45, p. 969.) Describes gage for testing straightness of small-size twist drills.

1916.—Darling, Herbert M., Making Accurate Templets (letter), 1916. (*Amer. Mach.*, vol. 44, p. 865.) Method for gaging the form of shells.

1916.—Dowd, A. A., Making Gages for Shrapnel Shells, 1916. (*Iron Trade Review*, vol. 59, pp. 17-20.) Economies for gage manufacture; examples of gages.

1916.—French Screw Gage, 1916. (*The Engineer*, vol. 122, p. 234.) Describes and illustrates a simple form of screw gage devised by M. Marre; relates to the adoption of the S. I. screw thread by the French Minister of War.

1916.—Glazebrook, R. H., Limit Gages, 1916. (*Engrg.*, vol. 102, pp. 224-225, 240-242, 236-238 and 252-254.) Illustrated article subdivided into gages for plain cylindrical work, screw gages, form, and position gages. States that the importance of subject has grown since the commencement of the war.

1916.—Lavender, J. H., Some Notes on Hardening Screw Gages, 1916. (*Engrg.*, vol. 102, p. 631.) Particulars obtained from experimental work extending over a period of six months.

1916.—Hamilton, Douglas T., Gaging and Inspection Methods, 1916. (*Machinery*, vol. 23, pp. 95-118.) The developments of interchangeable manufacture; the limit system and its advantages; difference between allowance, tolerance and limit; probable life of gages, etc.

1916.—Hamilton, Douglas T., Profile and Indicating Gages, 1916. (*Machinery*, vol. 23, pp. 208-219, 302-318.) Description of different types of gages working on the indicating principle which have been used with satisfactory results in the manufacture of munitions.

1916.—Hey, J., Two Gages for Use in Fuse Heads, 1916. (*Machinery*, vol. 8, p. 751.) Illustrated description of gages used in a British factory.

1916.—Loading Primer Bodies, 1916. (*Amer. Mach.*, vol. 45, p. 460.) Final assembling and gaging devices used for primers.

1916.—Manufacture of Mark II Gains for 18 Pdr. H. E. Shells, 1916. (*Canadian Machinery*, vol. 15, p. 277.) Describes gaging device.

1916.—Mawson, Robert, Making Bayonet Scabbards, 1916. (*Amer. Mach.*, vol. 44, p. 292.) Shows tension gage for bayonet scabbard.

1916.—Mawson, Robert, Making 1-lb. Cartridge Cases, 1916. (*Amer. Mach.*, vol. 44, p. 1032.) Illustrated details of gages for testing cartridge cases.

1916.—Mawson, Robert, Making the 18-lb. Cartridge Case, 1916. (*Amer. Mach.*, vol. 45, p. 381.) Shows details of the gages used.

1916.—Mawson, Robert, Making the 4.5-in. Howitzer Cartridge Case, 1916. (*Amer. Mach.*, vol. 45, p. 110.) Shows details of gages.

1916.—Mawson, Robert, Manufacturing the 1-lb. High-Explosive Shell, 1916. (*Amer. Mach.*, vol. 45, p. 158, 202.) Details of gages for screw-machine operations, for outside and inside threads, diameter and thickness of shoulder, length, and final test gage for shell diameters.

1916.—Mawson, Robert, Manufacturing 12-in. Shrapnel, 1916. (*Amer. Mach.*, vol. 44, pp. 537-542, 581-587, 625-630, 675-677.) Gives details of gages used; illustrated.

1916.—Mayoh, F. H., Gages in Modern Manufacturing Practice, 1916. (*Canadian Machinery*, vol. 15, pp. 307-308, 327-328, 364-365.) Illustrations in groups of a number of standard gages; includes gages for testing shrapnel-shell fuse rings.

1916.—Micrometer Limit Gage Attachment, 1916. (*Sci. Amer. Suppl.*, vol. 82, p. 325.) Brief description of "Apollo Mykarms," a small limit-gaging device invented and patented by a British government inspector.

1916.—Moore, J. H., Manufacturing Adapters for 18-lb. High-Explosive Shells, 1916. (*Amer. Mach.*, vol. 44, p. 413.) Illustrated details of gages used.

1916.—Olsen, L. E., Gage for Measuring Shrapnel, 1916. (*Amer. Mach.*, vol. 44, p. 412.) Gage illustrated has many advantages over the common saw-frame style or the vertical standard with pin-dropping device.

1916.—Pusep, Hugo F., Whitworth Thread-Gage Making, 1916. (*Amer. Mach.*, vol. 45, pp. 775-777.) Deals with precision gages for munition factories.

1916.—Screw Gages, 1916. (*The Engineer*, vol. 121, pp. 263-264.) Explains the necessity for accuracy in a gage, the errors which may occur in screws, and methods whereby these errors may be discovered and measured and avoided in future work. Abstract of paper written by the staff of the National Physical Laboratory; states that the screw gage plays a considerable part in munition work.

1916.—Shell-Test Scale, 1916. (*Amer. Mach.*, vol. 45, p. 173.) The purpose of the scale is to immediately indicate whether the shell is under or over the prescribed weight.

1916.—Suverkrop, E. A., Manufacturing British 18-Pounder High-Explosive Shells, 1916. (*Amer. Mach.*, vol. 44, pp. 495-499.) In the final government inspection shells are subjected to a very rigid examination in which all the gages previously employed are again made use of.

1916.—Training That Will Not Be Forgotten (editorial), 1916. (*Amer. Mach.*, vol. 45, p. 435.) Precision gage work on munitions.

1916.—Unification des Filetages, vis Mécanique, France, Adoption du Système International par le Service de L'artil-

lerie, Ministère de la Guerre, 1916. (*Bull. d'Encouragement pour l'Industrie Nationale*, vol. 126, pp. 74-110.) Describes standard for screw threads adopted by the Minister of War of France for use in the artillery service.

1916. United States Munitions, the Springfield Model 1903 Service Rifle, 1916. (*Amer. Mach.*, vol. 45.) General specifications and barrel operations, pp. 635-646, 679-689, 725-734; sequence of operations, including details of gages used. Operations on the barrel and fixed stud, pp. 679-689; illustrations of gages used. Operations on the bolt, pp. 987-994, 1033-1040, 1079-1087; shows sequence of operations and details of the gages. Operations on the receiver, pp. 813-821, 859-866, 901-911, 945-956; includes details of gages; illustrated. Operations on the sleeve, pp. 1123-1131, illustrated details of the gages.

1916. Viall, Ethan, Making 3-in. Russian Shrapnel in a Pump Shop, 1916. (*Amer. Mach.*, vol. 44, pp. 849-850.) Details of Russian shrapnel gages; illustrated.

1916. Wright, M. S., Tolerance System and Metric Conversion Table, 1916. (*Amer. Mach.*, vol. 45, pp. 702-704.) Tables compiled to assist in work necessary on gun construction.

1917. Alford, L. P., ed., Manufacture of Artillery Ammunition, 1917, N. Y., McGraw-Hill Book Co., Inc. Gives illustrated details of gages used.

1917. Baker, Donald A., Gages for Time-Fuse Parts, 1917. (*Machinery*, vol. 23, pp. 1089-1096.) Problems in the manufacture of gages for Russian time fuses and methods by which they were solved.

1917.—Bogart, F. H., Method of Machining the "85" Fuse Body, 1917. (*Amer. Mach.*, vol. 46, pp. 721-723.) Details of machining operations; illustrations of special gages, etc.

1917.—Bogart, F. H., Suggestions Relative to the Manufacture of Parts to Limit, 1917. (*Amer. Mach.*, vol. 46, pp. 667-671.) On the use of limits and limit gages; steps involved; requirements for expressing dimensions; essential and non-essential dimensions; examples of wrong dimensioning, etc., in the production of munition parts.

1917. Brooker, Arthur, Screw Thread Measurement, 1917. (*Engrg.*, vol. 103, pp. 113-118, 139-141, 165-166.) Definitions; method of measurement by microscope micrometer, diametral measurements by floating micrometer, optical projection apparatus, and measurement of pitch by mechanical means. Designed to be useful in manufacturing interchangeable parts in large quantities. (Same in *Mech. Engr.*, vol. 39, pp. 339-343, 353-355, and in *Post Office and Elec. Engrs. Jour.*, vol. 10, pp. 153-170.)

1917. Buckingham, Earle, American Industrial Progress as Revealed by War Orders, 1917. (*Amer. Mach.*, vol. 46, pp. 315-321.) Contrasts American and European manufacturing development and then briefly states the principles underlying interchangeable production.

1917. Chubb, I. W., Producing British Screw gages, 1917. (*Amer. Mach.*, vol. 46, pp. 593-594.) Notes relating to the methods followed by E. G. Wrigley & Co., in making gages for munition purposes.

1917. Cooke, A. G., W. J. Gow and W. G. Tunnicliffe, Manufacture of Gages at the L. C. C. Paddington Technical Institute, 1917. (*Jour. Inst. Mech. Engrs.*, Feb.-March, pp. 45-108.) Workshop details and methods of securing a high degree of mechanical accuracy under conditions of great urgency and without special equipment. Relates to the standardization of munition manufacture. (Abstracts in *Iron Age*, vol. 99, pp. 536-538, and *Model Engr., and Electrician*, vol. 36, p. 115.)

1917. Crompton, R. E. B., Notes on Screw Gages, 1917. (*Automobile Engr.*, vol. 7, pp. 35-37.) States that at the commencement of the war there was no satisfactory system in use for gage making; suggests that whole series of screws from 3-in. down to the tiny screws should follow one law for tolerances, modified only by considerations of the method of manufacture.

1917.—Dilrell, A. G., Ammunition for American Merchantmen, 1917. (*Amer. Mach.*, vol. 46, pp. 617-625.) Description and illustrations of gages for 6-in. shell for the U. S. Navy.

1917.—Erdman, A. W., Limits and Tolerances for the Manufacture of Munitions, 1917. (*Jour. Amer. Soc. Mech. Engrs.*, vol. 39, pp. 382-384.) Discusses some of the practical aspects of limits and tolerances, as customary applied. (Abstracts in *Amer. Mach.*, vol. 47, pp. 73-74; *Iron Trade Rev.*, vol. 60, pp. 1130, 1139-1140.)

1917.—Erdman, A. W., Limits and Tolerances in Munitions Manufacture, 1917. (*Iron Age*, vol. 99, pp. 1137-1138.) On relation of tolerances to weight; thread tolerances; individual judgment of inspectors; machine-tool limitation.

1917.—Forrest, James, Inspection of Munitions, 1917. (*Amer. Mach.*, vol. 47, pp. 763-764.) Inspection of munition work, and an example of gaging with minimum plug.

1917.—Gage Problem in Rifle Manufacture, 1917. (*Iron Age*, vol. 99, pp. 1199-1200.) States that there are not enough tool makers to equip private plants with fixtures.

1917.—How Gages for Big British Shells Are Made, 1917. (*Iron Trade Rev.*, vol. 61, pp. 17-22.) Describes the plant of Dove-Smith & Son at Niagara Falls.

1917.—Hamilton, Douglas T., Gaging and Inspecting Threads, 1917. (*Machinery*, vol. 23, pp. 477-486, 581-586.) Review of question of manufacturing tolerances on various elements of a screw thread as well as other points of importance.

1917.— Iler, William T., National Supervision of Gages, 1917. (*Machinery*, vol. 23, pp. 961-962.) Shows organization of proposed gage department of U. S. Munitions Board.

1917.—Macintyre, J. R., Production of Accurate Thread Gages, 1917. (*Machinery*, vol. 24, pp. 31-32.) Methods used in making thread-cutting and radius-forming tools and an angle-grinding fixture; current practice in the Remington Arms Co.

1917.—Macready, C. A., Elements of Gage Making, 1917. (*Amer. Mach.*, vol. 47, pp. 491-493, 661-664, 1112-1118.) On the principles and methods for recognizing and avoiding errors that have become habitual to gagemakers.

1917.—Masked Tolerances, 1917. (*Amer. Mach.*, vol. 46, pp. 694-695.) Method followed in making French high-explosive shell.

1917.—Modification of the Whitworth Screw Thread (letter), 1917. (*Engrg.*, vol. 103, p. 385.) Discusses proposals of W. C. Unwin, which are stated to be of interest to those manufacturing munitions.

1917.—Moffett, L. W. Toolmaker's Rôle in Wartime, 1917. (*Iron Trade Rev.*, vol. 60, pp. 929-931.) On the necessity of providing gages, jigs and fixtures for mass production.

1917.—Powell, H. J. Bingham, Inspection of Screw Gages for Munitions of War, 1917. (*Amer. Mach.*, vol. 47, pp. 1065-1073.) An attempt to assist screw-gage manufacturers in their work of making gages for munitions of war, which have to be accurate within very low tolerances.

1917.—Powell, H. J. Bingham, Screw Gage Measuring Machine, 1917. (*Amer. Mach.*, vol. 47, pp. 840-842.) Describes machine similar to one used in gage department of the British Ministry of Munitions.

1917.—Pusep, Hugo F., Practical Points in Flat-Gage Mak-

ing, 1917. (*Amer. Mach.*, vol. 47, pp. 369-372.) It has been demonstrated by all concerns engaged in producing war munitions in large quantities that the flat gage is an indispensable tool for taking measurements during the manufacture of primers, fuse bodies, time fuses, rifle parts, etc.

1917.—Screw Thread Measurements: Some of the Accurate Methods Used in Gage Making, 1917. (*Iron Age*, vol. 99, pp. 894-895.) Sketches showing definitions adopted for various portions of screw threads; method of measuring screw threads by microscopic micrometer and principle of the optical projection apparatus; in relation to the needs at the beginning of the war, when British manufacturers were compelled to make interchangeable parts in large quantities.

1917.—Sears, J. E., Manufacture of Screw Gages (letter), 1917. (*Engrg.*, vol. 103, p. 137.) On the work of the National Physical Laboratory since commencement of war; pitch measurement, diameter measurements, optical apparatus, automatic lapping of screw threads.

1917.—Standardization of Screw Threads, 1917. (*Engrg.*, vol. 103, p. 360.) A series of questions accompanied by table and drawing of the Whitworth thread, sent out by the Engineering Standards Committee, in coöperation with the Ministry of Munitions.

1917.—"Sponsel" Gun Barrel Calibrating and Straightening Machine, 1917. (*Amer. Mach.*, vol. 47, p. 744.) Describes a machine used for measuring and straightening the bore of gun barrels, etc.

1917.—Stărr, Adolph, Special Micrometer for Measuring Cartridge Tools, 1917. (*Amer. Mach.*, vol. 46, pp. 651-652.) Illustration of a micrometer designed for measuring drawing punches for brass shells and covers.

1917.—Suverkrop, E. A., Precision Thread Gages, 1917. (*Amer. Mach.*, vol. 47, pp. 265-271.) Details of making precision thread gages from the bar stock to the finished gage, in its relation to the manufacture of munitions.

1917.—United States Common Shrapnel and Common Steel Shells, 3.8, 4.7 and 6 in., 1917. (*Amer. Mach.*, vol. 46, pp. 1113-1118.) Specifications and operation lists for the different projections shown; includes gaging.

1917.—United States Munitions, the Springfield Model 1903 Service Rifle. (*Amer. Mach.*, vol. 46.) Floor plate, floor-plate catch, magazine spring, pp. 415-426; list of operations on parts that go to make up the magazine, illustrated; gages are included. Making the guard, pp. 287-293, 333-338, sequence of operations, including gaging; illustrations. Making the stock, pp. 1031-1041, 1079-1085, 1123-1129; sequence of operations, including gaging; illustrated. Movable stud; front sight and movable base; guard, gear, trigger and floor plate; leaf; slide and cap; draft slides; windage screw and butt plate, butt-plate cap, upper band, lower band, spring and swivel butt plate swivel, pp. 463-469, 551-558, 595-602, 641-647, 685-690, 725-735, 771-779; sequence of operations, including gagings; illustrated. Movable stud, pp. 463-469; includes illustrations of gages. Oiler and thong case, spare parts, container, screw-driver, pp. 947-953; includes illustrations of pages. Operations on the hand guard, pp. 67-73 (vol. 47), 111-118; list of operations and illustrations of gages used. Operations on the sleeve, pp. 19-27; illustrations of gages are given. Safety-lock spindle and plunger, pp. 245-250; small details requiring several interesting operations; some of the fixtures and gages are of special interest; illustrated. Stacking swivel, hand-guard clip, front-sight cover, cleaning rods, pp. 817-823; list of operations and illustrations, including gaging, of small accessories which go to make up the completed rifle. Striker, mainspring and extractor, extractor collar, ejector and ejector pin, pp. 111-119, 153-161; includes illustrations of gages. The bayonet, pp. 197-205 (vol. 47); show gages used in manufacturing the three kinds of bayonets used by the United States; the knife or regular bayonet and the large and small bolo bayonets. The cocking piece, pp. 69-76; illustrations of gages are given.

1917.—United States Munitions, the 3-Inch Common Shrapnel, 1917. (*Amer. Mach.*, vol. 46, pp. 353-377.) Includes illustrations of gages used.

1917.—United States Munitions, the 3-in. Common Steel Shell, 1917. (*Amer. Mach.*, vol. 46, pp. 486-507.) Includes illustrations of gages used.

1917.—United States Munitions, 3 to 6-in. Cartridge Cases, 1917. (*Amer. Mach.*, vol. 46, pp. 881-903.) Includes illustrations of gages.

1917.—Unwin, W. C., Further Notes on Screw Threads, 1917. (*Engrg.*, vol. 103, p. 289.) A comparison of British Standard Fine Threads (B.S.F.) and the International Metric Thread, which is now largely adopted for munition work in Great Britain.

1917.—Unwin, W. C., Suggested Modification of the Whitworth Screw Thread, 1917. (*Engrg.*, vol. 103, pp. 158-159.) Relating to the production of a great quantity of interchangeable mechanical parts for munitions. The advantage of clearance at the roots and crests of screw threads is examined and the effect of such a modification on the dimensions of the thread. (Abstract, Proposed Modification of Whitworth Thread, in *Iron Age*, vol. 99, p. 930.)

1917.—Van Wyck, J. R., Heat Treatment and Temperature Measuring of Shells, 1917. (*Amer. Mach.*, vol. 47, pp. 1087-1090.) Description of a successful method used in the manufacture of two million 3-in. Russian shrapnel shells.

1917.—Whitaker, E. W., Inspection of Gages for Ammunition, 1917. (*Iron Trade Rev.*, vol. 60, pp. 1242-1243.) The author shows the necessity of systematically checking all munition gages.

1918.—Powell, H. J. Bingham, Inspection of Screw Gages for Munitions of War, 1918. (*Jour. Amer. Soc. Mech. Engrs.*, vol. 40, pp. 108-109.) Discusses the question of pitch in screw gages.

1918.—American Society of Mechanical Engineers, Public Meeting of Gage Committee, culminating in a proposal to the Government to coöperate in munitions contracts by requiring certification of gages by Bureau of Standards, 1918. (*Jour. Amer. Soc. Mech. Engrs.*, vol. 40, pp. 70-72.) Recommends that gages be checked against standards under unified supervision.

Power-Plant Engineering

JOLIET POWER PLANT. Description of the power plant of the Public Service Company of Northern Illinois at Joliet, Ill.

The outstanding feature in the new plant is the high steam pressure used, which is 300 lb. at the turbine and approximately 325 lb. at the boiler, superheated 225 deg., or about 75 lb. higher than common in modern stationary practice.

Because of the density of the steam, extra heavy piping of relatively small diameter is used, all rigid construction being carefully avoided. The lengths of straight runs have been limited, and numerous long-radius bends are employed to provide for expansion.

Individual all-steel horizontal-tube economizers are used, said to be the first of their kind in the country. The construction of these economizers is similar to that of the B. & W. water-tube boiler without the drum. The headers are of rod steel and the tubes, which are 4 in. in diameter and 16 ft. long, of drawn steel 1/4 in. thick. As low temperatures are expected, the tubes are galvanized inside and out to guard against corrosion. The economizer is vertically paneled for three passes, the gases from the boiler entering at the front, and from the third pass rising vertically through the induced-draft fan to the stack. Although at the given rating the fan requires 94 hp., a 150-hp. motor was installed to provide for contingencies and to reduce upkeep to a minimum. Water to the economizer

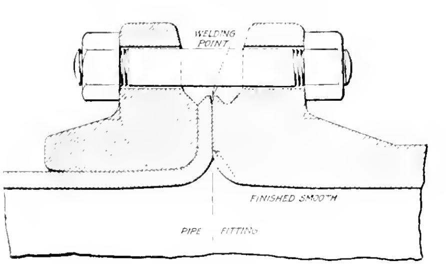

FIG. 6 SPECIAL WELDED JOINT FOR EXTRA HEAVY STEAM PIPING

enters at the bottom of the rear header and passes through 396 four-inch tubes, to leave at the top of the front header.

The economizer is placed above and integral with the boiler, the economizer tubes having a 5-deg. slope. There are no dampers between, so that the gases pass directly from one to the other, the furnace gases flowing from the economizers at such low temperatures as to permit unlined steel stacks.

Outside of the small stoker engines held as reserves for motor drives there is no reciprocating machinery in the station. With little exhaust steam available to heat the feed-water, provision is made to bleed steam under thermostatic control from the fourth stage of the main turbine, where the pressure is sufficient for this purpose. Another feature is to utilize the condenser for drawing boiler make-up from the fresh-water reservoir. The water enters the condenser, and with the air of the condensate pump is passed in the usual way to the heater.

Extra high high-pressure piping is used throughout with fittings of cast or forged steel. On steel pipes above 4 in. in diameter a special welded joint, shown in Fig. 6, is used. The pipe is extended through the flange and is belled out to form the face of the joint. The face is finished smooth and the edge beveled off to form a V-shaped groove to receive the welding metal. On fittings a face boss of extra thickness to form a welding surface similar to that in the pipe flange is provided. The weld is intended only to seal the joint, the bolts through the flange taking this stress. (*Power*, vol. 47, no. 4, January 22, 1918, pp. 108-113, 7 figs., *d*)

POWER PLANT INSTALLATIONS FOR BY-PRODUCT COKE OVEN PLANTS, George B. Evans. *Journal of The Engineers' Club of St. Louis*, vol. 2, no. 6, November-December, 1917, pp. 321-327.

Railroad Engineering

ALL-WOOD AND COMPOSITE HOPPER CARS FOR THE NORFOLK & WESTERN RAILWAY, B. W. Kedel. Description of two recent designs of hopper cars. The Norfolk & Western Railway is just beginning the construction of an order of 2000 hopper cars of 57 1/2 tons capacity, ten of which are being built entirely of wood, including the center sills and bolsters, for demonstrating the possibility of this construction for cars of such capacity. The rest will have steel center sills and steel bolsters with wood-frame construction for the remainder of the car.

The design of the all-wood cars is the result of the unusual steel market. The wood and center-sill members consist of a pair of through 6 by 12-in. sills spaced 15 1/2 in. apart, the bottom being located 2 ft. 6 7/8 in. above the rail, or 5 1/16 in. below the center line of the coupler, about as steel sills are ordinarily located and without the old-style draft chambers. Doweled to the inside of each of these along the bottom edge is a buffing sill of 4 by 8-in. dimension, these being consequently located almost symmetrically with the center line of the coupler and extending from one bolster to the other. Bolted between the main center sills over each truck is a gray-iron casting, which serves as a draft-gear backstop and the center channel tie casting, the center plate being cast integral with it and 4 by 8-in. buffing sills abutting on one of these castings at each end. This casting has shelf portions which underlie the main draft sills and support them independently of the bolts. The casting also has bracket portions which overlie the center sills and to these the sills are also hung by means of vertical bolts. Buffing forces are delivered to the draft by this casting and from it to the end grain of the buffing sills, and the buffing sills, in the same manner, transmit the force directly to the draft gear at the opposite end of the car and on to the next car.

The body of the car is anchored to the main 6 by 6-in. draft sills and these are bolted and doweled at intervals to the buffing sills to take care of the shifting of the body and the lading with respect to the buffing sills. The center plate being integral with the back-stop casting, the force from the inertia of the truck in buffing reacts at one end of the car against the ends of the buffing sills and at the other end of the car directly against the draft gear through this casting. The retarding force of a brake application is transmitted in the same manner.

The bolsters are each composed of two 6 by 20-in. yellow-pine timbers passing over the center sills and beneath the hopper chute, and these rest upon the top surface of the gray-iron center casting.

The design of the composite cars does not represent anything of unusual novelty. It is, however, of interest to note that iron castings are used quite extensively in the framing of these cars, the weight of the car being not much higher, however, than that of a steel car of equal proportions. (The first car turned out weighs 42,300 lb.)

It was contemplated on the steel center-sill cars to use wooden bolsters with the steel center sills, but because of the difficulty of making steel and wood work together with beam construction, steel bolsters are used with steel sills. The deflection of wooden beams is such that the center sills would be greately overstrained over the center plate before the bolster would have its proper load. Also the shrinkage of wood against the constant dimension of the steel would probably cause such variations in the loading at points as to entirely defeat the design. (*Railway Review*, vol. 62, no. 1, January 5, 1918. pp. 13-15, 2 figs., *d*)

Rail Creep. In a paper by Frank Reeves are described some simple experiments having for their purpose an explanation of the so-called creeping of rails. The broad conclusions at which the author arrived are: Creep of rails is due primarily to the deformation of the rail as the wheel passes over it. It may be likened to the movement of dough when rolled under a rolling pin. The more violent the deformation, the greater the creep. That is to say, creep is increased by (*a*) increasing the wheel load, and (*b*) by diminishing the rigidity of the rail, either by reducing its section or using a weaker material.

In a second paper, by Harry Powell Miles, are described briefly the effects which the direction and class of traffic and the alignments and gradients of the line have in producing creeping. The effect which creeping rails have on the constituent of the permanent way and the method of rectifying the positions of the rails after a creep has taken place are described, as well as investigations which the author made for a period of five years on a length of line consisting of 850 track miles of main and branch lines over which various kinds of traffic passed. The results of the investigation are not reported in the article. (*The Railway Gazette*, vol. 28, no. 2, January 11, 1918, pp. 42-45, 6 figs.)

The Effects of Water Scooping on Train Resistances, H. C. Webster. During its passage through the trough the scoop becomes a moving vane and is governed by the same principles as an ordinary turbine, except that the impact in the former case is caused by the collision of the moving scoop against the stationary volume of water and in the latter case by the moving water against the stationary or slowly moving vane.

Assuming that the scoop is moving at a velocity of V ft. per sec., and the area of the delivery pipe is a sq. in., then the resultant reaction of the scoop which constitutes the increased resistance of the train is

$$R = \sqrt{2} \times 62.4aV/144g\sqrt{(V^2/2)}$$

The writer gives the following table for trains moving with velocities between 25 and 60 miles per hour with a equal to 50 sq. in.:

Speed, m.p.h......	25	30	35	40	45	50	55	60
Resistance, lb......	901	1310	1779	2330	2940	3610	4320	5220

The relation between resistance and delivery-pipe area a is shown in the following table (V = 40 miles per hour):

a, sq. in........	35	40	45	50	55	60	65	70
Resistance, lb.....	1631	1860	2100	2320	2560	2800	3040	3260

If these data are plotted as a curve, as the writer does in the original article, a straight line is obtained which shows that in designing the scoop the minimum area is desirable consistent with the volume of water to be lifted over a given length of trough. (*Railway Engineer*, vol. 39, no. 456, January 1918, p. 4, 3 figs., *t*)

Locomotive Feedwater Heating. Description of a new system for preheating the water before it is admitted to the boiler of a locomotive. In this case exhaust steam taken directly from the steam chest or the exhaust passage in the cylinder saddle is used. It is claimed that the amount of exhaust steam taken in this way is not sufficient to interfere materially with the draft of the locomotive, while the feedwater temperature is raised from 150 to 180 deg.

With this system the injector is replaced by a new water pump which was developed for this particular work by the Westinghouse Air Brake Company.

This pump was modeled after a Westinghouse compressor. The steam end is that used on a standard 9½-in. compressor. The water cylinder is 6½ in. in diameter and double-acting. Tests made with this pump have shown that 50 lb. of water are pumped per lb. of steam used for operating the pump.

In the heater illustrated in the original article the exhaust steam from the steam chests is admitted at the top, allowed to circulate around the tubes which contain the feedwater, and passes out through the drain at the bottom. The water from the pump passes through the heater four times before it is delivered to the boiler. This is accomplished by means of walls in the headers at the end of the heater. One of the headers has three chambers formed by a wall extending horizontally across the header at the center and a vertical wall extending up from this wall. The other header has one vertical wall dividing it into two parts.

One of the most important features of this heater is represented by the agitators contained in each of the tubes in the heater. They consist of thin corrugated and spiraled strips of brass and their function is to so agitate the water as it passes through the tubes that every particle of it will come in contact with the hot tubes and absorb all the heat possible from the exhaust steam on the outside of the tubes. This agitation also serves to keep the tubes clean and free from scale. The higher the velocity of the cold water passing through the tubes, the more violent the agitation and the greater the amount of heat absorbed by the water. (*Railway Age*, vol. 64, no. 3, January 18, 1918, pp. 177-179, 3 figs., *d*)

The Creep of Rails, Frank Reeves. *Engineering*, vol. 105, no. 2716, January 18, 1918, p. 66.

Solidification as a Factor in Railway Valuation, H. M. Taylor. Discussion of methods for determining the value of "the hardening down" of a railroad, which means depreciation in the roadbed due to seasoning. The writer believes that it would be possible to arrive at a factor for determining closely the value of solidification by investigating the large companies which have lines long in service and lines newly built. (*Railway Age*, vol. 64, no. 3, January 18, 1918, pp. 176-179, 5 figs.)

Steam Engineering

Air Pumps. A sub-committee appointed by the Council of the North-East Coast Institution of Engineers and Shipbuilders recently presented its report on various methods of producing high vacuum.

This report was based on an investigation carried out at the works of Richardsons, Westgarth & Co., at West Hartlepool, England. The apparatus used in the investigations is of the composite type, such as used in college laboratories. It is shown diagrammatically in Fig. 7.

The tests were made on reciprocating air pumps working all wet, wet and dry, etc., and two steam jets. The pumps were

not used with the condenser, but with the receiver A. Into this receiver continuous streams of air and hot water to represent the condensate could flow at known rates, and it was the duty of the pumps to remove the water and maintain the vacuum in the receiver by withdrawing the air and vapor. As it was found in early tests that the aeration of the water was very irregular, it was decided to standardize it and for this purpose the de-aerator C was installed. It consists of a chamber exhausted by a steam jet to a vacuum of about 24 or 25 in.

The first tests were made with the plant arranged on the "ordinary wet system" with both barrels working. The results are shown at A, B and C in Fig. 8. To study the effect of the reduction in the volume of air, tests were then made

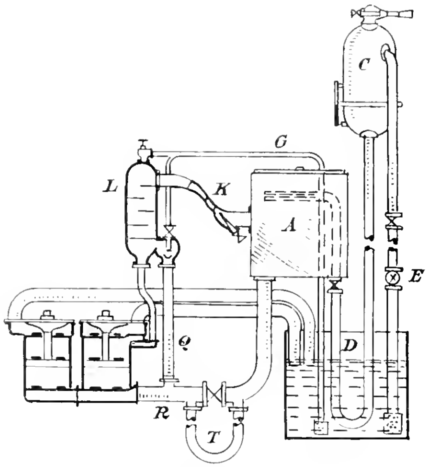

FIG. 7 DIAGRAM OF EXPERIMENTAL APPARATUS

with the single barrel, the results being shown in D. The next experiments were carried out with one barrel working wet and the other dry. The results obtained are shown at E, with cooling water at 50 deg. fahr., and F, cooling water at 70 deg. fahr.

Next "kinetic" combinations were tried out. Fig. 7 shows the connections used for the kinetic twin wet system. Two 1¼-in. steam jets working in parallel were fitted at K. The air withdrawn by these jets from the receiver was discharged into the small receiver and condenser L, the water being directed through the U-pipe T, which acted as a seal, making effective the head obtained by the height of the receiver above the foot valves and so preventing the passage back to the receiver of the air and vapor in pipes Q and R already compressed by the action of the steam jet. The results obtained are shown in G, for 60,000 lb. of condensate per hour, and H, for 10,000 lb. of condensate per hour.

The report states that the advantage obtained by the use of the jet is at once apparent, the vacuum approaching very closely to that ideally obtained in the absence of air, and an important portion of the curve being indistinguishable therefrom.

Two other arrangements of the kinetic system, namely, the kinetic wet and dry, were tried. The jet K, Fig. 7, and its condenser were moved to the left and connected with the barrel on that side and the U-pipe T was dispensed with. The right-hand barrel was run wet and the left-hand barrel dry. The line K, Fig. 8, shows the results obtained.

The tests have shown the greater efficiency of the steam jet. The complete report can be obtained from the Institution and costs half a guinea. (*The Engineer*, vol. 124, no. 3235, December 28, 1917, p. 557, 4 figs., *e*)

AIR PUMPS AND CONDENSERS. A new application of the steam-jet vacuum has recently been suggested by D. B. Morison. An extended investigation brought him to the conclusion that the steam jet is of advantage where the conditions are such that a poor vacuum meets the needs of the case. From his experience it appears that if a 25-in. or 26-in. vacuum will satisfy requirements, it can be obtained more cheaply and maintained more certainly by the use of auxiliary steam jets than in any other way.

A bad vacuum in a condenser, if not due to dirty tubes or hot cooling water, implies that much of the tubing is air-jacketed. In the commercial operation of reciprocating engines it is difficult to prevent air leakage, which impairs the efficiency of the condenser tubing. As the mixture of steam and air passes over the tubes, the steam as it condenses drops away as water, but the air remains behind, jacketing the tube. As a result, the lower rows of tubes in a reciprocating-engine condenser become quite ineffective.

Nevertheless, the lower rows cannot be abolished, because the air pumps can only remove a certain volume of air per minute, depending on their gross piston displacement, and also on the

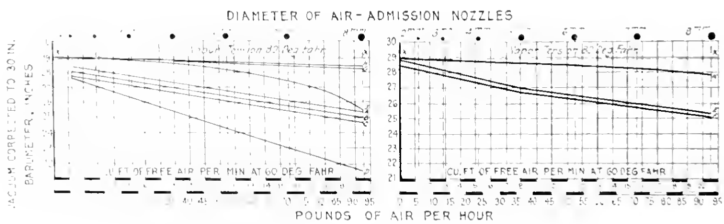

FIG. 8 DATA OF WEST HARTLEPOOL TESTS OF AIR PUMPS

temperature and pressure of the air itself. If the lower tubing be removed, the air will be delivered to the pumps at a higher temperature, and in that case either the piston displacement must be increased or the air must be delivered to the pump at a higher pressure, which means a worse vacuum in the condenser.

Here is to be found the advantage of the steam jet. If steam jets be interposed between the condenser and the pump, these jets which have a great volumetric capacity compress the

air into the pump suctions, so that a large weight of air can be abstracted with a very moderate pump displacement. Hence, the amount of the cooling surface in the condenser can be reduced 20 to 25 per cent, and the air pumps may also be made much smaller.

The experiments referred to in this article are those made by a sub-committee of the North-East Coast Institution of Engineers and Shipbuilders, and are reported in the next abstract. (*Engineering*, vol. 104, no. 2712, December 21, 1917, pp. 664-665, 2 figs., *e*)

Measuring, Purifying and Heating Feed Water, and Feeding Boilers. *Southern Engineer*, vol. 28, no. 5, January 1918, pp. 52-74, 36 figs.

Condensers with Seventy-Foot Water Level Variation, F. R. Brosius. Description of an installation where a type of substructure construction had to be adopted so as to insure a satisfactory supply of condensing water under unfavorable conditions and also support the great weight of the building and equipment on unstable ground. There are five condenser wells, with the intake well 86 ft. deep from the basement floor to the well floor and 60 ft. in inside diameter. Special methods for sinking the three larger wells had to be resorted to. It is of interest to note that part of the weight of the turbine rim rests on these wells. (*Power*, vol. 47, no. 5, January 29, 1918, pp. 142-144.)

CLASSIFICATION OF ARTICLES

Articles appearing in the Survey are classified as *c* comparative; *d* descriptive; *e* experimental; *g* general; *h* historical; *m* mathematical; *p* practical; *s* statistical; *t* theoretical. Articles of especial merit are rated *A* by the reviewer. Opinions expressed are those of the reviewer, not of the Society. The Editor will be pleased to receive inquiries for further information in connection with articles reported in the Survey.

LIBRARY NOTES AND BOOK REVIEWS

ARTICLES of interest from the Library of the four Founder Societies, selected list of accessions during the month, and reviews of books of special importance prepared by members of the A.S.M.E. and others particularly qualified.

Making the Library Serve Your Purpose

It is only by constant use that one begins to understand and appreciate into what an immense storehouse of knowledge the combined engineering societies' Library has now developed. For although a complete dictionary catalogue by authors and subjects may be available, and in addition many published bibliographies besides those compiled in the Library—all of which are at all times at the disposal of members visiting the Library—it would be a mistake to think that this machinery affords complete access to all the material.

Complete access could only be provided by a systematic index covering the whole of the books and periodicals, and such an index would hardly consist of less than twenty million cards, to approach anything like completeness; but the cost of this work is far beyond the present financial resources of the Library.

It is evident that a dictionary catalogue and bibliographies merely act as principal signposts through the labyrinth of knowledge constituted by the publications. But although no complete index is available, the Library possesses other means to get at what is wanted, i.e., a staff of searchers, who from long experience have learned to dig, and to dig deeply; and it is now a rare thing that a question is presented for elucidation and the inquirer is not satisfied. These searchers, making use of the signposts mentioned, act as guides in the innumerable directions indicated; it is they who finally obtain whatever information may be required.

Members of the engineering societies are at all times welcome in the Library, and welcome also to do their own digging, in which the Library staff will gladly assist them; but they will find that as a rule it is cheaper and much more convenient to have the digging done for them, for an experienced searcher will find a dozen references where an inexperienced man will find one.

Bibliographical work done by the searchers may serve a variety of purposes. It may be used for direct application in business; as a basis for technical papers, books, lectures; as a basis for inventions and patents; as a basis for legal action; or from the standpoint of economic, financial, and other aspects. It is therefore of the utmost importance that

all questions made the object of a search should be stated with the greatest accuracy, for only an intelligent question is likely to elicit an intelligent answer. In the great majority of cases it is unwise to ask the Library for all information on a given subject. In almost every case it is necessary to state limitations, such as: The search is to cover a stated number of years; the information is required for such and such a purpose; patents must be included or excluded, etc.; and this is the more necessary because it is generally in the more difficult questions that the assistance of the Library is required.

In view of the multitudinous ramifications of search work it is hardly possible to apply standardized methods to it, but it may be explained that the usual procedure includes the following steps:

a The inquiry is formulated exactly; if this is impossible, further information is asked of the inquirer.

b A bibliography is made to cover the subject exactly as stated, and is submitted to the inquirer.

c After perusal the inquirer may decide either to examine all the material or to select for further consideration such references as appear to him most suitable.

d In accordance with his decision the Library may be called upon to make photoprints, translations, or abstracts of the material selected, as the case may be.

e On receipt of these the inquirer is in a position to give the final answer to the original question, or he may determine in what further directions the assistance of the Library would be desirable.

Of course, the inquirer is at liberty to close the question at any of the stages enumerated. The Library also will tell the inquirer quite frankly when searching has probably reached the limits of usefulness, and it keeps an exact record of the extent of the searches made, so that any one may be continued at any time without duplication of the work.

An examination of the searches made in the Library would open the eyes of many as to the variety of subjects of inquiry. Although the searches are made under definite instructions from the Director with regard to methods, sometimes a question is received the answer to which lies entirely outside of the recognized routine, and to find an answer to some of these may tax to the utmost the ingenuity of the searchers. The following is an instructive example:

Some time ago a member presented the following question: "About fifteen to twenty years ago the sulphur beds of the island of Saba were worked; find the references."

In a case like this the card catalogues and most of the printed indexes are of little use, for even the encyclopedias dismiss a small place like Saba with a perfunctory note of about five or six lines, stating that it is a small island belonging to the Dutch West Indies, etc. The searcher experiences a vivid realization of the hopeless position of a man standing before a mass of books and not knowing where to attack them.

Reflection shows that the only way to attack such questions is to analyze them and think out a plan leading to the desired information. Thus in the Saba case the population would be very small and, therefore, mining operations of any extent would very likely be reflected in the figures. Again, the ore mined would presumably be exported, and being a poor ore by inference (for otherwise operations would be still going on), it could not stand the freight rate to Holland; it would most likely be shipped to the United States, also on account of geographical location and shipping facilities. Thus we obtain two sets of figures, population and imports to U. S., with which to begin operations. Which of these two sets is more likely to be available, to be more accessible and more accurate? Experience teaches that as a rule population figures are more reliable and more easily accessible, hence these were made the point of attack.

After considerable trouble, sufficient figures were obtained between the years of 1886 and 1913 to construct a curve, showing that a peak occurred about the year 1888. This was followed by a continuous decline, but preceded by rather small variations. Figures before 1886 could not be located, although it would have been interesting to follow out the variations indicated. Assuming that the year 1888, the peak of the reconstructed curve, was the year of the mining operations in question, this would agree fairly with the statement of the inquirer that they took place fifteen to twenty years ago, for in almost every case the time given is understated. The obvious course to follow now was, therefore, to examine the figures giving the imports into the United States for the corresponding period. Naturally, no geographical figures were available for a small place like Saba, the only statistics found including all the Dutch West Indies and Surinam; as for the subject sulphur, it was useless to think of tracing it in the imports.

The tables of imports found, however, proved to be disappointing, for they showed no unusual features; there was no peak corresponding to that of the population, nor was it perhaps reasonable to expect such an indication in view of the complexity of the figures.

According to the population curve it was useless to examine import figures for later years, so it was decided to work backwards at any rate to 1880, for there a decennial table for 1870-80 might be found. So it turned out to be, and the figures for 1875 indicated a fairly large import. What was more remarkable still, this import figure was isolated—it was preceded and followed by entire absence of imports. Although this absence might be satisfactorily explained in various ways, this was a good-enough indication on which to refer to mining magazines of that year in the hope of finding Saba, and so it happened. The article giving the information was found in the *Engineering and Mining Journal* for July 1875, vol. 20, p. 56.

It may be argued that going through the mining magazines at once would have led to the desired result, but in view of the fact that the inquirer was 22 years out in his statement, the fallacy of this is obvious. Besides, searching indexes for a number of years back has its difficulties; one is forcefully reminded of the philosopher's dictum, "Nothing is constant but change."

In the above case the train of thought led to the desired result; it might also have failed, but it is a fair example to show that no pains are spared in the Library to get at the information desired by members. Nor should the charge made by the Library for this class of work deter members from the full benefit of this unique collection of engineering literature, for the rate of $1.50 per hour charged is calculated to cover actual cost, so that no part of it will fall on the finances of the Library.

Inquiries from members are at all times welcome and estimates for work required will be gladly given so far as this is possible. Members who send orders to the Library can always keep control of the work to the extent of specifying the number of hours to be spent on their inquiries.

J. K.

BOOK REVIEWS

Machinery's Encyclopedia. A Work of Reference Covering Practical Mathematics and Mechanics, Machine Design, Machine Construction and Operation, Electrical, Gas, Hydraulic and Steam Power Machinery, Metallurgy and Kindred Subjects in the Engineering Field. Compiled and edited by Erik Oberg and Franklin D. Jones, in collaboration with many prominent mechanical and electrical engineers. The Industrial Press, New York, 1917. In 7 volumes, half-leather, 8x11 in. $36.

In spite of the unquestioned usefulness of encyclopedias of engineering, the English language is, unfortunately, poorly equipped with these summaries of current practice at the time. Such works as Spon's Dictionary of Engineering and Appleton's Cyclopedia of Applied Mechanics had great practical value in their day, as epitomes which saved reference to many individual treatises, but the time that has elapsed since their issuance has made them obsolete and created a need for some successor which would present present knowledge and current practice in concise and authoritative fashion.

The present work is intended to do this for mechanical engineers, especially for those interested in the design, construction and operation of machines and machine tools. To this end particular attention has been given to those processes and methods which the designer and manufacturer of machine tools use and to the best practice in machine-shop operation. The material included has been selected from the standard treatises and from the columns of *Machinery;* supplemented by numerous special signed articles on many phases of the general subject.

The noticeable features of these volumes are the length of the articles on important topics, the liberality with which they are illustrated, and the care that has been taken to include topics that are usually given scant attention. The article on Broaching, to take an example at random, fills 9 pages and contains 17 illustrations. Twenty-two pages are given to a discussion of Assembling. The question of Grinding and Grinding Machines occupies 50 pages, while the article on Autogenous and Electric Welding is 30 pages long. These articles give an idea of the scope of the work: the minor articles, however, are also useful, including as they do much material that usually is hard to find.

The final volume includes a comprehensive index, enabling one to find information not brought out by specific headings in the encyclopedia, and a Guide to Systematic Reading, outlining courses of orderly study on a number of topics, such as Mathematics, Forging Practice and Equipment, Finishing and Protecting Metal Surfaces, etc.

The mechanical construction of the set is good. The type, while small, is clear. The illustrations are reproduced from line drawings and are really illustrative. The pages open flat.

The producers of the work are to be congratulated upon the result of their endeavors. The set will prove of distinct usefulness in any library of engineering.

Harrison W. Craver.

The Principles of Iron Founding. By Richard Moldenke, E.M., Ph.D. McGraw-Hill Book Co., Inc., New York, 1917. First Edition. Cloth, 6x9 in., 517 pp., 45 illustrations. $4

Dr. Moldenke needs no introduction to those familiar with foundry practice, for he is one of the comparatively few men who have had to do with the marked advance of recent years in the art of producing sound castings. He is not only a well-trained technical man, but a successful foundryman as well, having had at different times the management of some of the largest foundries in this country producing gray iron, malleable and steel castings.

His fifteen years of acceptable service as secretary of the American Foundrymen's Association have brought him into close touch with all of the prominent founders of the world and provided the best possible training for writing a book on foundry work.

The author has undertaken to deal more or less completely with all of the principles underlying the processes involved in the art of iron founding.

It is rather unfortunate that there is nothing in the title to indicate that the author has not covered the whole field in his book. Either the title should be changed or this book should be marked Vol. 1, for the author notes that he is now at work on a second volume which will deal more particularly with general foundry practice.

This volume pays especial attention to the metal itself, to melting processes and to mixture making, and leaves nothing to be desired in the way of general information along these lines.

The problem of oxidized iron is given special attention and much new material is presented.

The book together with the promised second volume will unquestionably become the leading reference book on foundry practice and can be safely recommended to those seeking information on foundry work along either historical, scientific or practical lines.

The book should be in the library of all those interested in foundry work, as it is well worth owning. The facts and information which it presents are absolutely reliable and no other foundry book contains so much that is so.

William W. Bird.

Lubricating Engineer's Handbook. A Reference Book of Data, Tables and General Information for the Use of Lubricating Engineers, Oil Salesmen, Operating Engineers, Mill and Power Plant Superintendents, Machinery Designers, etc. By John Rome Battle, B. S. in M. E. J. B. Lippincott Co., Philadelphia, 1916. Cloth, 6 x 9 in., 333 pp., 114 illustrations and 16 pp. of ruled log sheets. $4 net.

Of very real importance are the 26 chapters devoted to the presentation of specific recommendations as to the proper and economic lubrication of air compressors, automobiles, internal-combustion engines, steam engines and turbines, refrigerating machinery, street and railway cars, locomotives, elevators, rolling-mill, textile, flour-milling and electrical machinery, etc. Wire-drawing and cutting-tool lubrication are also dealt with and chapters are given on lubricating oil and grease tests, lubricants and their properties, the cost of lubrication, etc. The book is self-contained, in that all of the mechanical reference data and tables required in working out lubricating problems are included. The author has been the mechanical engineer of a large oil company for many years and writes with the knowledge thus acquired.

Bulletin No. 99 of the University of Illinois Engineering Experiment Station contains the results of a series of experiments on the collapse of short thin tubes, made by Prof. A. P. Carman of the department of physics. The purpose of these tests was to find an equation by the application of which the pressure required to collapse a tube can be calculated when the dimensions of the tube and the elastic properties of the material are known. The bulletin gives a brief summary of earlier experiments on collapsing pressure, such as those of Fairbairn, Stewart and others, together with the formulæ developed by these investigators. Copies of this bulletin may be obtained gratis by addressing the Engineering Experiment Station, Urbana, Ill.

NOTES ON SHIPBUILDING

A Statement of the Primary Requirements for Successfully Building and Launching Vessels, Particularly in the South, One of the Vital Factors of the War

By F. J. French,[1] New Orleans, La.

I HAVE been asked to outline, in as few words as possible, the problems which present themselves to the prospective shipbuilder, rather with a view to promoting discussion on the subject with especial reference to local conditions in the South than with any intent to disseminate uninteresting and unimportant data on the subject of design.

Let us assume first that the shipyard owner is approached by a client who desires a vessel built for his particular service. His requirements will be primarily governed by ships that he already has in service; modified by the recommendations of his marine superintendent and his port engineer as to type of cargo, desired carrying capacity, draft, speed, and indicated horsepower, and further modified by that very misleading factor, "cost per deadweight ton," which is so widely quoted, regardless of speed required.

To illustrate the fallacy of using this unit of cost, take a vessel of 5000 tons deadweight capacity and assume, from data already at hand, a speed of 10 knots with an indicated horsepower of 1500. If the owner desires his ship to make 13 knots instead of 10, it will be found that (as for normal speeds the power varies with the cube of the speed) the required indicated horsepower will be in the neighborhood of 3300, or more than double the original figure, and the power-plant weight and cost will, of course, be in similar proportion.

The primary characteristics having been decided upon, the problem now passes to the builder's naval architect, who correlates all of the factors determined upon by the principles and sends to the estimator the weights, horsepower, etc., who in turn makes an estimate of cost upon which the contract is finally signed. It goes without saying that the estimate takes into full account whether or not the vessel is for bulk oil or molasses, which requires a much higher grade of workmanship than for package freight.

In addition to the particular requirements of the owners, it will also be specified that the ship is to be built to the requirements of either Lloyd's, The American Bureau of Shipping, or some other recognized classification society, and the surveyors of the chosen society will see to it that its requirements are lived up to. It may be pointed out in passing that the rules of the various societies specify, to the thirty-second of an inch, the size and thickness of all members entering into the structure of the ship, as well as the size and type of all fastenings; their rules being based primarily upon the theoretical strains experienced by ships subjected to the action of deep-sea waves, but modified by scores of years of experience covered by comprehensive reports of hundreds of catastrophes at sea, these reports being made by surveyors of the societies who are themselves seafaring men and who have carefully investigated the probable causes, and possible preventive measures, in each particular case.

Let us now assume that all the particulars of the ship to be built have been decided upon, the contract plans completed and the contract signed, and place ourselves in the position of the successful bidder. We find that we have on our hands a contract to furnish all material to construct, launch, power and equip a ship of, for example, 5000 tons deadweight, which is 350 ft. in length by 48 ft. in width by 28 ft. in depth, and has engines of 1500 to 2000 i.hp.

Perhaps, under present conditions, we have not done much more than select our site for building. If this has been done, it goes without saying that a frontage was chosen on as deep and wide a waterway as was compatible with financial and engineering considerations, and also that the site selected is reasonably accessible to a labor market.

The next step is to lay out our building ways to suit the water into which we propose to launch. We have now a choice of two methods of launching, i.e., stern first, or sideways. The stern-first method is universal at all Atlantic Coast yards and wherever the required width and depth of water is obtainable. The side lanching is largely confined to the yards on the Great Lakes and to other plants where for various reasons it is found desirable to build on the banks of a narrow waterway.

For the stern-first method the following conditions will govern: The building ways will be so located that the stern of the vessel will be close to the water's edge and 3 to 4 ft.

STEEL SHIP CONSTRUCTION AT VIOLET, LA.

above the ground. From this point back they will be given a rise of about five-eighths of an inch per foot, which would put the keel line at the bow of a 350-ft. ship some 21 ft. above water. A yard having a natural easy slope toward the water is therefore desirable as facilitating the construction of the underbody of the ship without the necessity of filling to the desired grade. The building ways consist of a series of blocks spaced about 4 ft. center to center and made up of 12 by 12-in. timbers 5 or 6 ft. long, set transversely and resting on piling.

The launching ways consist of two parts, the standing and the sliding ways, and are parallel to the center line of the ship and about one-third to one-half the half-breadth from it. They are constructed of heavy longitudinal timbers laid on piling and are usually given a camber or round-up of about a foot in their length for the purpose of overcoming the resistance of the water as the vessel nears the end of the ways.

A customary slope is about ½ in. per ft. at the bow of the ship, increasing to ¾ in. per ft. at the submerged end of the ways. This lower end should be 5 or 6 ft. below the surface and should be well supported by clusters of piles as, at the moment before the bow drops off the end, nearly half the weight of the ship bears on this point. The construction outlined is the common practice in tidewater yards and the datum plane taken is that of high tide.

It will at once be seen that we meet insurmountable obstacles when we propose to adapt this method to a river such as the Mississippi, where a variation occurs of twenty or more feet, and this so gradually that months may elapse between two successive periods of high water. If, for example, it has been planned to launch at high water and completion has been delayed for four or five months beyond the schedule, the builder is confronted with the alternatives of waiting for the next high water or flattening the launching ways and extending them some 400 ft. further, a procedure which would not appeal to the yard superintendent very favorably.

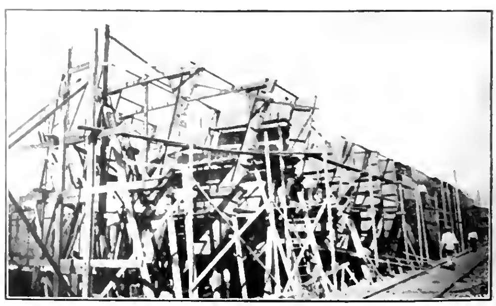
It has been suggested that ships could be built behind the levee, or in a sort of semi-dry-dock with gates, the grade being established midway between high and low water. A little consideration will show the impracticability of this scheme, for both high- and low-water conditions must be met. A levee must surround the building ways in case launching is to be at high water, and for low water nearly the same impractical length of ways would be required, as has been already described.

So far, then, as building on the Mississippi is concerned, it is believed to have been shown that the only practical location is upon a locked canal, and this, of course, involves a side launching. With this method, the keel is laid parallel to the bank, and instead of two sets of ways there are perhaps a dozen or more at right angles to the keel. The construction of the ways is similar to those already described, except that they may either be carried below the water surface (in which case the final camber is much greater than the longitudinal ways) or they may be stopped off short above the surface and the vessel "dumped" off. In either case the launching is a much more delicate proposition than the stern-first method, as all the ways must be released at precisely the same instant, any variance carrying the practical certainty of disaster.

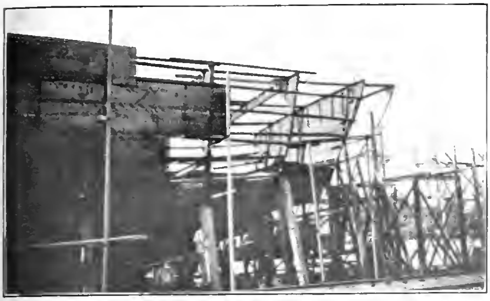
With either type of ways the maximum loading per square foot of sliding surface should not exceed 2½ tons, especially in warm weather, as heavier loading forces out the grease and chars the ways.

The next most important step is the ordering of the structural material, and this is done by the builder's superintendent from the contract plans, which consist of midship section, inboard profile, deck plans, bulkheads, and (if the vessel is to be of steel) the plating model. The latter is accurately made from the line drawing and on it are shown the exact sizes and thicknesses of all shell plates, as well as data concerning seam and butt riveting, doubling plates, longitudinals and transverse frames. All plates are ordered to within ½ in. of the desired size and are so shipped by the mills. Every plate, channel, or angle is inspected and tested at the mill by the surveyor of the registration society and a permanent record made of its characteristics as well as its location in the finished vessel.

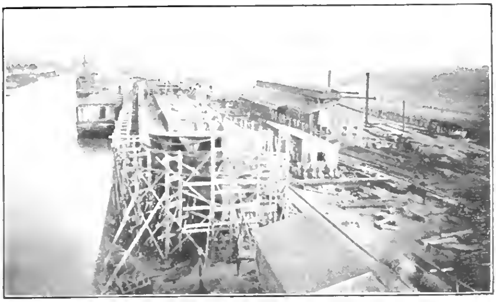
In the interval preceding the delivery of the material the loftsman is busy with his force laying down to full size and fairing the lines of the ship on the mold-loft floor. These



HULL 23, SEPTEMBER 29, 1917



Hull 23, October 1, 1917



Hull 23, December 4, 1917

STEEL SHIP CONSTRUCTION AT VIOLET, LA.

lines are the intersections of vertical transverse, vertical longitudinal, and horizontal planes with the outside shell of the ship, and the three views must be made to agree precisely or the resulting surface will be unfair. In some yards the lines are first drawn and faired to a quarter-inch scale in the drawing room, the offsets or ordinates from this set then laid down and refaired to a one-inch scale on a marble slab, and finally the offsets from the slab laid down and faired to full size on the mold-loft floor.

Methods have been evolved for deriving mathematically the lines of a ship of given characteristics, but as the simplest of these methods involves the use of formulæ with five variables they have not become altogether popular.

From the lines as drawn are now derived the exact contour of each transverse frame, as well as its bevel, the location of plating seams, and the traces of longitudinals and decks.

Templates of thin white pine are made of the frames and on these is shown all the information necessary to enable the shop to fabricate them. These templates then go to the bending floor, and the frames when bent and beveled go to the punch shop and are finally set upon the blocks and tied to the center keel and keelson plates which have preceded them. With the frames secured in place with longitudinals and temporary rib bands, templates are made from the skeleton for each shell plate and these templates applied to their plates which have now arrived from the mills. If the ship is known as a "full" ship and has a considerable percentage of parallel middle body, much of this work may be done in the loft and one template be made to answer for a dozen or more plates.

By intelligently applying the above principle to the original design a great amount of unnecessary labor may be eliminated, not only in the shell, but on bulkheads and decks as well.

The advantages above outlined would not, of course, apply in the same degree to the construction of a wooden vessel, as in this case once the frame templates are out it is largely a case of cut and fit for each timber and plank.

It is only reasonable to believe that by a judicious duplication of parts, by adhering as far as possible in a given yard to a given size and type of ship (as is now done in England), by reducing the number of plates which must be "lifted" from the ship itself, and by the introduction of efficient cost-keeping methods we will be able, when the present abnormal conditions have passed, not only to hold our own but actually to take the lead in this industry.

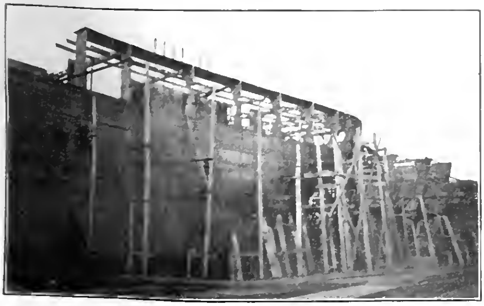
Turning for a moment to the power-plant side of the question, the builder and owner are faced by the necessity of deciding upon exactly the kind of plant desired. Let it be assumed that the indicated horsepower and speed have been determined. The combination of the two will give within reasonable limits the revolutions per minute of the propeller or propellers. There is then the choice of twin or single screws, with either compound or triple-expansion steam engines, turbines with gear reduction, Diesel engines or a turbo-electric system. In the particular case of four rather small vessels now building in the vicinity of New Orleans the advantage was found to lie with the latter system in price, weight and delivery, and that system was therefore adopted.

It is believed that there are very few, if any, shipbuilders in this part of the country who are at present equipped to economically construct marine engines, though it is hoped the opportunity will be afforded by the United States Shipping Board for local shops to become accustomed to this type of work so that they may intelligently and profitably undertake merchant work when the present shipping crisis has passed.

With regard to boilers, there are a number of shops in the immediate vicinity which are entirely competent to undertake the construction of fire-tube marine boilers to meet any requirements. As to type, the only fire-tube boiler in common marine use is the Scotch or wet-back type, in which the combustion chamber is integral with the boiler and is surrounded by water.

Of the water-tube type there are many makes, such as the Babcock and Wilcox, Heine, Sterling, Yarrow, Ward, etc., all of which are manufactured in both land and marine styles.

In direct connection with the choice of engine and boiler arises the question of whether or not it is desirable to superheat the steam, and if so, what type of superheater should be



HULL 23, STERN, NOVEMBER 29, 1917

adopted. With many of the water-tube boilers the superheaters are integral; that is to say, are really an extension of the tube surface. With the Scotch boiler, however, they are usually independent and are placed in the breeching.

In addition to the main power plant there will be required a main condenser with air and circulating pumps, boiler-feed pumps, fire pumps, anchor windlass, steam capstans, refrigerating plants, winches, and possibly a towing engine, as well as evaporators and distillers. These auxiliaries are fairly well standardized, and the purchaser is practically sure of getting what he pays for.

For the valves, pipe and fittings, of which there are thousands of dollars' worth on a ship of any size, some of our local houses are willing to exert themselves to the extent of quoting from a set of piping plans, with bill of material attached. Others prefer apparently not to do so when there is enough business coming their way without any effort on their part.

Having disposed in our allotted few brief words of yard, hull, and power plant, we have nothing left to think of but the arrangement of living quarters, carpenter work, joiner work, ladders and gratings, rigging, plumbing, ventilation, galley and linen stores, boatswain's stores, life boats and davits, carpenter's stores, fire-extinguishing apparatus, running lights, cooking and mess equipment, engine-room telegraphs, bilge and ballast system, and if we are so fortunate or unfortunate as to be building oil tankers, the entire cargo-handling system!

From the local builder's point of view there is one question which eclipses even the difficulty of securing delivery of materials under present conditions, and that is the problem of obtaining, in competition with the large northern yards, labor skilled in the art of shipbuilding. The ship carpenter of the days of the old wooden clipper ships, of whom was written, "Build me strong, O worthy master," is almost as extinct as the dodo bird, while ship fitters, ship smiths, loftsmen and other skilled workers are demanding and receiving wages that would have seemed affluence five years ago. At least one local yard (of which the writer has personal knowledge) is doing remarkable work in the training of colored labor for all except the most responsible positions in these trades, and is achieving excellent results in quality of workmanship.

To summarize briefly, it would appear that success of the southern shipbuilder rests on the following points:

1 Judicious selection of site
2 Rational layout of yard, with due regard to receiving, handling, storing, and routing of material
3 Foresight in design, with a view to standardization of all possible parts and the elimination of special and the use of stock fittings which may be purchased in the open market
4 An efficient cost-keeping system
5 The training of the labor which is locally obtainable and may reasonably be counted upon to remain
6 Promotion of a knowledge of the principles of shipbuilding by the establishment of classes in the public night schools.

[The paper was illustrated by lantern slides and was followed by discussion, in which several members of the Louisiana Engineering Society and of the A.S.M.E. took part.]

THE DEVELOPMENT OF CONCRETE BARGE AND SHIP CONSTRUCTION

By J. E. FREEMAN[1], CHICAGO, ILL.

THE need of ships has become increasingly evident to all, and that their construction in large numbers is a vital part of our war program is thoroughly understood. Judge George Gray, of Wilmington, Del., a member of the War Shipping Committee of the Chamber of Commerce of the United States, said recently in a plea addressed to the shipbuilders of the country: "There is no exaggeration in the statement that the necessity for an adequate production of ships is the most serious matter that now confronts us in this the greatest crisis in our country's history, or in the history of the world. We have entered this war for a just cause, and we must prosecute it with all our might and with all the resources of our country. Otherwise we cannot win it."

But speed is essential in securing tonnage, not only to replace submarine sinkings but to provide the great fleet of vessels to transport and maintain an adequate army in the field and still continue to keep our allies supplied with certain necessities. We need this fleet in the quickest possible time. "Make a bridge of ships to France" is the latest message from General Pershing and his men.

The tonnage of steel and wooden vessels now under construction in countless yards, to which are added ships transferred from coastwise and Great Lakes service, is still short of what is needed. To solve the problem requires the rapid development of all methods of shipbuilding, and it is for this purpose that reinforced concrete is now being considered and utilized to augment the tonnage under construction. The first seagoing vessel of concrete has made successful trial trips and vessels of larger tonnage are under construction both here and abroad.

The concrete-ship construction now under way in this country is of course largely experimental, assisted by experience gained in the design of steel and wooden ships; but there is every indication of ultimate success, and, as has been the case in other applications of concrete to new uses, experience with these first vessels will provide data to improve and clarify present ideas and to develop efficient methods of design and construction. Those who have thus far worked out designs for concrete ships have done so more or less independently, and up to the present time only meager information has been published regarding the data and calculations upon which their designs are based. But recent advices show that the Government is studying the problem, that a Department of Concrete Ship Construction has been formed by the Shipping Board, which is actively engaged in the development of a standard design for a concrete cargo ship of 3500 tons capacity, and drawings and specifications are expected to be ready in March. Provisional contracts have also been let to three companies for a number of 3500-ton vessels, plans and specifications for which must be approved by the Shipping Board. This has already been described in the technical press.

This present discussion of concrete ships and barges therefore must of necessity be rather general, presenting a brief review of progress in concrete-boat building from its earliest

[1] Portland Cement Association.

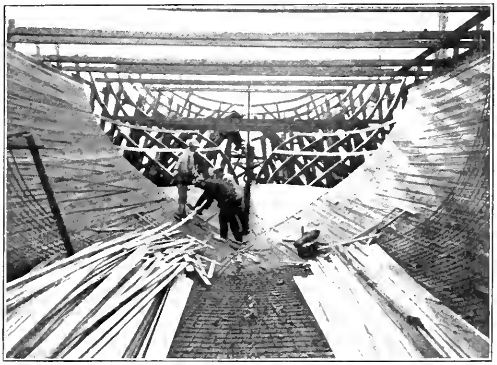
Abstract of paper presented at a meeting of the Engineering Society of Buffalo, February 13, 1918.

inception, describing some of the interesting work under way at the present time, and calling attention to the various problems entering into the application of reinforced concrete to such construction.

Singularly enough, boat building furnished one of the first uses of what would today be called reinforced concrete—a rowboat was built of this material in 1849, by M. Lambot, of Carces, France. This instance thus marked the starting point not only of concrete-boat building, but also of modern reinforced-concrete construction. This boat created considerable interest when exhibited by its builder at the World's Fair in Paris in 1855, and it was still apparently in excellent condition as late as 1903. Records are lacking, however, of any further development in France, until 1900, when a gravel barge 50 ft. long, 13 ft. wide and 3 ft. deep was built on the River Lozere.

In 1899 Carlo Gabellini, of Rome, began the construction of concrete barges and scows in Italy, and in 1905 a 150-ton barge was constructed for the city of Civita Vecchia. Later another barge was built for the use of the Italian Navy at Spezia; before acceptance, this barge was put to the severe test of being driven against piling and afterward being rammed by a steel tugboat. Up to 1912 about eighty vessels had been constructed by the Gabellini concern.

Center to Stern of Reinforced-Concrete Boat Under Construction at Redwood City, Cal.



Construction of Concrete Cargo Steamer at Barcelona, Spain

Beginning as early as 1887 small concrete barges of 11 tons capacity were built successfully by the Fabrieck van Cement-Ijzer Werken, in Holland, followed later by larger craft of 55 tons capacity with a cellular construction formed by longitudinal and transverse partitions or bulkheads and reported as making the boat practically unsinkable.

In Germany a 220-ton concrete freighter was built in 1909. The major portion of the hull had parallel sides, but was so shaped that the lines were fairly good and the water resistance was decreased below that of a rectangular barge. This vessel also had watertight bulkheads. It is reported that since 1914 Germany has built numerous concrete barges and some concrete ships.

In 1912 a reinforced-concrete scow or pontoon was built by the Yorkshire Hennebique Contracting Co., Ltd., of Leeds, England, for maintenance work on the Manchester Ship Canal, in accordance with the requirements of the canal company's engineers. The craft is 100 ft. by 28 ft. by. 8 ft. 6 in. deep from main deck to keel, drawing about 6 ft. 6 in. when loaded to capacity (about 224 tons). It carries centrifugal pumps, steam winches, engines, boiler and coal supply. The hull consists of a series of watertight compartments, so designed that if the exterior shell were destroyed the body of the hull would still remain afloat. The compartment containing the boiler plant has a 4-in. floor and heavy beams supporting coal bunkers and boiler, but otherwise the general construction is light; the outer skin of the hull is only 3 in. thick. All watertight compartments were carefully tested by filling them with water. The scow has been in almost constant service since construction with small expense for repairs.

In 1910 the building of concrete barges was undertaken on this side of the Atlantic. On the Welland Canal an 80-ft. barge of 200 tons capacity, called the *Pioneer*, was built for maintenance work. Design and construction were carried out under the supervision of J. L. Weller, St. Catharines, Ont., engineer in charge of the canal work. The barge has a beam of 24 ft. and depth of 7 ft., with rounded bow and a square stern. The hull was divided into eight compartments by longitudinal and cross bulkheads, double hatchways at stern and openings through the cross bulkheads giving access to all parts. The deck, bottom, sides and bulkheads are $2\frac{1}{2}$ in. thick, reinforced in two directions with $\frac{1}{4}$-in. steel wire and strengthened by the bulkheads and by beams and posts of reinforced concrete about 6 by 8 in. in size. Two 6 by 8-in. oak timbers serve as fenders. The barge draws 2 ft. 8 in. light (130 tons displacement), and when loaded to capacity has a draft of 6 ft.

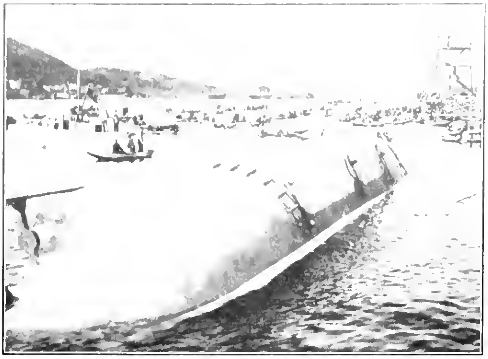
This barge has been in almost constant service since construction with practically no maintenance charges and is still in excellent condition. At times she has been loaded with 10-ton carloads of rubble stone dumped from a height of 12 to 15 ft. directly on to the $2\frac{1}{2}$ in. deck, the full load starting at one end.

On the Panama Canal three concrete barges 64 ft. long, 24 ft. beam and 5 ft. 8 in. deep were built in 1910 to carry dredging pumps, forming part of a plant used for hydraulic excavation at the site of the Miraflores locks. They were launched in the spring and summer of that year. Reinforced concrete was used because it was impossible to obtain skilled labor and suitable material for the construction of steel or wood barges within the time required. The walls and bottom were made $2\frac{1}{2}$ in. thick—two 3-in. bulkheads extending from bow to stern, making three compartments. Longitudinal beams at top and bottom of bulkheads and side walls, with posts at 10 ft. intervals, cross-connected at posts by beams with knee braces, comprised the general framing plan. The shell was a 1:2 mortar plastered on the steel skeleton of rods and mesh. Interior

members were 1:2:4 concrete cast in forms. The draft was 3 ft. 5 in. with a total load of about 140 tons.

Following this work, in 1913 and 1916 a number of reinforced-concrete pontoons were built at Panama to serve as landing stages for boats up to 65 ft. in length, and have been in regular use since. These pontoons are 120 ft. long, 28 ft. wide and 8 ft. deep.

Oscar F. Lackey, when harbor engineer of Baltimore, developed a system of construction which was first used in 1909 to build a landing stage for small boats, and then in 1912



LAUNCHING A 200-TON CONCRETE LIGHTER AT PORSGRUND, NORWAY, JULY, 1917

was applied to building a 500 ton concrete gravel scow for the Arundel Sand and Gravel Company of that city.

This latter craft has a length of 113 ft., a breadth of 29 ft. and a depth of 10 ft. 6 in. Four longitudinal bulkheads and five cross bulkheads divide it into twenty watertight compartments. The shell and deck are supported by a series of vertical and horizontal beams, the slabs varying from 3 in. to 5 in. in thickness, reinforced with plain bars running in both directions. The hull was built between forms and a very rich concrete mixture was used, with coarse aggregate of about $\frac{1}{2}$-in. maximum size. With the intention of facilitating towing, the sides were rounded on about a 6-ft. radius and worked into sloping ends which were carried back much further than in the ordinary scow. Light, the scow draws 4 ft. 3 in., and when loaded to its capacity has 1 ft. freeboard.

This scow has been in daily use ever since construction, is perfectly watertight and has withstood the roughest kind of handling. It has required no pumping out.

The full rounded sides and ends developed some undesirable features under load in a high sea or strong wind and in berthing. Consequently, in two other scows that were built in 1913 and 1915, respectively, a design more along the lines of the ordinary wood scow was utilized. These later scows were also cheaper to construct, form work being less expensive and placing of reinforcement easier. In the second of these scows five longitudinal and five cross bulkheads were used, and a combination of bars and expanded metal used for reinforcement. In the third scow an intermediate deck was introduced. The difficulties found in towing the first scow were eliminated and the draft reduced to 3 ft. 10 in. This was slightly in excess of a timber scow of the same capacity, but the concrete scow towed as easily when new, according to Mr. Lackey, and more easily than the other after a few months' service because of the lack of formation on the bottom.

One of these scows is used by the Raymond Concrete Pile Co., at Baltimore, a letter from which company last July stated that it had been very satisfactory in every respect and there had not been a dollar's worth of repairs since the scow was placed in commission.

Considering that these scows are watertight, do not require scraping, calking or painting, or maintenance other than repairs to the wooden-fender system, and crediting the cost of time that would otherwise be lost in making such repairs, the concrete scow becomes a decidedly interesting proposition.

England and France have recognized the utility of barges and self-propelled lighters of concrete. Last spring an English periodical mentioned a French company formed for the purpose of building seagoing concrete lighters; later pictures were shown of concrete boats under construction on the Paris Ship Canal. The Under Secretary for Sea Transportation and Merchant Marine in France was recently quoted as saying that very interesting experiments had been made with two concrete lighters in service. This has doubtless led to the building of more craft near Bordeaux, also several twin-screw vessels at Ivry-on-Seine, recent press photographs of which give a general idea though details are lacking. An English paper reports orders on hand from the French Government for several hundred concrete barges. Several English firms have begun the building of motor-driven barges of concrete, and more recently a concrete shipbuilding company has arranged for a yard at Dundee, Scotland.

James Pollock & Sons Company, a London firm of naval

LAUNCHING A 200-TON CONCRETE LIGHTER AT PORSGRUND, NORWAY, JULY, 1917

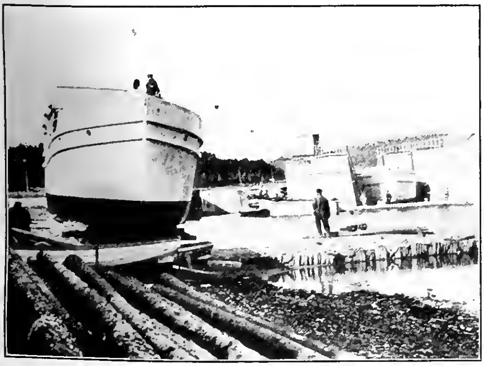
architects and engineers, has drawn plans for a fleet of small coasting vessels of reinforced concrete, the first vessel laid down having a length of 92 ft., beam 19 ft. and depth 10 ft. Power is obtained from a 120-hp. oil motor. In coasting vessels which need not make over 8 miles per hour, the use of straight lines would not necessarily be a handicap, and these concrete vessels have therefore been designed with such lines wherever possible to reduce form work, simplify bending, placing of reinforcement, etc. This firm is now drawing plans for larger vessels of 500 to 1500 tons cargo capacity.

A letter just received from a former Chicago engineer, now in England, advises that he has recently designed a number of barges and seagoing vessels of reinforced concrete and is at present interested in the building of ten such seagoing barges of 1000 tons capacity. A recent statement by the First

Lord of the Admiralty that ferro-concrete barges up to 1000 tons were being built in Great Britain possibly refers to this same work.

A Spanish reinforced-concrete cargo boat will be launched shortly by a corporation known as Works and Pavements, of Barcelona, the first firm in Spain to engage in the construction of concrete ships. The length of the first vessel is about 110 ft., beam 23 ft. and depth 11½ ft. Power will be supplied by a 120-hp. Diesel engine, and in addition sails will be fitted to the vessel. The company plans to construct during 1918 a gross tonnage of 40,000 in standard ships of 300, 500 and 1000 tons each, while ground has been acquired to permit later the construction of thirty boats at a time, some of which are planned to be of 6000 tons capacity. This company uses a mixture of 650 kg. of cement to 1 cu. m. (1:2½) of inert materials (gravel and sand of three sizes) so as to obtain, in its own words, "a dense, impermeable mixture that will permit also constructing the thinnest permissible section with a view to reducing maximum weight and thus obtaining the greatest possibilities in the way of speed." The concrete is considered to develop a compressive strength of 271 kg. per sq. cm. (approximately 3800 lb. per sq. in.) in 90 days, and a working strength of 76 kg. (approximately 1100 lb. per sq. in.) has been adopted.

Yet this work in shipbuilding is not entirely new, for Norwegian and Danish firms have already built and launched several concrete ships and self-propelled lighters of 200 tons capacity and now have larger craft under construction. The Fougner Steel-concrete Shipbuilding Company, one of the first in the field, has a plant at Moss, established in 1916. Following successful experiments made by Mr. Nic. K. Fougner with a 50-ton concrete lighter at Manila in 1914, the company has built some eighteen or twenty reinforced-concrete lighters and tow boats. These lighters have capacities of 100 to 200 tons, the later types having more the barge shape. Some are in use along the Norwegian coast and others have been bought by the Norwegian Navy. A loading test recently reported of a 64-ft. 100-ton lighter over an unsupported length of 40 ft. showed a deflection of about 0.6 in. under a uniform



Launching the 200-Ton Seagoing Concrete Motorship *Namsenfjord* at Moss, Norway, July, 1917. Concrete Floating Drydock in Background

load of 16 tons, in addition to the weight of the lighter itself which was 58 tons. The surface is reported to have shown no sign of cracking or indications of flaws.

The structure consisted mainly of keelson and ribs of reinforced concrete with a thin shell of concrete plastered on expanded metal or cast around rods, and this method of construction has been applied to the first sea-going concrete ship, the *Namsenfjord*. This vessel was launched last summer, was given a high rating by Lloyd's and is now in service for coastwise traffic. The vessel has a cargo capacity of 200 tons on 9½-ft. draft and is driven by a Bolinder crude-oil engine of 80 hp. at a speed of about 7½ knots. The length is 84 ft., beam 24 ft., molded depth 11½ ft. Larger ships of 600 to 1600 tons are now building, but their general design is much the same as that of the *Namsenfjord*, briefly described as follows:

There is a keelson of reinforced concrete with cross frames every 4 ft., the frames being continuous along sides and bottom and tied to the keel by the rod reinforcing. Particular attention is paid to continuity of reinforcement for these frames, and knee braces are provided at corners of the hull. The skin is 3 in. thick, reinforced with mesh and having a longitudinal beam at the outer corners of the hull. Concrete-filled pipes are used for center posts at intervals. The hull is divided into watertight compartments by transverse bulkheads of concrete reinforced with metal lath. The cabin is of wood and wood fenders are provided.

In building the hull, the bottom is cast in forms up to the top of the longitudinal hull beam previously mentioned. For the side of this size vessel the reinforcement and metal lath is set up for the total height and concrete deposited between the two sets of lath which act as a form; the outside and inside surfaces are then plastered. For larger boats this procedure is altered, using shorter heights of lath or casting the main frames in forms. Care is taken to make the construction continuous however, so that no joints are left in surfaces exposed to water.

In the earlier craft 1:1½:2 or 1:1½:2½ concrete was used with ½-in. maximum size aggregates, but later developments showed a 1:2 mixture with ¼-in. material worked better around the reinforcement.

The company has a contract for a 4000-ton ore carrier 254 by 40 by 19½ ft., equipped with two 300-hp. Diesel engines, and only awaits authorization by the Norwegian Marine Registry before proceeding with the construction. It has also constructed for a Christiania firm of yacht builders a floating drydock of concrete—the first of its kind—with a lifting capacity of about 100 tons, which suggests another field for development in the present emergency. The dock is 80 ft. long, 38 ft. wide and 20 ft. high, with a sill 4½ ft. thick and side walls 6½ ft. wide at the bottom. There are nine watertight compartments. The dock accommodates a vessel 75 ft. by 25 ft. and is equipped with an electrically operated centrifugal pump by means of which a 100-ton load can be lifted from the water in one hour. The Fougner Company is reported to have plans for larger docks up to 15,000 tons capacity.

The ships built according to the Fougner system have a ratio of dead weight to displacement from 12 to 15 per cent less than for steel ships, that is, their displacement is more for the same cargo-carrying capacity. [By dead weight is meant the cargo-carrying capacity expressed in tons, usually in terms of long tons (2240 lb). The displacement of a ship is the weight of water she displaces, and covers the weight of the ship itself plus the dead weight.]

The Fougner Company has established an American branch in New York, and is reported to have a contract with the Shipping Board for several 3500-ton ships contingent upon the success of the first vessel. It is stated that the Ferro-Concrete Shipbuilding Corporation, of New York, and the Liberty Shipbuilding Company, of Boston, also have similar contracts.

Another Norwegian company actively engaged in concrete-boat building is the Porsgrund Cement Construction Works, at Porsgrund. After the construction of a bridge pontoon in 1913, experiments were begun with a view to simplifying the form work and construction methods, as a result of which it was determined to build the boats upside down and launch them in that position. Following successful experiments with a 9 ft. model, a 200-ton barge was built and launched last summer. The barge has a length of 98½ ft., beam 19½ ft. and molded depth of from 9 ft. at center to about 10½ ft. at bow and stern. It will be equipped with a 70-hp. motor. Other lighters are in process of construction having capacities of 600 to 1000 tons. The general design follows that of a framed steel ship. The righting of the boat took about 20 minutes, an ingenious arrangement of inner airtight compartments making the craft practically self-righting.

The principle may be briefly described as follows: The inner mold is divided into compartments; when the vessel enters the water the air gradually escapes from the middle and upper two compartments through vent pipes, and the vessel losing buoyancy gradually sinks to a point of maximum submergence. The lower side compartments never being flooded, the vessel is in a state of unstable equilibrium, the center of gravity being considerably higher than the center of buoyancy. If the vessel now heels slightly to one side or the other, a couple is formed, the moment of which tends to turn the vessel on a longitudinal axis until the vessel is righted and floats in correct position. The flooded compartments are then pumped out and the molds removed to be used again for a similar vessel.

Progress in concrete shipbuilding has been made in Denmark also: one firm is reported to have several types from 300 to 1000 tons dead weight approved and classified by the Bureau Veritas for overseas service. The work has even developed so far that official rules have been laid down for design applying to the construction of flat-bottomed vessels of reinforced concrete.

At Montreal, Canada, the construction of a 126-ft. ship of about 350 tons capacity was started early in September, 1917, by the Atlas Construction Company, Ltd., and the vessel launched in November. This ship has a beam of 22½ ft. and a depth of 12½ ft. The ribs are of structural steel encased in concrete and spaced about 27 in. apart, the steel sections being 5 in. deep at the top and 14 in. at the base. Before the plans were prepared by C. M. Morssen, president of the company, and Prof. Ernest Brown, of McGill University, tests on model ship beams were made to ascertain the resistance of concrete to some of the strains encountered in ship design. The shell is of reinforced concrete varying from 3½ to 5 in. in thickness, approximately 50 tons of reinforcing steel being used in construction. The concrete is reported to be practically a mortar, about 1:1½:3, with small gravel. It was placed between forms, construction being carried on as continuously as possible. The vessel is of the single-screw type capable of about 8 knots.

The concrete vessel to which probably the greatest interest attaches at present is a 336-ft. single-screw cargo steamship of about 5000 tons capacity being built at Redwood City, near San Francisco, by the San Francisco Shipbuilding Company. The ship has a beam of 41½ ft. and a molded depth of 30 ft., with a designed load draft of 24 ft. She is to be fitted with Scotch boilers and triple-expansion engines of 1750 hp., giving a speed of 10 knots. Fuel-oil tankage is provided sufficient for 30 days' steaming.

The hull is divided into nine watertight compartments by concrete bulkheads. The frames or ribs of the hull are spaced about 4 ft. apart and there are also interior columns for the support of the two decks. The shell is reported to be about 5 in. thick at the bottom, decreasing to 4 in. at the deck, which is about 3½ in. thick. In addition to the diagonal-rod reinforcement in the shell, wire fabric is placed ¾ in. from the outside surface.

According to recent reports concrete is now being deposited in the forms, using a 1:1½:2 mixture with ¾-in. maximum size coarse aggregate and carefully graded sand. During the placing of the concrete the outsides of the forms are hammered to thoroughly consolidate the concrete and produce a dense surface. After stripping the forms the hull is to be sand-blasted and given a coating of gunite, later finished by rubbing.[1]

Although several firms in New York City have been developing plans for barges, the first construction work of this character was begun by the Louis L. Brown Company last October on a 700-ton deck scow of length 112 ft., beam 33 ft., depth 10 ft. and light draft 3 ft. 4 in.

The frame of the barge consists of reinforced-concrete members supporting a thin concrete shell reinforced with wire mesh. Rail, bulkheads, and deckhouse are of concrete; wooden fenders will be used. Concrete is placed by means of a cement gun.

Construction of a 500-ton scow will be started shortly at Vancouver, B. C., the plans having been prepared by the Taylor Engineering Company, of that city. This has an overall length of 107 ft., beam 32 ft., and depth 9½ ft. It will draw 3½ ft. light and 8½ ft. when loaded to capacity. The truss method of framing is of interest. The same company is now designing a 1200-ton well-deck scow. A New Orleans sand and gravel company is now building a deck barge 130 by 30 by 7½ ft. deep, of about 550 tons dead weight.

A joint committee of the American Concrete Institute and the Portland Cement Association has been investigating this subject in a preliminary way. It recently prepared a report covering points to be considered in designing concrete vessels and submitted a tentative design for a 2000-ton seagoing barge of the following dimensions:

Length	227 ft. 6 in.
Length between perpendiculars	220 ft. 0 in.
Beam	42 ft. 0 in.
Depth	23 ft. 0 in.
Loaded draft	18 ft. 0 in.

The displacement was estimated to be 3675 tons on an 18-ft. draft. The vessel is divided into five compartments by transverse bulkheads, the three center compartments being for cargo and the other two for tank and ballast.

In designing, the criterion followed was a steel ship designed according to Lloyd's rules, and practically equivalent strength provided in reinforced concrete. A concrete of 1:1:2 mixture with carefully selected sand and selected gravel (about ½-in. size) was decided upon and considered to develop an ultimate crushing strength of at least 3000 lb. per sq. in., allowing a maximum stress in concrete of 1000 lb. per sq. in.

The spacing of the frames is 4 ft. and the thickness of shell 4 in. on the sides and 5 in. on the bottom. Two lines of reinforcement are provided. The deck is 3 in. between hatches and along the lines of the hatches and 5 in. thick outside these lines.

[1] Since this was written, word has been received that the hull has been completed and the vessel successfully launched.

An estimate of quantities gave the following:

Concrete	731 cu. yd.
Steel	482,000 lb.
Flooring for hold	30,000 ft. B.M.
Oak timber (fender rail, etc.)	15,000 ft. B.M.

The total weight of the ship was estimated to be 1647 tons and the carrying capacity 2028 tons for 18-ft. draft. The cost of the hull per ton dead weight was estimated at $63; the best available figures indicated a cost of steel hull of the same character of $90 to $120 per ton and up; cost of wooden hull of $70 to $100.

A few paragraphs from the report of the joint committee are given below and may be of interest in regard to points connected with the design and construction of concrete vessels.

"It is apparent that the efficiency of a ship as a cargo carrier depends upon the relationship between dead weight and displacement. Expressed in terms of per cent, in the average cargo ship built of steel, the dead weight is from 70 to 75 per cent of the displacement—taking into account as weight of ship all spars, fittings, deck houses, anchors and chains, auxiliary engines and tanks, but not boilers, engines or coal. In a wooden ship, the dead weight is from 60 to 65 per cent of the displacement. It is quite evident that from the difference in weight of materials, it will be difficult to design a ship of concrete that will give a relationship between dead weight and displacement approaching that of steel. However, if ships are to be built of concrete for commercial use, the weight of the ship must be such as to provide a reasonable dead weight or cargo capacity for the displacement.

"The stresses in the transverse members of a ship are, in still water, functions of the draft and the stiffness, and may be computed by mathematical processes, although the computations are long and laborious. When the material is reinforced concrete the problem becomes much more complicated. Experience has shown, however, that numerous elements other than draft affect the transverse strength of a ship, such as the effect of rolling in a sea way, impact with docks or other ships, and stresses incident to going into drydock. The transverse members of cargo ships of today are, therefore, not designed to withstand computed stresses, but are designed in accordance with various rules which embody the result of long experience in the construction and use of ships. It should be noted in this connection that granting of insurance depends on compliance with these rules."

"Steel ships are of two different types, (*a*) framed ships, in which transverse ribs or frames are spaced from 18 to 24 in. on centers, the plating being riveted to these ribs without intermediate longitudinal members, excepting in the bottom; and (*b*) longitudinally framed ships (Isherwood), in which heavy frames are spaced from 10 to 15 ft. on centers, with intermediate longitudinals to which the plating is riveted."

"From a comparison with the ordinary steel-ship design, it would appear to be not difficult to design transverse members of reinforced concrete of equivalent strength to steel members—the question of strength only being considered."

"A ship must be able to meet conditions which are unlike any to which land structures are subject.

"In determining the longitudinal strength of a ship, it is customary to assume two conditions. Under the first condition, the ship is assumed to be suspended between two wave crests, the length between crests being equal to the length of the ship between perpendiculars, the height of the wave being equal to one-twentieth of that length. In this case, the ship as a whole is acting as a simple beam supported at the ends. This condition is termed 'sagging.' Under the second condition, the ship is assumed to be supported amidships on one crest of the same wave. Under this condition, the ship as a whole acts as a cantilever. This condition is termed 'hogging.' It is apparent, therefore, that when a ship is riding the waves both the deck and the bottom of the ship will be required to withstand tensile and compressive stresses alternately—the maximum tensile stress following the maximum compressive stress at very short intervals. In a steel ship the entire cross-sectional area of the midship section acts to resist these stresses, taking into account, in determining the moment of inertia, all of the continuous members, such as continuous scantlings and deck, side and bottom plates. In the concrete ship equivalent strength must be provided. In the case of the concrete ship, however, only the steel reinforcement can be relied upon to take tensile stresses. The concrete, assisted by the steel, will take the compressive stresses."

"There is an almost unanimous opinion among naval architects and seafaring men generally that a concrete ship will be so inelastic that she will tear herself to pieces in a sea. While it is doubtless true that in a concrete ship there will not be the same readjustment of stresses as in a steel ship when subject to the action of a heavy sea, experience with reinforced-concrete structures generally has shown that such structures have considerable elasticity, and there is ample reason for the hope that reinforced concrete will prove a suitable material for shipbuilding purposes."

One of the questions in concrete shipbuilding concerns the possible effects of sea water on concrete. Recent investigations by the Bureau of Standards, as reported by Messrs. Wig and Ferguson, throw new light on this subject and point out remedies. The results of their investigations tend to show that inferior concrete, or concrete of which the surface skin has been impaired, suffers serious effects when in contact with sea water, and that great care in the mixing, placing, and finishing of the concrete is needed for durable construction. There is every reason to feel assured that the care needed in the selection and proportioning of materials and in mixing and placing and finishing concrete for concrete shipbuilding will provide the proper remedy.

Another aspect is the protection afforded the reinforcing steel by the concrete, and in this connection the investigations of the Bureau of Standards show that portland cement itself is durable in sea water, which suggests that the rich mixture of concrete used in concrete ships, if properly deposited around the reinforcing steel, will provide the requisite protective coating.

Besides the work now under way which has been mentioned, plans are nearing completion for the construction of other vessels on the Gulf and Southern Atlantic coasts, so that in the course of six months there should be much more detailed information available on the subject. The art of concrete shipbuilding might be said to hold the position occupied by reinforced concrete fifteen years ago, but the knowledge gained during these years is helping to solve the present problems, and we may be sure of a rapid development in this hitherto unrealized field.

In the report of the Canadian Department of Marine and Fisheries for last year, recently made public, the opinion is expressed that no form of industry has a brighter opening in the Dominion than shipbuilding, and it has in fact already made a rapid and substantial start.

Ships to the value of $60,000,000 to be constructed in the Canadian yards this year are reported to be already under contract. Included in this amount are orders for vessels amounting to $25,000,000, placed on behalf of the Admiralty through the Imperial Munitions Board; 100 others are under construction at plants in various cities throughout the Dominion, as well as certain craft regarding which information cannot be given. In this situation of the shipbuilding industry, necessitated by the demand for tonnage to meet war conditions, the British Controller of Shipping, the British Admiralty, the Imperial Munitions Board, and two departments of the Canadian Government have had a part. (*Journal of Commerce*, March 14, 1918, p. 5.)

THE WAR'S EFFECT ON MERCHANT SHIPBUILDING

By HOMER L. FERGUSON,[1] NEWPORT NEWS, VA.

In a military sense, this war is narrowed down to the question as to whether the German submarines can sink the English ships and those of the Allies at such a rate as to force peace upon Great Britain, ourselves and the other Allies before the Germans are sufficiently thrashed on land to recognize that fact. When the submarine campaign was started in February, 1917, the German Minister of the Navy promised his people that in August of that year England would be brought to her knees. The rate of sinking for a time increased until it became probably three or four times the rate of building.

There have been two schools of thought regarding the proper method of meeting the German submarine campaign. One school has held that only by the production of the maximum number of ships in the shortest space of time, until the production of new vessels should more than equal the destruction of vessels in being, would the question be answered. The other school has held that there were vessels in plenty to feed England and to carry our troops to France and to feed them, and that the proper method to meet this menace was to build a large number of submarine chasers, destroyers and other vessels of war to go after the submarine itself.

The exponent in an official way of the theory of building the maximum number of ships is, of course, the United States Shipping Board, with the Emergency Fleet Corporation as the largest individual owner and builder of merchant ships anywhere, either at this time or at any other time in the history of the world. All of the shipbuilders have had their new ships commandeered by the Shipping Board, and these ships are now being pushed to completion under the direction of the Shipping Board. In addition to the ships under construction at the time the Shipping Board took over all these vessels on August 3 last, the Shipping Board has placed contracts for 200 to 300 additional steel ships and for about 200 wooden and composite ships. The English have built ships at a very rapid rate during the past six months, but prior to that time their capacity had fallen off woefully. The figures of British shipbuilders are that in normal years their capacity in tons was about two million. In 1915 they built only 700,000 tons. In 1916 only 550,000 tons. In the first six months of 1917 they built 500,000 and by the end of 1917 they will have built during this year almost two million tons, or practically their normal tonnage.

In comparison, it is interesting to look at our record, which is mostly to be made in the future. The largest tonnage ever built by us in any year prior to 1917 was in 1908, when we built 615,000 tons. In 1917, or at the end of the fiscal year of 1916-17, on July 1, the total tonnage turned out in merchant ships in this country was close to 800,000 tons. Of course, we expect this to be bettered very much, and except for labor difficulties the production would have been very much greater; but it is a far cry from 800,000 or 1,000,000 tons of ships a year to a prospective 2,500,000 to 5,000,000 tons of ships a year, and especially when we consider that the best the first shipbuilding country of the world ever did in any one year was only 3,000,000 tons.

Now as to the methods of turning out such an enormous tonnage in a short time. The standardized ship was first thought of by Noah. It certainly would have been had he built a second ark. Every other shipbuilder has thought what a joyful thing it would be if he could only build two or three or four ships just alike. If the war does nothing else for shipbuilding, it will at least demonstrate that the individual tastes of individual owners need not be met in every instance. Building a ship is somewhat like building a house, and I dare say even the ladies present will agree with me that none of them has ever seen a house built which they would not change here and there—certainly in closet space if nothing else; and it is very much so with ships. Ships are not built alike for the reason that ships are built by units and tens instead of by thousands. And what applies to the automobile industry or hat industry, or any other industry where the units are small and the aggregate number is very large, is not possible where you are building a thing that is worth half a million or a million or more. It is certainly not possible under ordinary circumstances with a very scattered ownership. But with a single ownership, like the Emergency Fleet Corporation, it becomes possible for the owner to specify that all ships shall be alike, and thus we have standard ships!

There is an idea extant that if a ship is called "fabricated" or "standardized" it becomes rather easy to build. It does become easier to build, but it is not any easier to drive a rivet in a fabricated ship than in a common ship, and the 7500-ton fabricated ship will have about 650,000 rivets and some riveters must do a considerable amount of work to drive those rivets in that ship the same as in any other ship. The most onerous work in building a ship is in the driving of the rivets; and if any concern is going to build one ship a week it must drive 650,000 rivets a week. When we consider that the best rivet drive is by the Union Iron Works, where they drive 250,000 rivets a week, and the next best by the three largest shipyards on this coast is about 200,000 rivets each per week, the problem of driving 650,000 rivets a week assumes a rather difficult aspect to the casual observer.

The fabricated ship has the center of the stage at the present time. In England a standardized ship was adopted which is very much like a fabricated ship, and they are being turned out at a rapid rate. The first ships have already been completed and are now on the sea. The fabricated ship, like the English standard ship, has the disadvantage of low speed, and at the same time it has the advantage of a large carrying capacity. The records of submarine sinkings, such as have been gathered, indicate that speed is probably the safest defense against the submarine. The number of very slow ships sunk is very great in proportion to the number attacked. Probably 90 per cent of the slow ships are sunk when attacked by a submarine. As the speed becomes greater the immunity of the ship from torpedo attack becomes greater—not only because she presents a more difficult target, but also because the vessel may run away from the submarine in darkness or in daylight if she has a greater speed than the submarine has on the surface, and also because the vessel may be maneuvered much more quickly.

One of the most gratifying things about submarine warfare is that the torpedoes are not making as great speed as in the early days of the war. The speed of the torpedo has undoubtedly become much decreased. Just why we do not know, although it is probably due to the absence of tungsten and

[1] President, Newport News Shipbuilding and Dry Dock Company.
Abstract of address delivered at a joint meeting of the Engineers' Club of Philadelphia and the Philadelphia Section of The American Society of Mechanical Engineers, October 16, 1917.

manganese and some other ingredients now so difficult to obtain in Germany. Vessels of 16 or 17 knots have actually dodged the torpedoes.

The vessel of 16 or 17 knots is also needed to carry soldiers. We are shipping all our soldiers to Europe in vessels of 14 knots or over because it is thought to be too hazardous to ship them in the slower vessels. We have at the present time in this country enough vessels in commission to ship soldiers to Europe at the rate of not more than one million a year. That includes all vessels of 14 knots or over. But by building a large ship, as well as a speedy ship, an additional factor of safety is obtained, which may be illustrated by stating that a torpedo will blow just as big a hole in a little ship as in a big ship. When a small, short ship has a large hole in it, a relatively larger proportion of its length is open to the sea. When a similar hole is blown into a long ship, a very much smaller proportion of that vessel is open to the sea. So that it is perfectly possible to design, and practical, indeed, to design a ship 500 or 600 ft. long, so subdivided that it will take two, and probably three, torpedoes of the German variety and still stay afloat.

The design, however, must be of such character that when the compartments are flooded the ship will still remain upright. The requirements of passengers who go to sea are such that the ordinary passenger ship shall have a very small metacentric height. But with a small metacentric height the rolling of the vessel is very easy, so that the passengers are not made ill with the motion of the ship as easily as they would be if there were a large metacentric height and the ship rolled quickly and with a jerk. Ordinary passenger ships are modeled with a small metacentric height, and three-fourths of them, when bilged or torpedoed, will probably turn over before sinking.

A great deal of talk was heard years ago, when the *Titanic* went down, about making ships safe. The *Titanic* was probably the safest ship that ever crossed the ocean, with the exception of the *Olympic*. The *Empress of Ireland*, the *Lusitania* and the whole host of passenger ships of which we have any record have turned over as they went down, and they probably righted after they went down. In designing a ship that will be safe against submarine attack, not only must the question of subdivision be taken care of so as to limit the length of the vessel that may possibly be damaged by a torpedo, but also the stability, so that when torpedoed the vessel will remain in an upright position and will be able to get into port.

The larger type of ship which will probably be built before the war is over by a number of concerns in a position to undertake this work will be designed with a high speed for troop transport, with a close subdivision to make the ship safe, and with a large amount of stability so that the vessel will also be safe against turning over.

The war so far has developed three distinct types of vessels: the standardized or fabricated ship, such as both England and the United States have adopted; the large troop transport which has been described; and, in addition, the submarine chaser.

Besides these three types there has been a very definite attempt to rejuvenate what some of us have considered a dead industry. I do not know whether many wooden ships are being built around Philadelphia, and I would not like to criticize the wooden-ship builders; but I should like to see a few. We have a few of the older wooden-ship builders left, but the building of a wooden vessel to my mind is so much more difficult than the building of a steel vessel, and requires so much higher skill than does the building of a steel vessel, that I wonder how one can ever expect to build them.

I do not believe that a 288-ft. wooden ship built in a lumber yard, either South, West or North, and necessarily by men who are not expert ship carpenters, will ever relieve any great distress on the other side of the water caused by lack of fuel or food. On the other hand, these wooden vessels may be used in our own trade at home. My chief regret is that they are not made shorter, because when such ships are over 200 ft. long it is rather difficult to hold the ends up. If we can get more vessels by building wooden ships, let us build them, but it is unfortunate that the type was settled before many professional wooden-ship builders were on the job. The wooden-ship builders, of course, have taken a good many men from the steel-ship yards, and have lessened production to just that extent; but, on the other hand, they will add a very considerable tonnage, now that practically all our large coastwise ships are either going abroad or are in the way of being commandeered for foreign service, so that the wooden ship will serve a useful purpose.

The standard ship probably offers the best opportunity for a large increase in our tonnage. The standard ship has been built on the Great Lakes for years. Shipbuilding there has become largely a manufacturing operation for the reason that the ships themselves simply form a part of the manufacturer's business of carrying iron ore from Lake Superior down through the Canal to the eastern points, where it is shipped to the steel furnaces. The loading and unloading of the ore permitted the standardization of docks, hatches, and so on, and the method of construction became standardized because the work which the ship did was standardized. Many ask why we do not build ships just as they do on the Lakes, and the answer is that we do not do the same work that they do. On the coast, with the coal trade, there has been some effort toward standardization. With the standardized ship the main benefit is not in the hull of the vessel, or in the fabrication of the vessel in the steel mill. The main benefit is that the machinery and the outfit, the winches, the pumps, the steering gear, the engines and boilers, and all the thousand and one things that go into the ship, are standardized, and may be produced in large quantities at some point other than the yard of the builder. The standardization of the fittings of a vessel is more important to my mind than the standardization of the hull. The amount of money saved in the latter will be that required to build the templates, patterns, etc., amounting to not more than $12\frac{1}{2}$ to 15 per cent of the labor cost of the hull. We are told, too, that all the riveting will be done at the steel mills. It probably will not, and if 20 per cent of the riveting is done there, it will be more than I think, unless the railroads will carry pieces of steel as large as this auditorium.

Shipyards have naturally tried to standardize within their own practice the fittings that go on the various ships they build, and a great step is being made in that direction by one of the largest corporations in the country. The Bethlehem Company own so many shipyards that they are in a position to standardize as between their various yards, with the result that there will be considerable saving in cost and in time in the production of all the things that go into a ship.

But in building the standardized ship, or in building any other ship, the real problem is not the problem of equipment; it is not the problem of money even; it is not, except in part, the problem of location, but it is the problem of men. A very simple lesson in arithmetic will indicate that if 100,000 rivets are to be driven in one day, and any one gang of riveters will drive 300, then it will take so many men and boys and helpers

to get that drive. It is quite desirable to get back to our arithmetic again when we have built so many ambitious high hopes of what we expect to do. I can state for our company that the most fortunate thing we did when this war started was that we promised to deliver ships only in the quantity that we had been delivering before.

Saying that we are going to do a thing does not do it, and *hoping* that we are does not do it, and promising to the newspapers that we are going to build all these ships does not do it. As a matter of fact, enthusiasm and high hopes, unless counterbalanced by good judgment and experience, do more harm than good, because a good many people are lured into a sense of security that we are going to win against this submarine menace, when, as a matter of fact, there is nothing to justify any such conclusion. For instance, on the Delaware and on the Chesapeake, which we, on the Chesapeake, are pleased to consider the two largest shipbuilding communities in the United States, there are at present about 33,000 men employed in the shipyards. There could be employed to advantage in these same yards at this time a total of 48,000 men, and within the next six months, or the next nine months at the latest, these same yards, barring the fabricated shipyards, could employ to advantage a total of 60,000 men. So the problem becomes arithmetical again. There are 32,000 men working. To get the maximum production out of the shipyards already in existence, 60,000 men will be needed. Where are the 28,000 extra trained shipbuilders to come from? Add to these shipyards the fabricated shipyards, which on the Delaware will probably require 20,000 men, and in the vicinity of New York an extra 10,000, and we have in this immediate district need for approximately 60,000 new mechanics in the shipbuilding business.

According to Admiral Capps, there will be needed in the whole United States in shipbuilding within the next six months an additional 150,000 men. Now consider for a minute where these men must come from or how we are to get them. In the first place, most shipbuilding men or mechanics require both skill and experience. We can give them the experience fairly quickly, but we have not time to give them the skill. In other words, it is necessary that men be recruited from industries where they do work similar to the work of shipbuilding. I say other industries without specifying what particular industry. Of course, it would be natural to pick the non-essential industries, if there are any such. But I would say that they should be taken from *any* other industry if necessary, because our problem in the war becomes the most difficult when the question of transportation is considered.

We are operating or preparing to operate 3000 miles from our base, and that is the crux of the whole question. A reasonable solution has been proposed for every physical problem presented by this great war except the problem of oversea transportation. The problem of oversea transportation absolutely has to be met before we can get into the war effectively, and the problem of sea transportation is probably the most difficult of all problems we have to face. Therefore, the men should be furnished for the solution of this problem, no matter what industry they are taken out of. We are making a fine, large army; we are making all kinds of quartermaster supplies and guns, and other things, but none of them are of any use whatever unless carried to Europe. Our soldiers must be carried to Europe, and not only that, but the soldiers that are carried to Europe must be fed and must have ammunition. The excitement created by the war so far will be but a gentle zephyr compared to the excitement that would permeate the United States if, perchance, we should get a million men in France from the United States and they should go hungry. My own opinion as a plain American is that that is the largest problem that looms up in the future. It is a military problem of prime importance—the most important single problem that confronts us at the present time.

I have been quoted in an extract of this talk that I gave to the newspapers as favoring the conscription of laboring men. I do not say that I favor the conscription of laboring men, but I do say this—that sooner or later the United States will tell all men who are essential in any industry or any occupation in the prosecution of the war that *this* is their job, and they are to stay by it until the war is over. It is ridiculous that our men who are already in Europe and those who are going there now should suffer on account of some difficulties that arise between employers and employees in the great shipyards of this country. Not only should the man who pounds iron and drives rivets be told that he shall be kept on his job, but also every employee in the company, from the president down to the office boy, that he is to do the same thing, and is not to seek or obtain other employment, except for good reason given the Government authorities. It simply comes down to this: Whether we are playing a game of amusing ourselves, or whether we are in to win. If we are in the war to win, no one should be timid about telling the laboring man or the unions, or anybody representing them, just what part they have got to play along with the part that other people should also play. In fact, when the war started a few of us in conversation with the Secretary of the Navy told him that we thought the thing for him to do was to commandeer the shipyards, together with all their employees; to put us all on the Government payroll if he wanted to do so, and give us as many stripes on our uniform as he thought proper, and if we did not do as he thought the United States wanted us to do to court-martial us and send us down to Atlanta or some other convenient penitentiary. And I think something of that sort should be done. Any man who has charge of shipbuilding or engineering in any capacity who is not perfectly willing that that should be done both to himself personally, as well as to his men, has a very one-sided view of this war which needs to be corrected. Of course, it is held by the National Council of Defense and by a number of exalted bodies that the *status quo* as between employer and employee should remain the same during this war. Of course it should remain the same, and we all know that it is not remaining the same, and we all know that the labor leaders, as a rule, are unable to control the men.

There is a solution of this labor problem effected with the transport workers on the other side; Liverpool, for instance. A number of the soldiers were sent back to Liverpool and went to work. A few years ago in France a great threatened strike on the railroads was settled by making soldiers out of all the railroad employees. Our present stevedore troubles are in a fair way of being settled by giving the colored man a chance to be a stevedore instead of being a soldier in the trenches; and so far as I have been able to observe in our neighborhood, several thousand of them are glad to take advantage of this glorious opportunity, and are stevedoring for their country very quietly and very effectively. I do not see why of all the men who have been passed into the National Army that we should not have in so essential an industry as shipbuilding those of them who are mechanics on conditions set by the Government, and on pay to be approved by the Government, to work in these shipyards until the war is over, or until they should perchance prefer to go to the front instead of staying in the shipyards.

I understand that in Philadelphia it is very difficult to have

any of the shipyard employees excused from military service. Of course, they have their own rules to go by in Washington, and we must all abide by them, but it is rather unfortunate that they should be differently interpreted in different parts of the country, and it seems to me most unfortunate that the shipbuilders have been allowed to go to the front. The experience of England was that they had to take out of the trenches not only the shipyard workers but the ammunition workers, and send them back to the factories again. It is a pity that we could not profit by that, but I suppose we will after we have gone a little further into the war. That would be a solution that would help very much with this laboring-man difficulty.

Of course, the real trouble with the employers of labor is they are told that they must get together with the men and must have no trouble during this war: that they must keep the plant going. Every manager that I have talked with feels that it is incumbent on him as a good American to see that the wheels are kept going around and that these ships are produced, and I dare say that all the employers are perfectly willing that they should fight with their own laboring men, and fight to a finish if need be, except at this time. We all know what that means. The demand is largely in excess of the supply of men. The sympathy of the Government is with the men. At our Navy Yard, under the law, we pay the going rate in that vicinity, and arbitrarily fix the rate at a larger rate than the going rate in the vicinity which we have to meet. and we are told in case of difficulty we must keep going, so it is only a question that can be worked out by the Government's representatives and the shipyard employers together.

I would be perfectly willing to see all the shipbuilders go down to the Navy Department and Shipping Board and say, "We will agree with you on these conditions and stand by them, and will shut up our shop before we pay any more." Of course, it can be said that a man who works is entitled to any wage he can get. Perhaps he is, but he is not entitled to stop working now, and he is not entitled to say that any other man shall not serve an apprenticeship now. He is not entitled to say that a helper shall not do a mechanic's work if he can do it. How perfectly ridiculous when a million and a half of the best young men that we have in the whole United States are serving an apprenticeship in the war, leaving their homes and going out to learn the art of soldiering in a very short time, and quite as difficult work to learn as riveting. What a ridiculous thing to say at a time like this that a man cannot get a job unless he has served his time at the trade, and tie the hands of the United States in this great war, which it must win if you and I are going to keep on being proud of living in the United States.

I was shown today in the case of a number of workers that the money which they could earn in a day was limited by the organization to which they belonged, and that if they earned that much money at two or three o'clock in the afternoon they would work no more, notwithstanding the fact that the management wanted them to do it. When will people ever learn that production by the use of labor-saving machinery to get a large production per man is all that gives us more than we ever would have otherwise, or than we ever would have had before the days of large production? And yet they have limited production with the idea of giving more jobs to more men in time of war when we have not got enough men and have about three jobs for one man!

I will take just a little bit of your time in presenting what I might say is the worker's side of the story. I do not know the conditions in Philadelphia, but I imagine they are rather bad for laboring men. As an instance of what can happen, in Newport News, a town ordinarily of 30,000 people, we now have 55,000 people. The place is so full of people that no one can even go there to see the soldiers off. The condition of laboring men who are gradually coming in from the West to all the seaboard towns is a very difficult one, and a great deal of the basis of discontent is a lack of suitable housing conditions. That is ordinarily taken care of in the towns and cities by real-estate people and those who build for investment, but at the present time that method is wholly inadequate, and this question will have to be considered along with the same program as that for our Army which is being installed in cantonments all over the United States. Why? Because we cannot find vacant houses for 20,000, 30,000 or 40,000 men in any one place, and so quarters have to be provided the same as for the soldiers.

The Government is waking up to this situation in the case of some recent contracts let for destroyers. The Government itself will finance the building of barracks or temporary hotels for the men, so that several hundred can be housed at or near the shipyards where the work is to be done. For instance, in Philadelphia you have large fabricated plants to be built, and you have a number of large war industries settled here. In addition, Essington will need probably 20,000 men and the fabricated-ship yards probably 20,000 or 30,000 more. It becomes necessary even in this city, which is known all over the country as the best workmen's city in the United States, that the housing be looked into, and that large additional facilities be quickly provided. One of the biggest problems England had was the formation of new communities and the building of whole towns. In some cases they were almost ten miles square, and in them were provided not only ordinary houses and living accommodations, but public parks, playgrounds, theaters and everything needed in a modern town.

[Mr. Ferguson continued by referring to the need at this time for patriotic service to the country on the part of all alike, regardless of the group or individual. He could not imagine the United States letting stand in its way any band of men whatever when National honor and life depend on our winning this war, and we are sending our young men to France by thousands. The Government might exact any toll so long as all were treated alike and business was left with enough money to carry on its operations, pay a moderate return to the owner and be able to serve the Government in the best way.]

The Chamber of Commerce of the United States, representing many business men of the country, at its meeting at Atlantic City, gave voice to this sentiment: that if they treat us all alike they could not go too far in exacting the greatest toll from the business of the United States. We are willing to have the plants commandeered by the Government, under the terms of the United States and under conditions which they see fit to impose; but we insist that managers, foremen, superintendents and men shall all be treated alike.

With reference to the difficulty in securing priority in the delivery of material. I would say that we have received from the Navy Department and from the War Department and from the Shipping Board orders to proceed with the utmost vigor and despatch to do their work, each in the same tone of voice, each with equal authority, all vested in these various departments by Acts of Congress, so that actually what has happened is that the president of our company has had to settle the question of priority himself—an entirely improper function for him. The question of priority and preference is now the biggest industrial question there is, for

the very simple reason that the total production of the United States has been over-absorbed by these war activities.

With the prices settled, the only important thing is, who gets his first, who second and who third. The Government wants to get the material in such quantities as it can, but it is simply impossible to satisfy all these bureaus and departments. What is the answer? The answer that was found in Great Britain in the very first months of the war was to divorce the question of business, buying and price-fixing from the naval and military activities of the country. A munitions minister was appointed; just the kind that we need. The same chamber of commerce I was speaking of recommended that a board be appointed. I am a director in that chamber, but I think a minister should be appointed, because you want a *man* who will coördinate the interests of the country, and when blankets are necessary he will buy blankets for the United States, and not buy three blankets for the sailors and none for the soldiers.

The weakest point in the shipbuilding business is the forging situation, in my judgment. There are not enough forges in the United States to turn out all the forgings required for the shipbuilding. The great Bethlehem Company, Midvale, and the Allis-Chalmers are practically the only large ones we have, whereas Great Britain has twelve or fifteen very respectable forging concerns. It is absolutely necessary that some one determine whether this or that or the other kind of forgings shall be first; otherwise a lot of us are apt to end up with hulls but with no machinery to put in them. It seems to me that we all want to do the best we can, but we would very much appreciate it if we could go to Washington and say to some one that this is the most important, and that is the next, and that is the next. Instead of that, we appeal from one department to another, and the result is that we frequently end up with nothing.

I hope that the good people in Philadelphia will always maintain an open market for beginners in the shipbuilding industry, and when the Shipping Board works out its program of breaking in new men and bringing them in from the West, then every one in our business will do his best to give a helping hand. We invited the Board to bring its school to Newport News. I think they have been invited by one or two Delaware shipyards to establish a school for the instruction of teachers who would go back to their home yards to break in all of the new help. We have to break in large numbers of new men, and the most important question next to the housing question is the breaking in of these new men, and our foremen and superintendents must get used to the honor of subjecting themselves to the discomfort and inconvenience and annoyance of breaking in large numbers of perfectly green, raw country boys.

We all know that it is a joy to have a few good mechanics and give them a job and forget about it, but we have to get away from that and to teach new people, which may fortunately be done with ships of standard make and duplicate makes. The problem that the employment managers have at the present time is to get hold of the best material possible, house it as decently as we can, and teach it shipbuilding as quickly as possible. The problem almost dazes one to contemplate. It can only be solved by bringing in enormous quantities of new men, and which must be done without any hindrance. The leaders of the unions have stated that they would allow this to be done. We have to do it, and no matter what else happens we must insist upon the right to break in any number of new men in the business. The Shipping Board will back it up, and I am sure that sooner or later the Administration itself will insist upon that being done on such a comprehensive scale as to make it possible for the United States to carry out its great shipbuilding program, which *must* be carried out.

OUR INDUSTRIES AND THE WAR

A Timely Discussion Before the New York Section on the Open Question of the Adjustment of Our Industries for Effective War Work

FACED with the diametrically opposed conditions, on the one hand that several billions of dollars are being spent by the Government upon manufactured products for war purposes, inflating and seriously taxing one set of manufacturing resources and, on the other hand, rendering it necessary to limit production in other lines not directly essential to winning the war, and the disruption of those organizations, the industrial situation today calls for an adjustment which, if not approached from the standpoint of the welfare of the nation, is liable to produce, and has unfortunately already produced, disaster in some channels. The common ground for attack of the two-sided problem is, of course, unbounded patriotism and the desire to win the war as soon as possible, and it is to the credit of the manufacturers mostly concerned—the small manufacturers whose activities are at the present time apparently not available for mass production—that they have approached the problem on this ground, and many have made sacrifices worthy of the cause. At the same time, however, there is the other side—the protection of our industrial organization as a stabilizing element during the war and a subsequent economic necessity.

With the hope of developing some of the facts in the case as a means of bringing out some constructive suggestions to meet the problem, the New York Section of the Society organized and conducted an impartial meeting on the evening of February 21, to which a number of prominent manufacturers were invited to express their views. The following is a brief account of the protracted meeting, which culminated in a definite recommendation to the Council of the Society to take action in the form of appointing a committee to act as a clearing house to bring the requirements of the Government to the industries, so distributing work that the resources of the nation would be made completely available.

GEORGE K. PARSONS, in opening the meeting, said that it was to be regretted that the term "non-essential" had ever been applied to industry, since it was misleading. Essentiality is a relative term, and no industry exists which cannot contribute in some way to the demands of war. He cited a report from the London *Economist*, showing that while luxuries were now less in evidence in Britain, no British industries had been destroyed—they had merely been converted. He said that organized professional engineers could and must use their peculiar and particular abilities in publicly and privately helping industry to accommodate itself without upheaval to the problem of winning the war, and to help the

Government in such a way as to make the application of drastic measures unnecessary. The object of the meeting was therefore to see how engineers could promote the essentiality of the various industries.

Secretary Rice emphasized this object by stating that it was the duty of engineers to help solve the problems of the Government. It was especially their duty to discuss the subject of conversion of the industries, as it was impossible to carry out such conversion without an engineering analysis. He said that industrially the problem of the Government is to secure the necessary supplies for the conduct of the war. The second problem is to insure continuance of our industrial strength during and after the war. He described a plan of the Fuel Administration which, by applying fuel curtailment to certain industries, automatically provided restriction of non-war industries. This plan had already proven practicable, and industry had given its hearty support to it. The actual effect of the plan was to limit production of non-essentials.

President Main congratulated the Section for taking up its share of public work. He hoped that the meeting would result in some constructive suggestion which could be made to the owners of non-essential plants, who were looking to engineers for assistance in getting the Government to utilize their facilities for making, perhaps, small parts of munitions.

Frederic W. Keough, editor of *American Industries*, official organ of the National Association of Manufacturers, declared that it was impossible to prepare a detailed classification of essential and non-essential industries, as there was no such thing as a non-essential industry. Many products which seemed at first thought to be non-essential in wartime might be just the things to send abroad instead of gold in exchange for essential raw materials. He thought we all ought to be eager to promote war work, but in doing so there was no occasion to tear down our industrial structure which we would probably need very badly to meet foreign competition at the end of the war. Manufacturers generally were not only "doing their bit," but were doing their utmost of their own accord to convert their plants to war purposes and to supply men for war work. He urged that no drastic action be taken to curtail industry, but that the engineers tell the manufacturers how adjustments may be made with the least friction and waste so that all their resources may be applied to the common good.

Horace B. Cheney, of Cheney Bros., South Manchester, Conn., wrote that it might very well be that the industries most necessary now for military success would be of the very least value at the termination of the war, and when that time comes we must not find our industry in a position from which it will be unable to arise and quickly meet the ordinary business of life. He thought it was possible to make a rough estimate of what the Government needs for war purposes, such as ships, munitions, clothing, food, etc., and what the civil population needs, beginning with food, clothing and shelter, and what the country needs or may need directly after the war and thus arrive at an idea of the relative value of industries. The best way to find out how an industry can be of most use in the war is through the trade associations, which are already in many instances conducting distribution of raw materials as well as furnishing information regarding stocks and needs of industries.

Past-President Hollis said he had never been able to distinguish between the essential and the non-essential industries. He said that while a great many of the smaller industries had been willing to make sacrifices and to help in the war, it had never been made quite clear how they could help best. He thought it was for the engineer to instruct the manufacturers and the public in that particular so that no industry would be sacrificed unnecessarily. He thought that one essential industry which the Government had more or less lost sight of was the "college industry." Up to this time no way has been found by which our boys who are being trained to take their places in the industries can be left free to obtain their training without the feeling or imputation that they are slackers. He thought that our Society could help out in this situation by educating the people as to what is best for the future.
